THE BUSY MAN'S PAGE

Violas from Cuttings.

AT the beginning of August it is a good plan to cut back one or two plants of the various sorts of violas, in order to encourage the production of young shoots. These shoots will form excellent cuttings and, in all ways, are better than those taken from the flowering stems. The cutting may involve the sacrifice of a few blooms in the case of a few plants, but it will be found to be well worth while. If the season is dry, water the treated plants to stimulate a vigorous growth. As a rule, the cuttings will be ready for taking about September, and this is a very good time to carry out the business of propagation. Let the shoots be from 2ins. to 3ins. long and insert them in sandy soil in a cold frame. The frame should be kept close until the cuttings show signs of having taken root; then as much air as possible should be admitted, and, even in wintry weather, unless the conditions are very severe, ventilate the violas, which should never be coddled. In this way good sturdy plants will be ready for putting out at the end of March.

Thinning Seedling Wallflowers.

THE importance of sowing wallflower seeds thinly cannot be over-emphasised. It it in the seedling stage that the plants run the greatest risk of overcrowding, and drawn plants are always unsightly, especially when planted, as is often the case, in beds where they are most often seen. True it is that many think any kind of soil will do for wallflowers, and that fact, perhaps, in no small measure accounts for the leggy and for the stunted plants which are often seen at planting time. Certainly a rich soil is not required, but a seed-bed into which leaf-soil has been worked, and of which the soil has been finely broken up, will well repay the little extra trouble involved. The leaf-soil will serve to retain moisture in the seed bed, and when transplanting time arrives it will be seen that the young roots are most abundant where they came in contact with the leaf-soil. If, after sowing, seedlings come up thicker than was anticipated, thin them out early, for if only two or three hundred plants are required there is no point in allowing them to become weakened by the unwanted surplus. As the seedlings are coming along, attend to the preparation of the plot on which they are to be pricked off. Here, again, leaf-soil may be generously applied and the ground should be nice and moist at the time it is used.

In many gardens it is the practice to prick off wallflowers in the evening, and such a practice has much to commend it, for then, if well watered, the young plants are transferred to their new quarters without that flagging of the leaves which is so noticeable in those plants which are shifted during the heat of the day. In pricking off allow plenty of space between the plants, for it must be remembered that the hoe must have room to work if the best results are to be obtained.

ROW OF SEEDLING WALLFLOWERS READY FOR TRANSPLANTING.

METHOD OF TRANSPLANTING, EACH PLANT HAS SUFFICIENT ROOM TO GROW AND DEVELOP.

How to Pot Some of the Early-Flowering Bulbs.

A FEW bulbs may be potted in July, but the second week in August is quite soon enough to begin this work in earnest. A few years ago the well known Freesia refracta alba, deliciously scented, was grown mostly, the coloured sorts not being as good as the strains of them are to-day. Directly the cultivator receives the bulbs he should pot them without undue delay, as their strength is conserved in the soil better than in any other way. The conditions, at first, must be as cool as possible. The compost most suitable is one of loam 2 parts, leaf-soil 1 part, and well rotted cow manure 1 part. Five, six and seven inch pots may be used, the middle size being the best in every way. Both pots and crocks should be very clean and dry when used, and the compost medium. As a guide to the potting, a space of 1in. between the bulbs will do, and the latter should be planted in 1in. deep; then, in cool conditions, the first new growth will be quite sturdy. Empty pots or boxes should be placed inverted over these and all other kinds of potted bulbs, to keep off the covering sand, ashes or soil. Early Roman hyacinths may be potted now and in a similar kind of compost. Five small or four large bulbs will be sufficient for a 5in. pot, and seven small or six large for a 6in. one.

Soil Mulching.

AS a rule, during the early part of the season, there will be no great need for mulching. It is in the later summer and autumn that the soil in many gardens becomes so dry, as seriously to hamper the growth of plants. Of course, the dryness may be combated by watering, but this may well involve more labour than the gardener is able to expend. It is just here that mulching proves of valuable assistance, for, if the layer is properly arranged, plants may be well supported even over a long dry spell. Mulching, of course, consists of covering the surface soil with some loose material, such as lawn clippings, straw, leaves and, where it is wished to feed as well, a layer of manure. This loose material draws up the moisture from the subsoil to the surface and so keeps it in a damp state; the roots of the plants are then under almost ideal conditions, and their well being is reflected in the vigorous growth of the plant. With light soils, mulching with manure is of great value in the case of sweet peas, roses, etc., for it will keep them in bloom for a much longer period than would otherwise be the case. Then, nearly all fruit bushes and trees are benefited by summer mulchings. Size and quality of fruit depends to a large extent on the amount of moisture which the plants secure during the summer. When the weather finally breaks up in the late fall, the mulch, which will by this time be largely decayed, can be dug into the soil and so add to the store of humus content.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Madonna Lilies.

THE habit of the Madonna lily is to develop leaves in the autumn, and its rest period is between the flowering time, July, and the commencement of new growth in late August. It is, therefore, at this season that this popular lily can be most safely moved. If a clump of lilies is already flowering well, and is not too crowded, the bulbs should not be disturbed, as they resent disturbance, and the flowers during the first season following removal of the bulbs are usually inferior. But, of course, the time does come when clumps must be lifted and divided.

Never plant the Madonna lily in low-lying, badly drained soil. It does not mind the soil being rather poor, provided it is well drained, and contains a fair amount of lime.

Great care must be exercised when lifting the bulbs. The best tool is a wide-pronged potato fork. Separate the bulbs from each other, and carefully prepare the site before replanting. Add flaky leaf-soil and sprinkle a layer of sand before setting the bulbs in position. They should be about a foot apart in groups of six or seven, and 4ins. deep.

AUGUST IN THE TOWN GARDEN.

WHAT TO DO THIS MONTH.

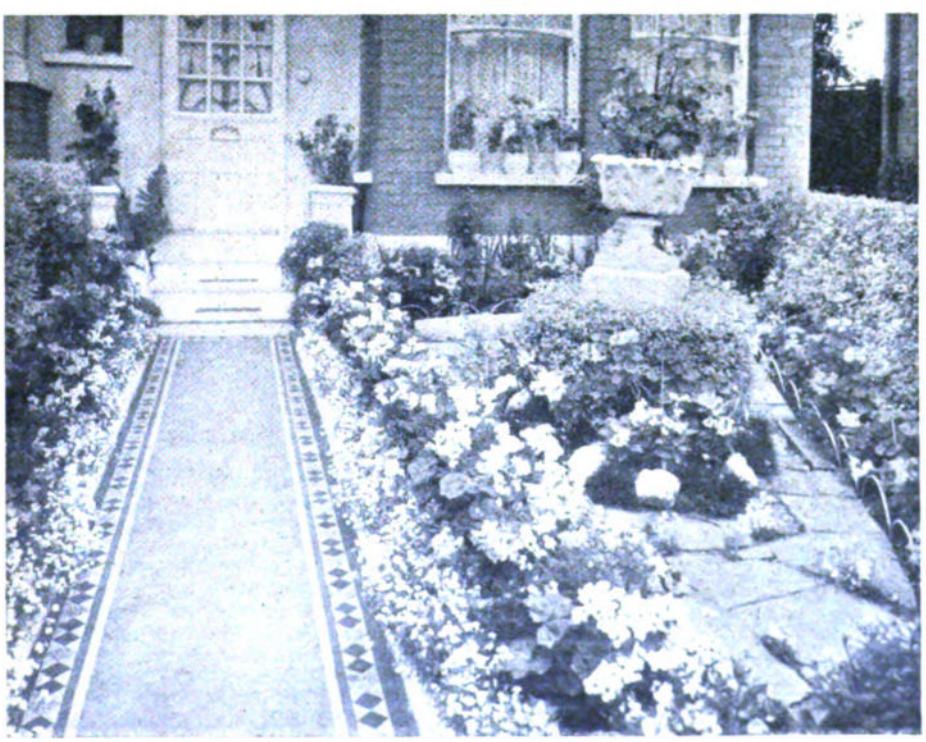
1. *Sow seeds of hardy annuals and biennials, such as Orange King Calendula and Canterbury bells.*
2. *Take cuttings of bedding plants like geraniums and pentstemons.*
3. *Thin out weak growths of dahlias and tie main shoots.*
4. *Where necessary, transplant Madonna lilies.*
5. *Feed roses of the hybrid tea type to secure an autumn crop.*
6. *Cut out old flowering wood of Wichuraiana roses, and tie in new growths.*
7. *Bush fruits will require thinning. Cut out old canes of raspberries, and thin the suckers.*
8. *If weeds are thoroughly removed from the garden this month, there will be little further trouble until autumn digging is done.*
9. *Sow salads for late autumn and winter use. Hardy Hammersmith is the best lettuce for winter crops.*
10. *Sow onions for next season. Thinnings can be used for salads.*
11. *Earth up celery as required.*
12. *Sow seeds of spring cabbage. Harbinger and Ellam's Early are good varieties.*
13. *Lift early potatoes. Remove diseased specimens and dry before storing.*
14. *Keep side shoots pinched out from tomatoes.*

Taking Cuttings.

A NUMBER of our most valuable summer flowers are easily propagated by means of cuttings. Golden and brown calceolarias, pansies and violas, pentstemons, and Salvia splendens are a few of the most popular garden flowers increased in this way. After the recent rain, there is an abundance of side shoots suitable for making into cuttings. Select those of sturdiest appearance, with four or five pairs of leaves. Remove the two bottom pairs of leaves and cut the stem just below a joint. If a cold frame is available, this can be prepared to receive the cuttings. A mixture of equal parts of loam, leaf-soil and sand, with a sprinkling of lime, is the most suitable; but ordinary rich garden soil will do if a liberal sprinkling of sand is scattered over the surface after it has been finally stirred and levelled.

Where boxes are employed, these should be 4ins. deep, and with ample provision for drainage. A layer of fibre, sifted from turf, or of half-decayed leaves, is placed in the bottom of the box before the soil is filled in. Never fill the box full of soil, but leave an inch space for watering.

Cuttings are most easily inserted with the aid of a pointed stick. They should be well watered and protected from drying winds immediately. In a frame or under a hand-light or cloche, this is most easily effected. Shade the cuttings from bright sunshine for a couple of weeks, and as soon as the first sign of growth is observed, give all the ventilation possible. Cuttings of the plants mentioned above may be as close together as 3ins. apart; but geraniums would require 4ins.



CALCEOLARIAS MAKE AN EFFECTIVE DISPLAY IN A SMALL FRONT GARDEN IF ASSOCIATED WITH OTHER SUMMER BEDDING PLANTS.

Reflections on Autumn Fruit Planting.

HOW often does one hear the lament of amateur fruit growers, "Oh, I have some fruit trees, but we never get any fruit." Nor is this lament confined to amateurs. I know a Kent cherry grower whose earliest trees seldom bear good crops. *Elton Heart* is the variety, and its flowers are over before the *Napoleons* and *Amber Bigarreaus* are in flower. No matter how carefully the ground is prepared, nor how clean and healthy the trees are kept, the whole business of fruit culture fails if only sterile trees are planted. A little example of the importance of cross-pollination was on view at the Chelsea Show this year. The experiment was a plum tree, one branch of which had its flowers cross-pollinated with those of another variety, and another branch was entirely self-pollinated. The increased number of fruits on the cross-pollinated branch was remarkable.

When selecting fruit trees for planting, varieties should be chosen that will flower at the same time, or cross-pollination cannot take place; or if only one tree can be planted, a self-fertile variety should be chosen. A few such among apples are *Irish Peach*, the juiciest and earliest dessert apple; *Stirling Castle* and *Lord Derby* (cooking). A selection of four apples which would pollinate each other, two dessert and two cooking, would be *James Grieve*, *Cox's Orange*, *Early Victoria* and *Bramley's Seedling*.

The law of self-sterility not only applies to apples and cherries, but to all fruits. If a fruit tree flowers well each year, and yet bears no fruit, I should advise planting also a different variety which flowers at the same time. A list has been prepared by the Librarian of Wye Agricultural College, giving the flowering dates of different varieties of fruits. A few given as flowering at the same time are: Pears—*Louise Bonne of Jersey* and *Fertility*; plums—*Monarch* (self-fertile) and *Coe's Golden Drop* (sterile); cherries—*Napoleon* and *Frogmore*.

NOTES ON THE FLOWER GARDEN

An Iris for Pot Culture.

(Iris tingitana.)

THIS is a handsome bulbous iris from Tangiers, which is admirably suited for the border and pot culture. For the latter purpose I can strongly recommend it, and, moreover, it may be had in bloom from Christmas onwards, in fact, by introducing batches to the greenhouse at fortnightly intervals, the supply of flowers can be kept up for several weeks. This desirable iris somewhat resembles a large-flowered Spanish variety, the frilled standards range from dark to light blue, and the falls are lilac shaded white, with a yellow blotch. It attains a height of 18ins. to 2ft., and last January, I had blooms quite 6ins. across. Only 2 per cent. of the bulbs failed to produce a spike, so either as a pot plant or for cutting purposes, it has much to recommend it. September is a good month to pot up a few and five roots will be ample for a pot 6ins. in diameter. Provide ample drainage and the rooting medium consists of a mixture of loam, leaf-mould and sand. When the bulbs are potted, stand the pots in a cold frame and afford water in moderation till root action is evident, and a fair amount of top growth is visible. Towards the end of November they should be removed to the greenhouse, where the temperature is between 50 degrees and 60 degrees, then the spikes will soon appear. A cooler house will do equally as well, but, of course, the flowers will be later. Where a quantity is needed for cut bloom, fairly deep boxes can be employed instead of pots. I. tingitana will also succeed outside, especially at the base of a warm south wall, but the soil should be of a gritty nature, and when planting let each root rest on a little sharp sand.

This iris should be grown largely where flowers are desired in the early part of the year.—CHEPSTOW.

IRIS TINGITANA, A BEAUTIFUL IRIS FOR GROWING IN POTS.

Plants For Dry, Hot Situations.

IN most gardens there is generally one spot at least which may be described as hot, fiery and easily dried up. Such a place is not always satisfactorily filled with flowering plants, and I put forward here a special claim for the sun roses and the rock roses. The former, helianthemums, are undoubtedly plants of the sun, and they revel in a site which receives its full rays, flowering with continuous and astounding profusion in the height of summer. The shrubs—they are really dwarf shrubs—have a trailing habit, and they soon cover the ground with compact tufts. Among the choicest of a fairly extensive list of varieties I place The Bride, Double Carminatum, Attraction, Warrior, Fireball, mutabile, multiplex, croceum, Double Orange and Jubilee. For the driest place I would reserve the old yellow vulgare, or Tuberaria, or the double venustum. The rock roses are dwarf shrubs also, equally floriferous and in every way as satisfactory as the above in hot and trying situations. Most of those I grow are fairly tall, the height varying considerably but always being about half normal in porous hot places. This list may not be up to date, but I like florentinus, cymosus, crispus, ladaniferus, lusitanicus, creticus, algarvensis, incanus and corbariensis. A good catalogue will reveal colours; the helianthemums are much more brilliant than the cistus or rock roses.—H. H. A.

A Blue Pimpernel for the Rock Garden.

(Anagallis Monellii.)

THOSE readers on the look-out for a fine blue flowering plant cannot pass by the above pimpernel. It is a native of southern Europe, and has proved perennial here at Castleford, while so far it has not set any seeds. For some reason it does not figure in many catalogues, and I first saw the plant at the Chelsea Show in 1923, when examples were eventually obtained the following year from Messrs. Whitelegg of Chislehurst. On the rock garden it is only a few inches high, with a tendency to trail over a rock, and throughout the summer it is a mass of brilliant blue flowers about ½in. in diameter, with the merest suspicion of a yellow "eye." Plants in 6in. pots have been used for furnishing the front of a staging in a cool greenhouse. Here the trailing growths have been over a foot in length, and a mass of bloom for several months. It is, however, a plant for the sunny rock garden, and for the last three years it has not been afforded any protection during the winter months. A. Monellii is readily increased from cuttings, and they will soon form roots in a cold frame or hand-light. A batch inserted last August are now making a brilliant display on the rock garden.—T. W. B.

Planting St. Brigid Anemones.

YIELDING a profusion of blossom at a comparatively barren period of the year, the St. Brigid anemones are undoubtedly popular and among the most useful of our garden plants. The colours show a very high range of variety and practically every one is of a bright, striking tint; attractive in the border they are equally fine when cut, not merely on account of their attractive colours but because they last so long. The culture of these windflowers is of the simplest: corms or bulbs are procured at this time or as soon afterwards as possible and are planted 2ins. deep and 3ins. to 6ins. apart. Before planting, it is advisable to turn the soil over to a good depth, for the plants give of their best in a well drained site; it may be necessary, also, to add some decayed manure to it and a fair sprinkling of old mortar rubbish or weathered lime. As they are best suited by a medium to light loam, growers who have a heavy soil can take steps to ameliorate it when they know that fact. In the growing season it may be necessary to apply water, for dryness at the root is inimical to complete success. In most districts the first planting may be made in late August and further lots put in during September and October; other plantings may be made after the New Year, and so, by a little preliminary manipulation, it is possible to have flowers from January until midsummer; late February until May is the main flowering season, however. I advocate a good mixed selection which, with its rich reds and its black centres, singles and doubles, gives a truly Oriental touch to the garden.—CLYDESDALE.

The Blue African Lily.

(Agapanthus umbellatus.)

ONE cannot help having a kindly feeling for the agapanthus, a plant which remains healthy and flowers exceedingly well with maximum inattention and lack of care. It grows on and continues to flourish for years without repotting, indeed, it may grow until it cracks the pot and absolutely demands attention. Generally speaking, however, it should be repotted and, if required for increase of stock, divided every three years. The compost found best is a turfy loam, enriched by one-quarter of its bulk of well broken up old manure, with, perhaps, a little sand to aid porosity. Always repot in a pot which allows 1in. of soil between the roots and the sides, all round, and pot firmly; before doing this, wash the old roots free from soil. Large plants may be put in tubs. Feed plants the second and third summer with liquid manure; water as required, but dry off the plants in winter, never allowing the soil to get dust dry, nevertheless. In mild districts the African lily can be planted outside, where it will do well in a kindly border; roots must be thoroughly protected in winter. The usual home for the plant, however, is a cool conservatory, where it grows splendidly and merely needs protection from frost. The heavy heads of blue flowers are a delight in summer, and its tough green leaves make it attractive and ornamental at all times.—LANARKSHIRE.

Topical Notes on Herbaceous Flowering Plants.

Getting the Best from Them.

IT is not claimed for the hardy herbaceous border that it is the only one in the garden that gives pleasure; but it is submitted that, if planned and planted with a view to continuity and to the value of its blossoms for cutting, it will, if given attention at the right periods, furnish flowers that will remain attractive over the longest time.

We have now reached the half-way stage of garden beauty, when a deal may be done in giving a freshness to the borders during the next few weeks. In some of them it is not unusual to introduce a few things like antirrhinums, which bring rich colourings in early autumn days. If we are satisfied with leaving them in the state they were planted, and letting them take their chance, we shall have few flowering spikes, because of our neglect to remove seed pods; and the same obtains in a degree with certain herbaceous plants that, once relieved of the dead and dying spikes, will take on a new lease and yield further flowers—perhaps not so fine as the first, but welcome in the garden, nevertheless, when autumn flowers proper take their place.

Mention is made of such plants as Veronica spicata, Spiræa Filipendula, the creamy flowers of which rise from out a cushion of fern-like foliage; some of the achilleas, like Ptarmica the Pearl, or the single form of mongolica; the orange-flowered biennial, Cheiranthus Allionii (Siberian wallflower); and certain of the erigerons—all of these, though accredited with blooming well on into autumn, sometimes fail to do so with anything like freedom unless they are persistently relieved of the flowering stems as they die away. One thinks, too, of the bellflowers, such as Campanula persicifolia, that soon exhaust themselves unless steps are taken to cut away the flowers that have gone past their best. Pyrethrums are good second flowerers, especially the singles, when given a chance to show their capabilities. These are a few of the plants in the hardy flower border that, if treated as suggested, will renew themselves in the autumn, and give bloom, adding variety among other flowers in the days when Michaelmas daisies, kniphofias, helianthuses and anemones appear, with their train of colour beauty. Even these should not be permitted to go to seed, as to do so prevents the development of buds that will yield the latest flowers in the garden.

Current work consists in giving a stimulus to the plants. It will mean, first of all, eliminating all spent flowers, the forking of the border and freeing it from weeds, the staking of anything that needs support, and generally in imparting a tidy appearance all round. It is the extra that we do, over and beyond what actual duty demands, that tells in the late days of autumn.—W.

Delphiniums for the Summer Border.

A BORDER of delphiniums shows them to their very best advantage. The accompanying illustration was taken eighteen months after the plants were sent from the nurseryman. The border, which forms part of a new garden made in an old paddock in Essex was thoroughly trenched and some good manure added as the work proceeded, a good dressing of lime was forked into the surface after the trenching was completed. The planting was done in September. Many of the spikes were over 2ft. long, and no doubt the thorough working of the ground accounted for the very fine spikes of bloom in this border.—E. J. S.

Autumn Among the Phloxes.

WE are apt to say to ourselves, when we see certain flowers opening in the garden, that autumn is not a long way off. Phloxes are among the number, and, though some of the early summer blooming sorts are very charming, it is to the later section (decussata) that we must look to keep up a supply of flowers from early August until the time when frosts appear and rob them of their beauty. In a mild season, one may have the trusses quite late, especially if the garden be a sheltered one. For many years phloxes have been looked upon as indispensable in the herbaceous border, sharing honours with other back-row plants. They vary from 3ft. to 4ft. in height, are easy to cultivate, and are good subjects for a town or suburban garden. Best served when they can be given a moist soil, rich in humus, and a sunny position, in a period of drought, they are often punished, unless steps are taken to mulch the roots with something that will help to conserve moisture, such as leaf-soil, old manure, glass clippings and the like. They enjoy copious supplies of water, and when they are approaching their blooming stage benefit considerably by applications of liquid manure, which must be given in a weak form only.

Division of Roots.

The finest trusses are produced from clumps which are not allowed to become too large, as, if left to themselves beyond a couple of years without being taken up and divided, the flowers from the centre of the plants are small and puny from inability to derive enough nourishment. This, obviously, means that if the grower of phloxes is wishful to have spikes of the finest quality, he must arrange to take the clumps up periodically, reduce the size and, if possible, plant them in fresh quarters. Though division of roots is one and, perhaps, the most practised way of increasing the stock of plants, it ought not to be overlooked that one may also propagate them from cuttings. These should be taken in spring, when the shoots are about 3ins. or 4ins. long, and inserted in pots of sandy loam and leaf-mould and placed in a cold frame. Division ought also to be made in spring, as the new growth begins to show, and in doing this preference should be given to the shoots on the outside of the clumps, which are always strongest, the centre shoots being left out of account. A phlox with about a dozen stems is more likely to give the better flowering spikes than a clump with twice the number of shoots. Staking plants is not always looked upon as necessary, but it is helpful in rough weather. It need not involve treating every shoot in this manner, but three or four canes to a clump around which twine can be tied will often prevent breaking of promising shoots.

A DELPHINIUM BORDER EIGHTEEN MONTHS AFTER PLANTING.

Varieties.

It is not the intention to burden the reader with a long list of the very many good varieties of autumn phloxes now in commerce, but to select a few, having regard to their diversity of colour. Here, then, is a short selection:

Admiral Jaures, lilac mauve.
William Ramsey, violet blue.
Border Queen, flesh, with red eye.
Thor, salmon red.
Milly Van Hoboken, soft pink.
Flambeau, orange scarlet.
William Veitch, white with crimson centre.
Mrs. Jenkins, pure white.
Grossclande, dark purplish scarlet.
Simplon, salmon carmine with purple centre.
Leonardo da Vinci, pure white, maroon centre.
Elizabeth Campbell, pale salmon, fading to pink.
Baron von Heeckeren, rosy salmon, large truss.

In getting the clumps in fresh quarters in spring, the ground should be previously prepared by deep digging, incorporating with it rotted dung and road scrapings. Especially is this needful on shallow, sandy soils.—W. L. L.

CLUMPS OF HERBACEOUS PHLOXES IN ALL COLOURS MAKE A DECORATIVE DISPLAY AT THE HOUSE ENTRANCE.

Digitized by Google

PRIMULAS FOR A WINTER DISPLAY IN THE GREENHOUSE

What the Plants Require at the Present Time.

PRIMULAS, when well grown, are a great asset to an amateur with a small greenhouse, as, with comparatively little outlay and very trifling heat in winter, he may have a gay display for months. At the present time, plants for winter and spring blooming should be in their final pots; although, as a matter of fact, late sown seedlings can still be given their last shift, and these will, of course, provide the latest flowers. Five or six inch pots will be found large enough for the purpose, and the essentials for the work are: clean pots and crocks, old loam two parts, leaf mould one part, with a little rotted dung and coarse silver sand added, the whole being passed through a sieve, the roughest portions being placed at the bottom of the pots. The pots ought not to be filled to the brim, but an inch or so of space left, which will enable further food to be added as required.

P. OBCONICA, A MOST USEFUL AND DECORATIVE PLANT FOR THE COOL GREENHOUSE.

Summer Situation.—There is nothing better than a cold frame in a north aspect for primulas during summer and early autumn, but it should be away from overhanging trees, which are liable to make the plants become weak and drawn, besides exposing them to "drips." The base of the frame can be covered with fine ashes on which the pots can stand, and this will obviate the need for a too frequent watering, as the ashes will help to conserve moisture. Though frames are needful to bring on these plants, it does not mean that one must keep the lights on; as there will be many a day when they can be moved altogether, so that air may do its part in the building up of healthy, robust specimens. The beginner with primulas should guard against overcrowding his plants in the frames. They ought always to stand clear of each other. If cramped, the leaves being so brittle and tender, are liable to get bruised or broken, and the beauty of the plant is marred. In potting, the compost should be in a nice workable state, not too wet or too dry, and it should be pressed rather firmly about the roots, afterwards giving a soaking of water.

Shading.—In very bright weather it is advisable to shade the plants from bright sun. Buds will now begin to show and these must be picked off, the main idea being to promote growth and build up the plants for future beauty.

Stimulants.—Not until primulas have become established in the final pots and the roots are getting round the sides, will it be necessary to afford stimulants of any kind, and even then they should be given sparingly and in a weak condition. A good help to them is to place sheep or cow manure in a coarse bag in a water tub and dilute this, applying it after the plants have had their ordinary watering. Once a week will be quite enough for a stimulant. Occasionally one may give them soot water, made from old soot, from which the "fire" has gone. This will be found very beneficial in promoting growth, and in imparting to the leaves a deep green colour. The amateur should leave out of account freshly gathered soot, which is likely to do more harm than good, or in attempting to give any sort of stimulant to plants when they are dry. Only when the usual watering has been done ought "pick-me-ups" to be used, and they are best administered an hour or two after the plants have had clear water. These are details, the observance of which tend towards the building up of vigorous plants, and when brought into the greenhouse towards the middle or end of September, as weather dictates, will soon begin to throw up good trusses.

Winter Quarters.—A shelf in a greenhouse, not too far removed from the glass is the best for primulas, and it will be enough for them if a temperate atmosphere is maintained throughout, as heat is not essential to their success. When they are housed, and on many a day in the late autumn one may admit air freely, as they are plants much hardier than some amateur growers imagine them to be, and to ensure a good and continued display, one has but to work at the present time on the lines suggested.

There are a number of primulas which are suitable for growing in the greenhouse. These include Primula sinensis and its many varieties, PP. stellata, obconica, kewensis and the free-flowering easily grown P. malacoides.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

HERE are a few hints obtained at the official potato trials organised by the Board of Agriculture Trials at Corstorphine, which I pass on to those readers who may be encouraged by Mr. McKelvie's success to take a hand in the work of raising new varieties. The best localities for the raising of seed crops are late, high-lying or exposed districts, where the potato patches are widely separated from each other and where, consequently, it is easy to isolate a healthy stock from diseased plants. That it is not necessary to go to the north of Scotland for such conditions is shown by the fact that excellent lots of stock seed have been grown on the west coast of Arran. Never keep new varieties in a garden where they are likely to get infection from bad plants, but grow them in a turnip field, where there is less danger of infection. Cutting of the seed tubers to every eye is not injurious to the health or vigour of the plants and this rapid multiplication is preferable to the growing of stocks in sheltered positions. The ground occupied by the Trials is prepared in winter, when 15 tons of farmyard manure per acre are applied and at planting time the supply is supplemented by 8 cwt. per acre of artificial potato manure which is deposited in the drills.

Proceeding from Corstorphine in the west to Joppa at the eastern outskirts of Edinburgh, I spent a profitable hour in the afternoon inspecting Messrs. Dobbie and Co.'s potato trials. The contrast in the condition of the plants was remarkable. The foliage was vigorous and healthy and the cover was such that the 3ft. space between the drills was inadequate for quite a number of varieties, of which there were fifty under observation. The haulm of the early sorts had begun to show signs of dying down and plants of Di Vernon and Witchhill Early which were dug had eighteen and sixteen well developed, clean and shapely tubers at the respective roots. A show of Epicure did not produce so high a yield, but here again one could not keep from admiring the clean skinned, shapely tubers that were fit for the exhibition table. Neither the second early nor the main crop varieties could be tested so early in the season for weight of crop and while all were characterised by an excellent cover, the following sorts were outstanding in that respect, *viz.*, Majestic, Great Scot, King Edward and Rhoderick Dhu. Messrs. Dobbie's stock of Arran Chief, which came from Banff, has probably no equal in the country, but Incomer is regarded as the best potato in the trials. It is a distinct white flesh, oval shaped potato of an obviously strong constitution and besides being a good cropper it is credited with excellent cooking qualities, which, after all, is one of the strongest points in favour of a potato. Individually and collectively I have never seen a better collection of potatoes or one which testified to the advantages of good culture.

The soil and situation must also be favourable, for I learn that Messrs. Sutton and Sons, Reading, have secured a piece of land in the immediate vicinity of Messrs. Dobbie's trial grounds.

With the advent of August, garden work generally becomes less strenuous. At the

Digitized by Google

same time it must not be neglected and amateurs who take a short holiday at this time should endeavour to arrange for necessary operations, such as syringing, grass cutting, staking, tying, etc., being attended to during their temporary absence. Unless these routine duties are observed, the owner may return to find his garden a wilderness and many flowering subjects damaged beyond recovery, for August has a reputation for sudden summer storms towards its close. Where there is a greenhouse the problem is more difficult to solve as the existence of the plants depends on moisture and the regulation of ventilation, which implies regular supervision daily. If a reliable jobbing gardener is not available, the best alternative is to enlist the services of a friendly neighbour who is acquainted with garden management.

The maintenance of a winter supply of parsley frequently tests the resources of the amateur gardener, as plants raised from spring sown seed and from which pickings have been made throughout the summer months seldom crop satisfactorily in winter. If they escape the common disease known as rust, which causes havoc in summer, especially when parsley is grown too thickly in rows, as is frequently the case in small gardens, the foliage is liable to damp off or be destroyed by frosts in winter. The question comes to be, how are these difficulties to be overcome. One method of prolonging the summer supply into autumn or early winter is to cut down the plants to 3ins. or 4ins. from the ground at the beginning of September, when the foliage shows signs of coarseness and thus induce a fresh crop of young leaves. This method being dependent on the weather, is attended by varying success and by far the safest plan is to transfer a few plants to a cold frame in late autumn, where they will only need the protection of lights in bad weather. When consumption justifies the practice, seed may ue sown in August in a position that is fairly well exposed as a safeguard against damp. Apply a light dressing of lime when forking over the soil and sow the seed thinly in a shallow drill when the soil is in a fairly moist condition. In the event of a spell of dry, warm weather, it is beneficial to germination to cover the drill with matting as a means of preventing the surface from drying too rapidly. Seed may also be sown in pots or boxes, which can stand outside until the approach of winter.

Visitors to Scottish seaside resorts in August are familiar with Escallonia macrantha, one of the most attractive of hardy flowering shrubs which is now at the height of its bloom. To realise its possibilities one must see it growing as hedges in Arran and other popular places on the Clyde, where it seems to revel in the sea breezes. In no other environment does it succeed so well. The glossy green foliage provides a fine setting to the drooping clusters of crimson blossoms, borne on the ends of the branches. E. langleyensis, of which E. macrantha is one of the parents, is the more graceful of the two, and seems better adapted for inland situations, for it flowers luxuriantly in Pollock gardens in the suburbs of Glasgow. This shrub grows to high dimensions and the distinctive bright rose carmine flowers carried on the upper side of long arching growths are most useful for house decoration. All the escallonias are easily propagated by cuttings of half-ripened wood taken, preferably, in September.

Since my first inspection of the sweet pea trials a number of varieties have greatly improved in size and colour, so that there may be a few surprises in store as the result of the final inspection at the show on Wednesday. Mrs. A. Searles which threw a rogue in the English trials, is quite fixed at Helensburgh and is in the running for the gold medal.

ST. MUNGO.

WHAT OUR READERS SAY

VERONICA TRAVERSII.

SIR,—What is apparently the hardiest of the New Zealand veronicas of a tall-growing habit and at the same time one which will flower in a small stage, as well in proportion as when large, is Veronica Traversii. It has been known to me for very many years, and I have seen it in numberless gardens, and in every instance it has proved quite hardy. In only one winter, and that the most severe for a very long period, did I come across plants which had suffered and these were cut to near the ground, but came away again in due time. These were very large plants about 6ft. high and as much through, and they were injured as much by the snow and by the strong sun on the frosted leaves. It says a good deal for V. Traversii also that it is used as a hedge in some gardens, and a very pretty one it forms, too. It is hardly suitable for a fence to turn cattle, but as a division in a garden it is excellent. It has pretty, glossy, evergreen leaves and spikes of white flowers in great numbers. V. Traversii is also remarkably easy to propagate from cuttings, which root very readily in sandy soil. As has been said above, V. Traversii flowers in a small stage and continues to increase in size and beauty for many years. As a hedge it will require clipping, but when grown as a bush it is best left to grow naturally, when it generally forms a shapely bush. It will grow in any ordinary soil and seems to thrive in shade or sun.—S. ARNOTT, *Dumfries*.

ROCK ROSES FOR DECORATION IN THE GARDEN.

SIR,—Many of your readers may be interested to see the accompanying illustration, which is of two plants of rock roses growing on either side of the garden steps. These are old plants and were moved with great care to their present position in March of this year to furnish the sides of the newly made steps which lead down a sunny dry bank to a semi-wild garden. The effect produced is very charming and shows the value of the rock rose in such a position.—H. R. THOMSON.

ROCK ROSES FLOURISHING ON A SUNNY BANK.

FREESIA CULTURE.

SIR,—With reference to "Claremont's" note on freesias, on page 498 of THE GARDEN, I would certainly pot freesias in July, if they could be obtained thoroughly ripened by then, but my experience of English grown freesias is that mid-August is as early as one can expect them, if properly ripened, in a sunless July such as we have had.

While I advocate August planting, I do not agree that later planting gives "weak, puny growth," and that "they are never satisfactory."

The greater part of my stock never gets planted until late September and early October when sales have finished. I do not think the plants and cut blooms I exhibit at Vincent Square each spring can be described as weak and puny. Certainly August is the best month. Seed, if sown in August, will flower in eight months, but I always grow the seedlings a second year before judging them finally.—G. H. DALRYMPLE.

AN AMERICAN LABOUR-SAVING DEVICE.

SIR,—On the best private estate in the United States of America one would, more or less naturally, expect to find sundry labour-saving devices in use, so that when I first became acquainted with Mr. Samuel Untermyer's fine estate at Yonkers, New York, I was not surprised to find that the tedious work of clipping and keeping in repair grass verges to paths, etc., had been superseded by a more efficient labour-saving device.

All the grass verges are supported by strips of iron fixed along their face. These strips are 10ft. to 15ft. in length, 6ins. in depth and ¼in. in thickness. They are partially embedded in the ground so that their upper edge is exactly on a level with the surface of the lawn. On the inside they are strengthened and supported by pegs of wood driven in at intervals, while the solid path affords sufficient support on the outer side. Where necessary the strips are curved to coincide with the winding of the verge. In appearance these strips are very neat and the verge itself is never broken down, as so frequently happens when nothing of this kind is in use. When the grass commences

Digitized by Google

to grow and hangs over the top of the iron strip, it may be cut off perfectly straight by the simple plan of running a wheelbarrow all round the verges in such a way that the wheel is always in contact with the iron strip and at a slight angle inwards, so that the scissor-like action of the iron tyred wheelbarrow on the top of the iron strip quickly shears off any overhanging grass in a most efficient manner.

Although some little expense may be incurred as an initial cost, the time and labour saved by the use of these iron strips is very great and the appearance of grass edges treated thus is much neater than under the old plan. —GREYSTONE.

PROPAGATION OF ANCHUSA.

SIR,—In your valuable paper, dated July 30th, page 506, propagation by division is given as the best method of increasing anchusa, but the last few years I have given up this method of increasing my stock in favour of root cuttings, treating my plants as biennials. I take root cuttings as for sea kale, in March, putting them in a shallow trench on a west border. They are put in quite thickly and covered with some coarse sand until they begin to break through, when I plant them in a nursery bed 15ins. apart each way. The following March I transplant to the borders, using the old ones I dig out for cuttings. Before adopting this method I had great trouble in keeping my stock, owing to so many of the old plants dying off, now the young fleshy roots found at the bottom of these are used for propagating. I find the plants obtained in this manner are much stronger and better shape than any method I have yet tried.—W. J. S.

OUR PHOTOGRAPHIC COMPETITION

Readers who are interested in our competition, which we think has been a useful feature during the last three months, are requested to send in photographs before the competition closes next month. There is still time for many excellent garden photographs to be taken.

This charming summer house forms a most pleasant feature in my town garden. It was so placed to act as a point of interest in the garden and is situated half way down the length of the lawn, which is bordered with flowers on either side. Among the flowers in the border are sweet williams, tobacco plants, Campanula pyramidalis, erigerons, spiræas, hollyhocks, pink and white Japanese single roses, dahlias, antirrhinums and so on, providing a very effective blaze of colour during the summer. The roof of the house is made attractive by growing houseleeks in the tiles. This has been done by fitting a narrow board with wire through the tiles to prevent the soil washing away.

The guinea photograph, sent in by MRS. BERGNE, 13, *Pembroke Road, W.8. This was a prize-winning garden in the recent* Daily Telegraph *Garden Championships held this year. It gained the second award in it particular class.*

Below the house windows this pretty border of lupins, delphiniums and stocks in various shades has been made. It looks particularly well in this picture and provides a succession of colour and bloom during three or four months. The stocks are eminently suited for a position below a window. The garden is only fifteen months old. MR. L. H. SAUNDERS, *Church Lane, Kingsbury, N.W.9.* Award of 5s.

This photograph illustrates the charm of well planned and constructed rose arches. A walk such as this forms a restful feature in any garden. On the right-hand side, the walk is flanked by a border of mauve catmint. MR. G. E. WESTWOOD, *Hemel Hempstead, Herts.* Award of 5s.

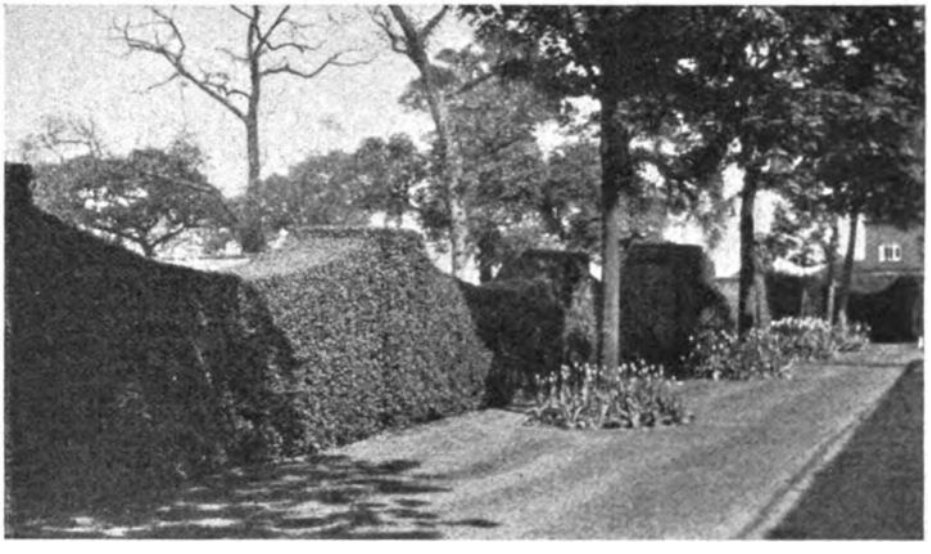
The accompanying illustration shows the lily pond in the grounds of Littedal Hall, Caton, near Lancaster. It indicates what may be done within the limits of a comparatively small garden. The grass margins have been planted with a number of moisture-loving plants, while a quantity of aquatics have been planted in addition to the water lilies, which have provided a most brilliant display this summer. MR. H. DEWHURST, *Bradford, Yorks.* Award of 5s.

A SMALL WATER LILY POOL.



This picture illustrates an effective method of growing tulips, and now that planting time is approaching it may not be without interest. The bulbs have been planted round the base of sycamore trees with a privet hedge cutting off the kitchen garden. The tulips add a touch of colour to the wide stretch of green lawn and they are shown to advantage against the background of the hedge. MISS M. HUGHES, *Lea Hall, near Chester.* Award of 5s.

MAY-FLOWERING TULIPS IN A PLEASANT SETTING.

The pink and white lavatera shown in this illustration is a charming subject for a border. It provides a most effective colour display, which is greatly enhanced by the lavender bushes in the foreground. On the left is a clump of Cineraria maritima with pink sweet williams behind. MRS. R. HAYNE, *Weymouth.* Award of 5s.

A DECORATIVE BORDER OF PINK AND WHITE LAVATERA.

THE FRUIT AND KITCHEN GARDEN

Wasteful Crops.

EVERY year, and in almost every garden, there are crops, useless and indeed, harmful. Much nourishment is taken away from ordinary crops by common weeds, and we have to fight against them without any rest from the task. But there is no excuse for allowing useless crops to remain in the garden, impoverishing the soil, and there are many such at this season. The peas are gathered from certain rows, but the old plants are left in the ground; a good rain comes and they begin to grow again from the base. The haulm should be pulled up directly the pods are gathered, the soil loosened with the Dutch hoe, all weeds cleared off and a good dusting of soot applied. Level any ridges and sow turnip seeds. There are some good yellow-fleshed varieties as well as white, which quickly come to maturity at this season. The potatoes should be lifted directly they are matured enough, and the ground planted forthwith with winter greens. Old lettuces that are running to seed rob the soil of much goodness. Do not cut, but pull up these, and sow radishes in the plot. Old stumps of cabbages and cauliflowers are, perhaps, the greatest robbers of the soil. When these are pulled and burned, fork in some well-rotted manure and sow turnip seeds, as the resultant plants will get the benefit of such surface-manuring. The same remarks apply to all other kinds of plants that are now useless. Their place should be taken by winter greens or quick-maturing autumn crops, however simple the latter may be. One of the most useful for late planting is Earliest Of All Savoy. The plants will do well at 18ins. apart each way. Many vacant plots may be occupied by lettuce and endive. Plant at 9ins. and 12ins. apart respectively.—HANTS.

Feeding and Finishing Late Grapes.

PERHAPS the amateur cultivator has a better opportunity to finish late grapes than early varieties, if he can command a fair amount of fire heat and some good liquid manure. There is a long season of growth for late grapes and the ideal early autumn weather is a splendid ripening agent. Every main leaf and every bunch should receive full benefit from both sun and stimulant. To this end all sub-lateral shoots must be removed while they are very small. At this season they grow rapidly on healthy vines and soon cause an over-crowded state of foliage if they are not regularly removed. Both white and black grapes, such, for instance, as Black Alicante and Muscat of Alexandria, are greatly benefited if four good waterings are given, in one month, of diluted liquid manure. The black grapes require the natural covering afforded by their main leaves, the white grapes require practically full exposure to the sun: the exposure being gradual by the placing aside of the main leaves. Alternate waterings with concentrated artificial manures, according to the instructions given with them, will be beneficial; but such manures should not be applied at the same time as the liquid manure. As the berries approach full maturity the borders should be covered with a thin layer of dry litter to keep down excessive moisture. On bright days when the air feels warm more front ventilation should be given to cause a nice current of air to pass through the house. One inch of ventilation at the front will be enough throughout the night and 2ins. at the top and, if the pipes are kept just warm to the feel of the hand the conditions for a perfect finish will be attained.—GEORGE GARNER.

Late Sown Peas.

THE produce from late sown peas is usually so excellent that it is worth giving the crop a little extra attention. The two chief difficulties with which these peas have to contend are drought and mildew. To an extent watering will combat dryness, but a far better plan is to resort to mulching. A good layer of any material like straw manure or lawn clippings, should be placed along each side of the rows and this should be about 15ins. wide. Before placing the mulch fork the ground lightly and unless there has been rain recently, give the soil a good soaking. After the placing of the mulch the moisture will be sufficiently conserved in the soil to enable the plants to develop and mature the crop. Mildew should be treated at the first sign of its appearance as the trouble will spread rapidly with disastrous effects. One way of dealing with the attack is to dust the plants well with flowers of sulphur just before sundown or in the morning, before the dew has dried from the foliage. A more certain way is to spray the pea plants with a solution formed by adding one ounce of sulphide of potassium to three gallons of water.—S. LEONARD BASTIN.

Lifting Early Potatoes.

THERE is nothing to be gained by leaving early potatoes in the ground after they have finished growing and the skin has become firm enough to resist pressure when rubbed with the fingers. On the contrary, there is risk of serious loss through disease and secondary growth. Vacant ground is generally needed for successional cropping and the opportunity that enables the grower to get the most from the soil must be given due weight. The best plan when lifting the tubers is to sort them into three sizes, the largest for eating, medium sized for seed, and the smallest for animal food. Those for planting next year should be selected from the most prolific roots and they will be all the better for not being over-ripe. Leave them on the ground for a day or two and then store in single layers in shallow boxes in an outhouse or spare room, which need not be dark. The eating tubers may be stored in a heap in a cool place, or, if the quantity is small, in bags or boxes, but with these darkness is essential to prevent the skins from becoming green and the tubers useless.—J. C.

Blanching Celery and Leeks.

DURING the past few weeks these plants have grown very freely because the soil was warm and recent rains saturated it and thus favoured the free growth. Very early celery will be blanched already, but the main-crop plants and the leeks will be free from soil or other blanching material. Inexperienced cultivators hasten to heap up soil to the rows of plants thinking, by doing so, that they are encouraging the growth. Often this placing of soil to the plants retards growth as the roots are robbed of much-needed moisture. The best policy is to keep the plants growing as freely as possible and as late as possible in the year without any earthing-up. The outer, worthless stalks should be removed and all weeds. Clear water and liquid manure should be given regularly in dry weather and about eight weeks prior to the date when the celery is needed for use, place brown paper bands or soil round the plants to blanch them. With one hand grip the plant and hold it tightly while any soil is being placed to it, then none of the soil will fall into the centre and, being enclosed there, cause decay. Do not tie up the sticks, but press the soil very firmly against them. If brown paper be used do not tie it on too tightly, but leave ample room for the due swelling of the sticks. A mixture of fine ashes and sand placed close up to the stalks will prevent the latter being eaten by slugs. All plants, previous to the earthing up, should be soaked with liquid manure. Leeks should be treated similarly and only seared leaves removed.

Winter Parsley.

BY sowing seed in August in a spare frame, plenty of fresh green leaves may be had during the winter. Break up the existing bed of soil and add a layer 2ins. thick of good rich compost over the surface. Potting soil is excellent. Sow thinly in shallow drills 9ins. apart. Hard, firm growth should be the aim, and the lights should be left off till the weather makes protection necessary, and even then—except during hard frosts—they should be propped open a few inches day and night. Remove yellow leaves and take the whole of the stems when gathering for use.—J. C. C.

The Perpetual Fruiting Raspberry.

THIS is a very useful plant in every fruit quarter. When well managed, the canes bear abundance of fruit. Last year, towards the end of the summer, the young canes were fastened to their supports and will now have finished bearing fruit for the present year. If left uncut they will prevent light and air reaching the young wood, which is now bearing young fruits, some even not out of flower. Cut out all the wood of last year's growth and simply retain the young. Tie the latter to strong supports, fastening them so that the canes will be evenly disposed, then light, air and sunshine will penetrate and there will be more likelihood of the crop maturing. This year, especially, sunshine is badly needed for all fruits, even those growing under glass. The extreme tips of all fruit-bearing canes may be cut off now so that the whole of the strength of the plant will be concentrated in the development of the berries. It will be beneficial to the latter if a surface mulch of half-rotted manure be applied at once, as when rains come the manurial properties will be washed down to the roots and the latter will be kept in a regular condition of moisture.—G.

Harvesting Shallots.

THESE are grown in many gardens more extensively than in past years, and remarkably fine bulbs are cultivated. If the latter are carefully harvested they will keep sound longer than summer-grown onions. The bulbs should be lifted and laid out on their sides with roots towards the south. If left exposed so for four days the ripening will be complete and they will be ready for storing. But the weather may not be bright and settled. The bulbs must not be left in the ground any longer even if the weather is adverse. Lift them and spread them out thinly in a cool, dry shed, on the dry ground for preference. Failing a shed, make use of a spare frame light, elevating the latter on empty inverted flower-pots or bricks and spread out the shallots thinly underneath. An ordinary frame will answer well if it can be spared. Left for one week under glass lights where air can reach them freely the bulbs harden well and quickly, and are ready to be graded and separated. The central ones and those that are single, even and very firm at the crown should be stored separately for future stock for planting.—CHRISTCHURCH.

THE AMATEUR'S GREENHOUSE

Stocks for Flowering in Winter and Spring.

Sow Seeds During This Month.

IN these days there are many annuals grown in pots for the decoration of the dwelling-house and cool greenhouse, and among them the stock is particularly noteworthy. A good reliable strain will produce a large percentage with double flowers, but even the singles are very useful for house decoration when other blooms are scarce. Stocks are easily grown and satisfactory in every way, and owners of cool greenhouses would be well advised to try a batch of these fragrant flowers. The section known as Beauty of Nice is admirably suited for the purpose, and this stock may be obtained in a variety of colours, which can be depended upon to come true from seed. I have grown most of them, but Old Rose has proved very popular, it is a very attractive shade of rose which would suit most people. All the Year Round is a pure white variety with wall-flower leaved foliage and is quite distinct. Perhaps the East Lothian stocks are not so well known as pot plants, but it is an easy matter to produce fine specimens some 18ins. across in pots 6ins. and 7ins. in diameter. There are several varieties of East Lothians, such as scarlet, pink, white, mauve and mixed.

When and How to Sow the Seeds.

These should be sown in boxes of light soil during August, and allowed to germinate in a cold frame, admitting plenty of air directly the seedlings are visible. When they have made three or four rough leaves, transfer them to 3in. pots, using a mixture of loam, leaf-mould and sand. It is said that the strongest seedlings are more likely to produce single flowers than the dwarfer and more compact, so the beginner should bear this in mind and see that a good proportion of the smaller plants are potted off, otherwise he may have a larger percentage of singles than is usual. The earlier the seedlings have a separate existence the better, and care must be taken to prevent them becoming starved in the 3in. pots. Directly they have made a reasonable quantity of roots, they must be transferred to their flowering receptacles, *viz.*, 5in., 6in. or 7in. pots, according to the strength of the plant. Good drainage is essential and the rooting medium consists of fibrous loam three parts and one part leaf-mould, to which is added a 6in. potful of old mortar rubble to every bushel of the mixture. If the loam is rather poor quality, a half teaspoonful of bone meal may be sprinkled over the rough material in each pot, at the final potting. This will prove beneficial just when the plants are pushing up their flower spikes. Cool treatment throughout is the keynote of success, and the plants can be kept in an airy frame until there is any likelihood of of frosts getting in. Then a light shelf in the greenhouse should be chosen, till they approach the flowering stage. When the flower spikes are visible and the pots are filled with roots, they may be fed once each week with weak liquid manure, or some approved fertiliser, but be careful to carry out the directions of the makers.—T. W.

Pot Your Nerine Bulbs Now.

THESE beautiful bulbous plants are specially suitable for the amateur's greenhouse, for they require no special treatment and can be grown in any ordinary greenhouse where a temperature of 50° is maintained, and this heat is only necessary for a short time.

Nerine is a showy plant having immense trusses of brilliant scarlet flowers on stems of about 18ins. to 20ins. high. Readers who contemplate growing a few bulbs should lose no time in potting them up as soon as they can be secured. As they require but little pot space, several bulbs should be placed close together in a good size pot—pots 6in. or 7ins. will grow three or four bulbs quite well. The compost used should be made up of light sandy soil two parts, leaf-mould one part and a good sprinkling of sharp sand. Pot moderately firm, but before potting a good supply of cinders and crocks should be put into the pots for drainage; also in potting allow ample space at the top of the pots for watering. After potting place the plants on a shelf in a cool greenhouse. Here they should stay until the plants are well established and begin to show active growth, when temperature and ventilation must be attended to. The temperature at this stage should be between 45° and 50° at night. Until the plants are established the surface of the soil should be kept nicely moist, but as leaves form and the plant makes growth more water must be given until the flower-buds appear and gradually reduced until the flower dies down, when watering must cease. When the flowering period is over remove the plants to a dry, sunny place where they may be given a period of rest before repotting. These plants should not be disturbed very often, but where it becomes necessary it should be done after the resting period. In repotting care should be taken to remove soil and bulbs intact, and for this shift a little charcoal should be added to the compost. Pot firmly, and keep the plants fairly close until established, when the same cool treatment may be given them. Propagation is best done by off-sets.

The Treatment of Pelargoniums.

PELARGONIUMS and some of the finer kinds of geraniums may be propagated in August. If treated early, they may be better established before winter than if taken late in the season.

There is no definite method of inserting the cuttings. They may be simply dibbled into a border, or flower pot, fully exposed to the sun. Before the approach of the autumn frosts, the cuttings may be lifted and potted, or planted in boxes and placed in a cold frame. Of course, the cuttings may be put into pots or boxes at once. The soil should contain a goodly proportion of fine sharp sand. A little well decayed turf, well mixed with the potting soil, helps to enrich it. The soil should be made moderately firm. The cuttings will hardly take root if the soil is too loose or too dry. After the cuttings are inserted, give them a good soaking of water and stand them in a sunny place on a bed of ashes.

When taking cuttings thus early, it is well to take the first batch from those plants that are overgrowing the edges, so as not to disfigure the beds.

Tricolour geraniums and similar varieties may receive attention first, the zonal and other strong-growing ones being left for later treatment.

If there are heavy rains, the cuttings may be placed in a frame; or be covered with a sash or hand-lights; but in fine weather they are better in the open air.

If a goodly number of cuttings is wanted, propagation should be started as soon as possible, as a greater number can thus be secured.—J. W.

A Climber for the Greenhouse.

A WORTHY companion climber to Plumbago capensis for the cool greenhouse is the beautiful Abutilon Milleri. This plant will flourish under exactly the same conditions as the plumbago, but flowers during the early summer and remains in good condition for a long period. If both plants are grown, a continuity of bloom is ensured for the greater part of the year. Abutilon Milleri possesses the additional attraction of having prettily variegated foliage, which remains in good condition throughout the year. It is on the slender shoots of the previous year's growth that the flowers are borne. These shoots should be allowed to hang down from the main stems, and during the flowering season each will be festooned with bloom. The individual flowers are 1½ins. in diameter, bell-shaped and of a rich orange-amber colour with a dark maroon blotch on the inside of each petal at the base. The russet-coloured calyx surrounds the lower portion of the five petals, and the flower depends from the shoot on which it is borne on a slender stalk about 1½ins. in length. Each leaf is not unlike that of a maple, but much longer in proportion to its breadth. Of a deep green hue, the foliage is blotched with pale green and yellow.

Specimens may be successfully cultivated in pots, or they may be planted out in a border, the latter being perhaps the best if they are required to cover a fairly large area of roof space. The pots or border must be well drained, and a porous compost consisting of good fibrous loam, leaf-mould, sand and a little bone meal must be provided. Keep the plant reasonably moist at all times of the year and feed established specimens with dilute soot water and manure water when they are growing freely.

Propagation may be readily effected by means of cuttings of the young growth inserted in pots of sandy soil and placed under a bell-glass in the greenhouse and kept shaded from the rays of the sun until roots are emitted. After flowering thin the shoots out as may be necessary, retaining sufficient to provide a good display of bloom the following year.—T. H.

Ornamental Asparagus.

MOST of the decorative forms of asparagus are of simple culture, providing attention is given to a few points. One important feature is to see that the pots are especially well drained, as anything like a waterlogged soil is certain to bring about a wholesale dropping of the leaves. Plenty of water is required during the growing season, especially if the plants are in a warm house. When the asparagus is treated as a greenhouse subject a good deal less moisture will be needed, and, in all cases, this should be much reduced during the winter, when the evergreen kinds are largely at rest. The best soil for ornamental asparagus is that formed of equal parts of loam and leaf-mould to which a rather liberal amount of sand has been added. Propagation is by seed sown in brisk heat as soon as they are ripe, by layers in the summer, or by root division when the plants are at rest. Some of the decorative asparagi form excellent basket plants, and of these retrofractus and Sprengeri are the best. The popular smilax (Asparagus medeoloides) is largely grown by training its long shoots to strings running from the floor to the roof of the house. The shoots, as desired for use, may be cut close to the ground, and this encourages the tuberous roots to throw up others. Another climbing species is A. plumosus with several important varieties, one of which, nanus, is dwarf in habit. All the ornamental species of asparagus much appreciate regular syringings during the summer. Weak liquid cow manure mixed with soot water encourages a vigorous growth. The chief insect pest is mealy bug, and for this a sharp look-out should be kept. If once the pest secures a hold there is nothing to be done, in most cases, save to cut the plants back, as insecticides will not completely penetrate the dense foliage.—L. B.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints (which should not exceed 150 words in length) is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

When Lettuces Bolt.

Most gardeners, sooner or later, are faced with the problem of what to do with a batch of lettuces which have prematurely gone to seed. Usually they are either fed to the fowls or relegated to the "Adco" heap. Both admirable ways of getting rid of them, but there is a better—cook them. It is not at all commonly known how good the leaves of lettuce are when cooked like spinach. They should stew very slowly, but personally I boil them in just sufficient water to prevent them catching, strain off in a colander, press all the water out as far as possible and return to the saucepan in which they were boiled, add a nice piece of margarine and a little pepper, and heat for a few moments. Do not forget to add a few crystals of washing soda to retain the bright green colour. Do not take any of the stalks, just strip off the leaves as you would for spinach.—E. C.

Dividing Flag Irises.

It will soon be time to divide or replant flag irises. For those who purchased plants last autumn or early this year and whose garden expenditure is limited and who wish to increase their stock of, say, two dozen varieties, the following method which I have successfully followed is a good one. By this way an iris garden can quickly be filled. Dig up the clumps and cut off all the clean new shoots with an old kitchen knife, taking about 2ins. of rhizome for each new plant. Plant firmly in new positions, clipping off about 4ins. of the "grass" with a pair of sharp scissors. Plant the old clumps in an odd corner. Next year they will send up a large number of fresh shoots. These can be treated in the same way as this year's growth, so that by the third year after purchasing the plants, the iris garden will be well filled, and in May and June it should be a mass of bloom.—M. H.

A Kneeling Pad.

A useful kneeling board which acts as a preventive of rheumatism can be made in the following manner: Take an old box about 14ins. long and 6ins. deep. Remove one of the wider sides. Place 2ins. of thick horse-hair or any other stuffing on the bottom to act as a pad on which to kneel. Cover with a strip of an old mackintosh or other waterproof material the width of the box but a yard or more in length. The piece over is for the legs and feet to rest on when kneeling, so as to keep them off the ground. If a strip is nailed round the outside with a pleat at each corner and left open at the top it makes three useful pockets for seeds, labels, handfork, trowel, etc.—Q.

A Good Way of Propagating Violas.

Those who want to increase from their own plants and do not possess a frame in which to take autumn cuttings, and who dislike the straggly plants that result from dividing up a plant, will find the following a simple and good plan. Take up, now, the plants from which you wish to propagate, plant them in a reserve border, and cut them back hard. Then earth up the soil on each side till they are nearly covered, and as the young shoots grow up through the soil a further earthing can be given. Dig up the plants in September and you will find each consists of a number of strong young rooted plantlets which can be separated and planted out, and which make good, compact-growing plants.—V. W.

Mulching Crops.

The placing of a mulch on the soil near growing crops of beans of all kinds, peas and onions is time well spent. Early mulching is more beneficial than if it be left until the crop appears to be suffering before even a heavy mulch is applied. The best time is to put on the material directly a heavy shower of rain has fallen. It is wonderful how long the soil then retains the moisture. Half-rotted manure forms the best mulch, but lawn grass may be freely used in the case of peas and beans.—J. P.

Damaged Conifers.

It sometimes happens that the top of a conifer gets accidentally broken out, thus spoiling the future shape of the tree. A simple plan to follow, and one which I have tried successfully, is to make a clean cut through the tree below the break. Then cut off the tips of the surrounding branches. The tipping causes an extra flow of sap to the top of the tree, resulting in a strong break which grows straight up. In a short time this lead growing stronger than the branches makes a new top, completely covering the cut portion, and brings back to its shape an otherwise spoilt tree.—J. N.

A Garden Scrap-Book.

Procure an old foolscap exercise book. Number the pages. Divide the book up into alphabetical portions, taking just over half the book for this purpose. Use the other half by dividing it into twelve monthly portions. Both THE GARDEN and *Homes and Gardens* have a number of paragraphs which are of particular interest to an individual, whereas the remainder is of general interest. Personally, when I have thoroughly read both papers, I again go through them and cut out items which particularly interest and concern me in my garden. I then paste them alphabetically into my scrap-book. I also extract the month's work and paste it into the monthly portion. In addition I retain any pictures of garden formations which may come in handy at a later date. This scrap-book forms a real ready reference, as it only includes those items which I personally require, and it has soon become "my own garden manual."—L. G. B.

OUR SERVICE BUREAU

Chrysanthemum Pests.

Could you tell me the cause of the marking on chrysanthemum leaves enclosed. It occurs on plants both in the greenhouse and outside.—E. P., Kingston Hill.

Your chrysanthemum leaves are infested with the leaf-mining maggot. The fly deposits its eggs in the leaves and the resultant grubs eat them as shown. Pick off and burn badly affected leaves. Syringe the foliage weekly with weak doses of clear soot water and scatter dry soot about the pots weekly to keep the fly away from that quarter.

Rose Leaf Trouble.

I enclose some defective leaves from one of my rose trees. I shall be glad of information as to its cause and remedial treatment required. It occurs a good deal in one particular bed of Harry Kirk roses. Also, can you tell me the cause of so many of my cucumbers becoming curled upon themselves in the frame, almost horse-shoe shaped.—H. C., Fleetwood.

The rose leaves are eaten by small caterpillars, a result of a long spell of dry weather. The recent rains will have cleared the trees considerably, but you should syringe with "Abol" directly you find any more leaves eaten. It is the cold—especially at night—that causes your cucumbers to curl instead of growing straight. Heap litter, grass from lawns and similar material round the frame, also cover with mats at night; remove the latter from the glass early the next morning to admit light.

Diseased Azalea Leaves.

Can you advise me on these diseased leaves of Azalea Hexe. The plant is in loam and leaf-mould only and has a mulch of cow manure and up till two days ago was apparently healthy. It is grown in the open in a half-shaded position. I have picked off all diseased leaves.—J. C., Totnes.

The azalea leaves sent for our examination are attacked by the fungus Exobasidium japonicum. Remove the galls before the white bloom (*i.e.*, the spores) is developed. If the removal of all infected leaves is done thoroughly there should be little trouble from this disease in the future. Mulching the attacked plants is helpful, but you should not use a too strong manure, *e.g.*, cow manure.

Keeping Geraniums Through the Winter.

Is it possible to preserve geraniums through the winter in a frame with no heat?—F. P., Harrogate.

During a mild winter geraniums can be kept in fairly good condition in a garden frame. Dry litter, bags or mats for covering will be necessary, also the removal of some of the large leaves at the beginning, the removal of any decaying leaves, fresh air in open weather, and dryness at the roots, with a fairly dry atmosphere.

Preserving Copper Beech Leaves.

How can I preserve copper beech (small branches about 18ins. long) without the leaves being either disfigured or withered, so that I can use them for church decoration at Christmas? Do the branches have to be taken from the tree at a certain period? I have tried one or two ways to preserve them, but have not been successful so far.—J. D., Burley-in-Wharfedale.

The copper beech leaves should be gathered when matured—just as the flowering stage is reached, before nuts form on the leaves. Press them between large sheets of blotting paper for several days to absorb some moisture, then suspend in a cupboard or large box in a shed. Place a vessel containing muriatic acid and sulphur in the box and make the latter airtight. Keep in the box for about twenty-four hours.

Treatment of Cyclamen.

Can you tell me how to treat cyclamen seed? I have several lots of both autumn and spring flowering varieties in my garden, and they all bear lots of seed pods.—A. C., Bishop's Stortford.

Leave the seeds on the cyclamen plants until quite ripe, when the pods come away easily. Gather and dry off in a cardboard box. Sow in sandy soil in pots, or in rows in a cold frame.

BULBS & LAWNS

Carters new season's Catalogue, "Bulbs and Lawns," just published contains a special section devoted to those varieties suitable for early forcing and indoor cultivation. Flowers are specially welcome at Christmas and Easter, and to ensure a display of bloom at this period, varieties such as Extra Early Miniature Hyacinths, White Roman Hyacinths, Duc Van Thol Tulips, and Lilium longiflorum should be procured immediately. Our new Catalogue, "Bulbs and Lawns," gives full particulars of these varieties and end-of-season renovation of lawns, post free on application.

THE GARDEN

VOL. XCI.—No. 2907. AUGUST 20, 1927. PRICE TWOPENCE.

PLANTS FROM ROOT CUTTINGS

MOST gardeners know what it is to lift a plant of a herbaceous perennial, like the Japanese anemone, apparently removing every portion, and yet to find the plant still growing in the old place the following year. Here is very good evidence that plants will shoot up from pieces of root left in the ground, and this points to an interesting method of propagation. Quite a number of perennials can be freely increased by means of cuttings made of the thick fleshy roots on which buds have formed. In some cases this is quite the best way of getting an increase, and the plan is always worth trying when other means of propagation prove somewhat difficult.

Speaking generally, root cuttings are best taken after the plants have flowered in the summer and from then onward until the coming of cold weather, or in the spring. One great advantage of taking the root cuttings in the late summer is that well developed specimens are secured by the following year. In all cases, however, one should wait until the flowering of the plant is over. Now and again sufficient roots for the purpose can be secured by digging round the plant. In others it is better to lift the plant and shake the roots free from soil, cutting all the thicker roots away and only leaving the parent plant with enough growth to start away again when replanted. Three inches is a good average length for a cutting if plenty of roots are to be had; but pieces a good deal shorter than this will often give quite good results. The roots of anchusa, crambe, anemone and others will grow if set about 2ins. down in beds of sandy soil out of doors. It is better, however, to start them into growth in a cold frame or greenhouse if this is possible. Boxes of flowerpots 4ins. to 6ins. deep should be given plenty of drainage and then filled with a compost formed of equal parts of loam, leaf-mould and sand. Long pieces of root may be inserted in the soil by making a vertical hole with a pointed stick rather thicker than the root. The top of the root should be just below the surface of the soil. Small sections of root can be covered with a layer of the compost. The subsequent treatment of the young plants, which come after the development of the buds on the roots, depends on the convenience of the grower. It should be noted that the specimens are brought on to a good size much more rapidly if they can be potted off singly and given two or three months in a cold frame before being placed in the open border.

Plants which give good results if propagated by means of root cuttings are numerous, but special mention may be made of the following: The thick fleshy roots of the Dropmore and other alkanets (anchusa) are excellent subjects for propagation by means of root cuttings. Pieces of root about the size of the little finger are used, and these develop shoots with great vigour. Most hardy perennials belonging to the same family are readily increased by means of root cuttings. Calystegia and convolvulus grow very freely from pieces of root, and even the tiniest fragments will develop into plants.

Mention has already been made of the flowering seakale (crambe), which has large fleshy roots that, if cut up into pieces, will grow almost as freely as the common seakale. Fraxinella (dictamnus) can also be freely propagated from roots; and the same is true of hemerocallis (day lily). If the thick fleshy roots of incarvillea are cut up and placed in sandy soil, they will rapidly develop into plants. The giant bell-flower (Ostrowskia magnifica), with its long root, like a huge carrot, is not an easy subject to transplant, yet, curiously, quite small pieces of root nearly always grow, even though the parent dies. Many gardeners know that peonies may be propagated by means of root cuttings, and the same is true of the Oriental poppies, the white Californian poppy (romneya), Senecio pulcher, and the symphytums. Of course, this does not by any means exhaust the list of subjects which can be propagated in the manner under consideration, and there is room for experimenting in this direction. It is a job that all amateurs should try, as in nine cases out of ten success is almost certain, and it is a method which should be practised in cases where it is desired to increase the stock of any particular plant which responds to this treatment.

Bulb Planting Time.

READERS will note in this issue several pages are devoted to bulbs and their cultivation. It is the beginning of the bulb season, and as early preparation means early planting and in turn early flowering, readers should make a point of making out their bulb order within the next two or three weeks with the arrival of the various bulb catalogues. There are plenty of subjects from which to choose, and the planting of daffodils, snowdrops, crocuses, chionodoxas and scillas can all be carried out next month in the open; while hyacinths, freesias, early-flowering narcissi, etc., may be placed in their pots for an early display in the greenhouse.

This Week's Work

For Gardens in the South and Midlands.

Pot up Roman hyacinths and freesias.

Take cuttings of violas, pentstemons and geraniums.

Take chrysanthemum buds.

Cut back herbaceous plants that have finished flowering. Keep the border hoed regularly.

Stake gladioli and clip evergreen hedges.

Sow schizanthus in pots and place on a shelf in the greenhouse.

Make another sowing of spring cabbage and earth up celery.

Pot on young primulas, cyclamen and zonal pelargoniums.

Plant out winter greens.

This Week's Work

For Gardens in Scotland and the North.

Take cuttings of petunias, salvias and verbenas.

Pot up Paper White narcissi.

Begin planting snowdrops.

Pinch out side growths of late-flowering chrysanthemums.

Top gooseberry shoots for American mildew.

Trap wasps and earwigs.

Sow cyclamen and give shade until germination has taken place.

Discontinue feeding roses.

Lift mid-season potatoes.

Continue to earth up celery.

Cut out old wood of loganberries after fruit is gathered.

Complete summer pruning of apples.

Digitized by Google

DAFFODILS TO BE NOTED AND GROWN

THE Editor has asked me to give a list of the best daffodils for general cultivation arranged under their various sections. I fear this will much resemble a catalogue, but do not see how to avoid the same. I do not intend to name the oldest and best known things, such as Emperor, Empress, Horsfieldii, etc., as these are in every trade list. Also the very expensive varieties will be avoided, as seekers after these are very "few and far between."

TRUMPETS.

To take the trumpet varieties first.

Yellows.—King Alfred, a glorious golden yellow flower, perfectly balanced and most satisfying in every way but one, *i.e.*, it will not grow well with everyone, even where other daffodils thrive to perfection. Van Waveren's Giant, a huge fellow with golden yellow trumpet and segments of much lighter yellow. Tresserve, a bright yellow daffodil of largest size but not coarse. Buxted, a finely built flower of the Emperor type, a much improved Lord Roberts. Golden Emperor, an improved King Alfred, and will grow where that variety will not. General Townshend, a very perfect flower on the lines of Lord Roberts. Potentate, a very bright yellow of large size, very robust in growth and very free—eleven blooms have been counted on one bulb—early flowering; a very fine garden plant. Lemon Giant, a large flower with lemon-yellow trumpet and palest yellow segments, very distinct. Dawson City, a fine exhibition variety, but still rather expensive.

Bicolors.—Spring Glory and Glory of Noordwijk, very much alike and both improvements upon the older things, such as Empress and Horsfieldii. Florence Pearson, a pale bicolor of very strong constitution and extra good for pots. Weardale Perfection, a large and late pale bicolor. Phantasy, a very beautiful flower borne on long stalk, comes quite white under glass. Moira O'Neill, a pale bicolor of great value as a show flower, as well as being a good garden plant. Vestan a very fine late flower in the way of Weardale. Lady Mine, a medium-sized flower of perfect shape and extremely free flowering.

White Trumpets.—These are not yet common. The best are White Knight, Mrs. R. Sydenham and Beersheba, the finest of all, but still expensive. Mme. de Graaff used to be classed as a white, but is now under the bicolor section. Cut young and opened indoors it comes quite white.

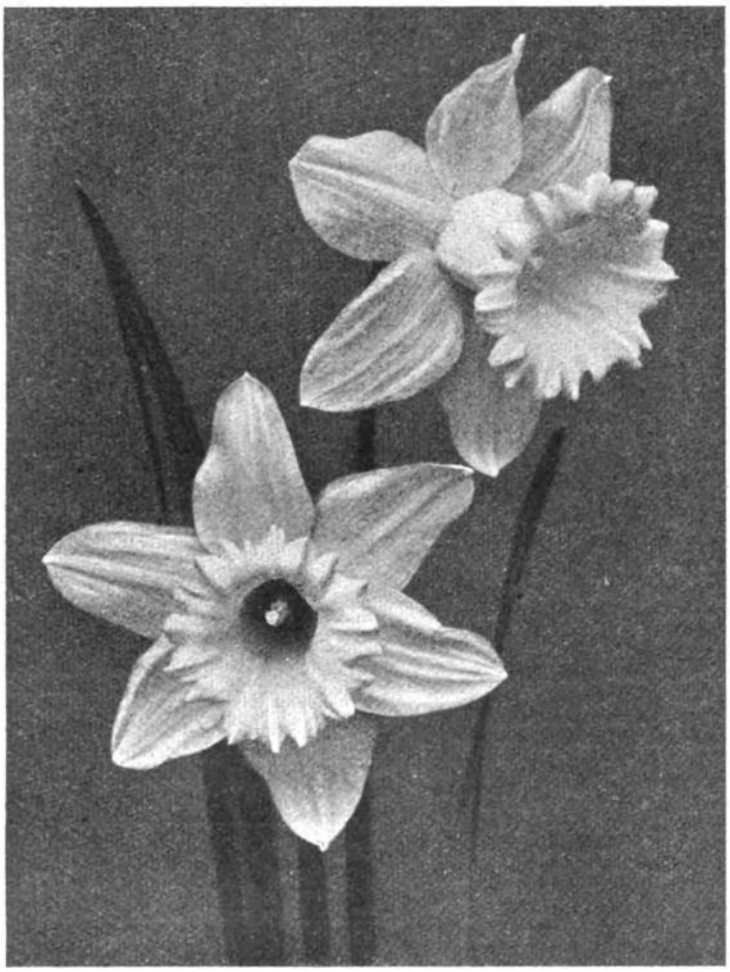
INCOMPARABILIS.

The giants of the Incomparabilis section have long cups nearly as long as trumpets. Lucinius is an all-yellow flower of perfect shape, a fine show variety. Noble has a pale yellow perianth and deeper yellow cup, a good sturdy plant. Great Warley, a very large bicolor. Steadfast, another bicolor, very late flowering, almost coinciding with the Poeticus section. Kwasind, a large all-yellow flower with slightly twisted segments. Golden Pedestal, a very fine golden yellow variety, very vigorous and free, at present high in price.

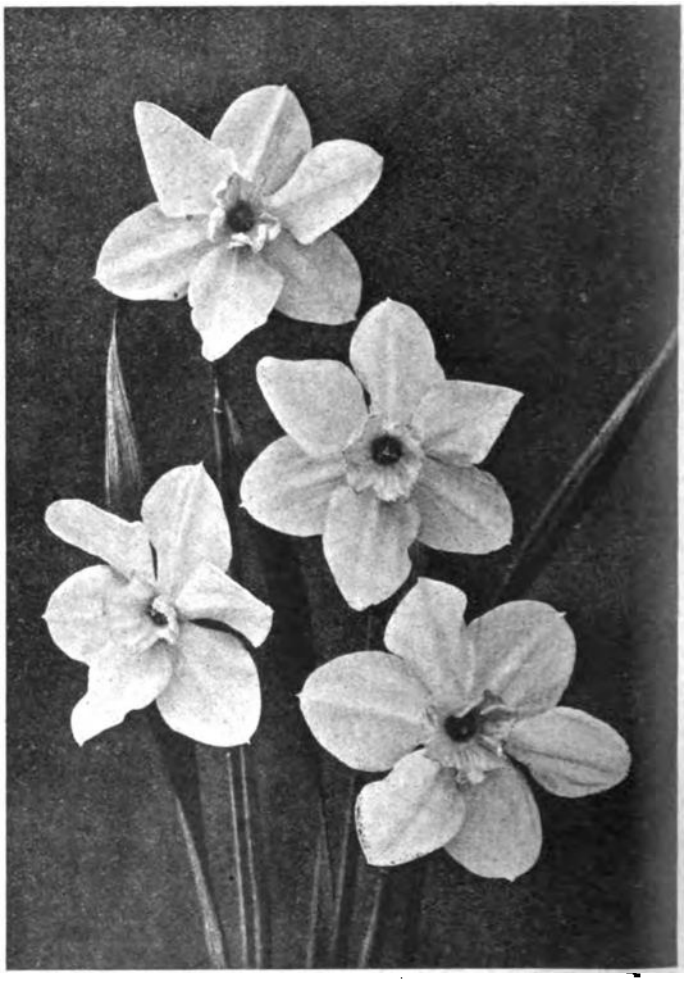
Small Incomparabilis.—Lucifer, segment white and rather narrow cup, bright orange, very good for cutting or for pots or bowls. The Star, an early rather pale yellow flower. Plant very healthy and vigorous. Bernardino, a flower of great refinement and beauty. Segments creamy white, the large cup is tinted with apricot, which colouring varies with soil and seasons. Macebearer, a good round flower with creamy white perianth, cup yellow edged orange; long stalk and ample dark green foliage. Marshlight, a much improved Lucifer, the cup is often almost crimson; rather scarce at the present time.

BARRII.

Daffodils in this section have shorter cups than the Incomparabilis. Firebrand, a small flower with creamy white segments and a cup of fiery red. Conspicuus, an old variety, but still holding its own in public favour. Lady Moore, white well rounded perianth, cup yellow edged orange. Very good in pots. Brilliancy, yellow perianth and cup with bright orange-red edge. Very early and a great one to increase. Firetail, very large flowers of fine form, with deep red eye, very late. Nursemaid, very like Firetail and less expensive.



KING ALFRED, A HANDSOME DAFFODIL, WITH CLEAR LUMINOUS YELLOW TRUMPET BLOOMS.



EVANGELINE, AN EFFECTIVE AND STRONG-GROWING LEEDSII VARIETY.

Digitized by Google

LEEDSII.

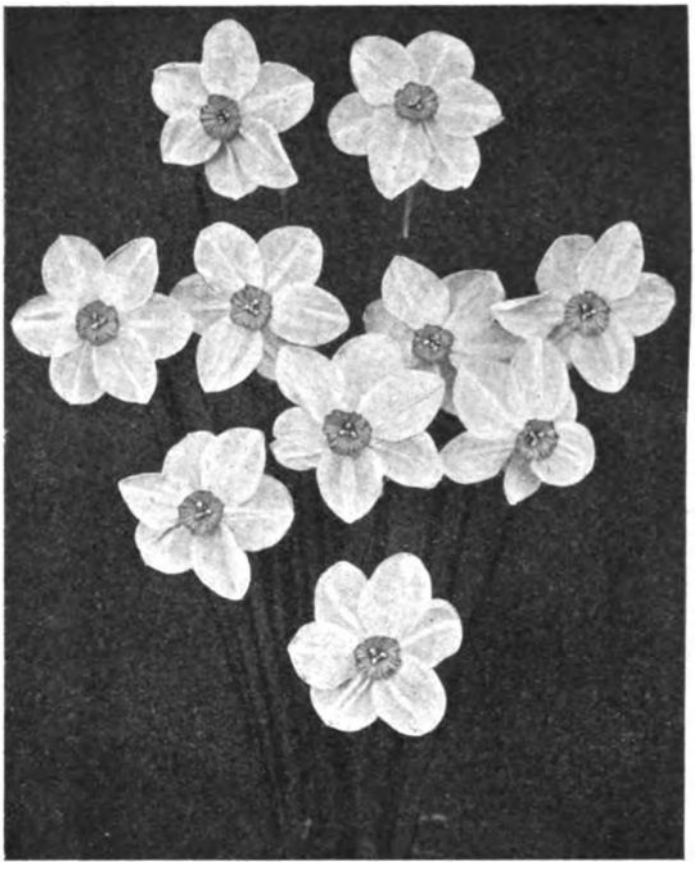
These have the same proportions as the Incomparabilis, but in coloration they are quite distinct. The cups are generally pale yellow, sometimes passing to white, but they may be tinted with apricot, and in very few cases pink! One of these named Mrs. R. O. Backhouse sold a few years ago at £50 per bulb, and is even now £10 to £12.

Giant Leedsii.—Empire, pale yellow cup and white perianth, a large and well formed flower, very free flowering. Hon. Mrs. Frecklin, pale yellow cup, white segments, a perfectly formed flat flower of lasting quality. Sanctity, a drooping flower of almost trumpet proportions, a chastely beautiful variety. Puritan Maiden, a lovely flower of show quality, very nearly a trumpet variety. Mitylene, large white flower with wide cup, pale primrose, passing to white, very distinct. Hymettus, large pure white perianth, cup long and recurved at brim. Tenedos, perhaps the finest of this section. The last four varieties are all rare and expensive.

Small Leedsii.—These are all white with pale yellow cups. Fairy Queen, small, but very dainty. White Lady, a strong grower, flowering late. Evangeline, very free flowering. St. Ilario, very late. Hera, a large flower, nearly large enough to be classed with the giants. An all-white flower of great beauty, late.

HYBRIDS.

Triandrus Hybrids.—These are all the result of crossing the beautiful little Triandrus albus (species) with garden varieties. Many beautiful things come from this cross, but they are nearly all delicate, and nothing but a well chosen spot in a rock garden will satisfy their needs.



FIRETAIL HAS A CUP OF THE DEEPEST FIERY RED.
It is one of the best of the Barrii varieties.

Cyclamineus Hybrids.—Again a cross between a wilding and cultivated varieties. Orange Glory, February Gold and March Sunshine are the best I know. They are well suited for rock gardens.

Jonquils and Jonquil Hybrids.—The jonquils have small all-yellow flowers. Generally there are two flowers on a stalk, sometimes three. Of the hybrids the best I know of is Buttercup, a large deep yellow.

POLYANTHUS AND POETAZ.

These are the bunch-flowered narcissi, some having as many as ten flowers on one stem. The Poetaz section is the result of a cross between the old polyanthus narcissus and the Poeticus. Some of the best of the Poetaz are Alsace, Elvira, Admiration and Laureus Koster.

PORTICUS.

These daffodils are all late flowering. There is now a great number of varieties on the market. It is quite as important that the plant should be a good doer as that it should bear a good flower. The following I have found the most satisfactory all-round varieties: Homer, early and good for pots. Horace, a tall and strong grower. Jean Ingelow and Rupert Brooke, both plants of exceptional vigour.

DOUBLES.

Doubles.—These do not appeal to the writer, but find many admirers among the general public. Argent and The Pearl are good and cheap. Twink, Royal Sovereign and Mary Copeland are fine but dear.

This is only a selection from some 3,000 named daffodils, and many good things are no doubt omitted. On the other hand, nearly every variety mentioned has come under my personal care.—J. DUNCAN PEARSON

NOVEL WAYS OF GROWING BULBS

INDOOR bulb growing is a very fascinating form of room gardening in which everyone can engage. Providing one secures the right kinds and varieties (a point on which any of the well known firms are glad to advise), all the ordinary spring flowering bulbs are extremely easy to grow. Generally speaking, for the room culture of bulbs it is better to use the fibre which is sold specially for the purpose. This is clean to handle and there is no need to bother about the question of drainage as is the case where soil is employed. Anything that will hold the fibre will do well, and it is often possible to find odd vessels, like ginger jars, broken bowls, old baskets, etc., which answer the purpose. A very attractive way of growing the bulbs is to plant them in large shells. At second-hand shops it is usually an easy matter to pick up some of the large tropical shells for quite a small sum. Choose those that have as much room inside as possible. Naturally, with the smaller shells, crocuses, scillas, etc., will be best; but in the case of the big ones some fine effects are secured with hyacinths, narcissi and tulips. Have as deep a layer of fibre as possible on the bottom before setting out the bulbs, and then, after planting, pack in more until the shell is full. Of course, the bulbs must be given a spell in some dark or well shaded place, so as to encourage a good root development before the shoots are encouraged to develop in the light. A pretty effect is secured by covering the fibre with moss or by sowing grass seed on the surface a few weeks before the bulbs are likely to come into flower.

A LARGE POT IN WHICH HOLES HAVE BEEN BORED MAKES A NOVEL BULB GARDEN.

Bulb-growing in a sponge is another interesting way to try. Here one should obtain a sponge of good size that is of a fairly rounded shape. Loop string or, better still, copper wire round the sponge so that it can be suspended. The bulbs are inserted in the holes

AN ATTRACTIVE WAY OF GROWING BULBS IS TO PLANT THEM IN A LARGE SHELL.

Digitized by Google

of the sponge, or, if these should not be big enough, they may be somewhat enlarged with a little cutting. It is best to plant the sponge when it is quite dry, as the bulbs are then held more firmly in position. For culture in sponges any of the smaller varieties of hyacinth sold for early flowering are suitable. Crocuses and Paper White narcissi also do well, although in the latter case rather a big sponge will be needed. For some reason tulips are not much of a success in sponges, and it is hardly worth trying these. After the insertion of the bulbs the sponge is soaked in water and is then suspended in some dark place until rooting has taken place. Then a position in a light sunny room is admirable. All along, of course, the sponge must be kept moist and in a warm apartment; it is likely that a daily soaking in water will be required. Bright green moss may finally be tied round the sponge, and if thin twine is used this will not be noticed at all. Another way is to sow grass seed on the sponge. To make the seed adhere let the sponge be in a thoroughly moist condition and then press the seed thickly on to the surface with the fingers, and by the time the bulbs are in flower the sponge is completely hidden by the greenery. The grass seed should be sown just when the flower buds begin to put in an appearance.

A rather novel bulb garden in a pot is shown in the first illustration. Here a large pot was secured, and round this, at intervals, holes were bored. These openings were about 2ins. across and were separated from each other by rather more than this distance. The holes in the pot were easily worked out by means of an augur and an old "bit," the final enlargement being obtained with the help of a cold chisel. Those who do not want to do the job for themselves will find that a stone-mason would bore the holes for a small charge. As the pot is filled with fibre the bulbs are inserted so that the crowns face out of the holes. In the upper part of the pot bulbs may also be planted, and, when flowering time comes, the effect is very striking. Crocuses and scillas grow very well in the pot garden, and on account of their cheapness they may be planted thickly, to give a massed effect. The planted pot must be given a spell in some dark place to encourage rooting. Afterwards, when the pot is brought into a room, it should be turned daily so that all sides receive an equal amount of light.

A pleasing table decoration is secured by arranging some floating bulb gardens. These are formed in the following manner: Secure some pieces of cork—these might be large flat corks of a regular shape, or just odd fragments of virgin cork. Each cork is to form one floating garden of which there might be two or three in a large bowl. In these floating gardens it is best to employ the smaller bulbs, like crocuses or scillas and holes are bored in the corks so that the bulbs may be accommodated. It should be arranged so that the under part of each bulb is just in contact with the water when the corks are floating. Choose a large bowl which will give quite 2ins. or 3ins. of depth when it has water in it. In the water it is a good plan to place one or two lumps of charcoal. If this is not done the water should be changed every ten days. It is a great advantage to use rain-water or at least tap water which has been exposed to the air and sun for a few days. Let the bowl have a spell in a dark or at least a well shaded place until the roots are being sent down freely by the bulbs. Then a position in a sunny window is the best, when the bulbs soon come into flower. The corks may be hidden with fresh moss or grass seed may be sown soon after the bowl is brought into the light. When these floating bulb gardens are in full beauty a very charming effect indeed is secured, and the whole thing makes an interesting centre-piece for a table. L. B.

DWARF TULIPS FOR THE ROCKERY

THE numerous species of tulip display great diversity of size, form and colour, and the "miniatures," of which there are several, are particularly interesting and well adapted for growing on the rock garden, and they are not too obtrusive for even the smallest representation of this popular phase of gardening. They possess, in great part, brilliant colouring, in lively and pleasing contrast to the soft tones usually associated with vernal flowers. With few exceptions they are easily managed in well drained soil in sunny positions on the rock garden or in the border, and the majority of species are sufficiently sturdy to withstand the vagaries of an English spring.

The bulbs should be lifted annually and stored in a dry place until autumn. This is a rather tedious operation and may not, in some instances, be absolutely essential, but I certainly believe that many choice bulbs have been lost through inattention to this detail. Lifting should not be practised until the foliage has "yellowed" or withered.

One of the daintiest little tulips for a sunny border is T. dasystemon, which only rises some 3ins. or 4ins. from the ground. The buds are green with some brownish shading, and the open flower is white with a golden "sunset" base, and three, four or even six flowers are produced from one bulb in April, in some seasons a little earlier.

T. linifolia from Persia forms an almost prostrate rosette of small leaves, and the flower is of the most brilliant sealing-wax red with a glistening black base. Very near to linifolia is T. Maximowiczii, with flowers of the same brilliant hue, but the plant is of rather earlier growth and possesses stem leaves as opposed to T. linifolia. A colony of half a dozen bulbs or so will be noteworthy in late March and April.

T. Batalini is a plant of dwarf stature with soft yellow flowers, one of the prettiest and one of the very best, as it is one of the most easily amenable of rock garden bulbs. T. Clusiana, the well known "lady tulip," is of slender growth and of graceful port, the small, somewhat pointed flowers white flushed with red on the outside and with a purplish black base being singularly attractive. Usually in flower during April, this dainty species has for long been known in British gardens, for it was introduced from Southern Europe so long ago as 1636. T. persica (syn. Breyniana) is a pretty little plant, one of the smallest of tulips, with bronzy yellow flowers. It grows and increases freely, and is ideal for the rock garden or bulb border. It may, if so desired, be utilised as an edging for the latter.

T. KAUFMANNIANA, THE WATER-LILY TULIP, IS THE FINEST OF ALL SPECIES FOR THE ROCK GARDEN.

T. pulchella from Asiatic Turkey is a somewhat variable species, usually rosy crimson or carmine crimson in colour. It is a dainty flower of dwarf stature, enjoying a warm nook, as does T. primulina, with white, sometimes pale primrose and lilac flowers and conspicuous yellow anthers. About 9ins. in height, T. primulina is indigenous to Algeria.

Perhaps the finest of all tulips for the rock garden is the water-lily tulip, T. Kaufmanniana, in its varied forms. Some flowers are white with a golden centre, some white flushed red, others almost wholly red or yellow, and as still another variation, one very fine variety is white and golden centred, the outside of the perianth apple green. The glorious golden base, a marvel of colouring and reminiscent of the setting sun, is, however, always present, and a fully open flower, like unto a great water lily, is indeed lovely. A curious character attaching to this species is that the flower-buds are coloured from their conception and not green as in the familiar Dutch and Darwin tulips.

Such magnificent tulips as Greigii, Eichleri, Fosteriana and præstans I have not hitherto mentioned, for their proportions are as magnificent as their colouring, and while quite "at home" on the rock garden of generous dimensions, they are not so suitable for one of less pretension, and I particularly wish to focus attention upon those species of lowly stature and rare beauty. These bulbs will not be planted until early autumn, during the period September–November, but I most strongly advise the enthusiast to institute early enquiries for these bulbous gems. Stocks are much depleted, and considerable search and correspondence may be entailed before possession is secured. R. E. A.

BULBS FOR CUT FLOWERS IN SPRING

A List of Suitable Varieties which are Decorative yet Inexpensive

UNLESS one has a very well filled purse, bulbs grown solely to supply cut flowers cannot be of the newer and more expensive kinds, but there are plenty of older and cheaper ones which are quite good enough for the purpose. Here, for example, is a list of a dozen very moderately priced narcissi which will provide a succession of beautiful flowers throughout the spring. Golden Spur, Henry Irving, Emperor, Empress and Mme. de Graaff, all trumpets; Lucifer, Cynosus, Sir Watkin and Frank Miles of the incomparabilis section; Mrs. Langtry and White Lady of the Leedsii division; and the well known Barrii conspicuus. To these may be added the Campanelle jonquil (N. odorus Campanelle), the double N. incomparabilis Golden Rose (an improved "Butter and Eggs") and the old Pheasant's Eye, which takes long to establish, but once settled down will increase year by year.

Single early tulips are more attractive in the cut state than are the doubles and a good and cheap half dozen would be the following: Prince of Austria, Rose Misante, Yellow Prince (fragrant), Thomas Moore Improved, Crimson King and White Swan. All the May-flowering tulips are charming for room and table decoration and a mixture of the Darwin and Cottage types will give excellent results at small cost. However, should it be preferred to buy named varieties, these will be found a good selection, although none is a recent introduction by any means: *Darwin*.—Clara Butt, Etguste, Farncombe Sanders, Rev. H. Ewbank, La Marveille, Flambeau. *Cottage*.—Golden Crown, Moonlight and Inglescombe Pink, Picotee, and Inglescombe Scarlet. The gorgeous Parrot tulips are too "floppy" to be suitable when cut for anything but a hanging basket, but the Rembrandt and Old English tulips, so quaintly flamed, blotched and feathered are beautiful arranged in big groups in jars or bowls of some deep plain colour—green, brown, copper or dull blue—but their price is higher than that of the majority of tulips already mentioned in these notes.

SNOWDROPS, WHEN ARRANGED IN LOW BOWLS, ARE EXCELLENT FOR INDOOR DECORATION IN EARLY SPRING.

THE ORNITHOGALUMS ARE USEFUL SUBJECTS FOR CUTTING. *The flowers last a long time, as much as three or four weeks in water. The one shown is O. arabicum which has black centres to the flowers.*

All kinds of irises are to be reckoned among the loveliest of flowers for decorative purposes, of the bulbous type, the February blooming Iris reticulata and its variety Krelageii, are best, perhaps, grown in bowls or pans, but they are very dainty when cut if arranged in slender stemmed vases. At the end of May the hybrid xyphium—sometimes known as Dutch irises—come into bloom to be followed by the Spanish and the English sections, the last named flowering about the end of June. Each of these irises may be planted in mixture satisfactorily and the expense will be far less than if named varieties are chosen. It is said that while Dutch and Spanish irises prefer a light soil, the English do better in a heavy one, but the last mentioned thrive in my garden, the soil of which is exceptionally light.

Possibly some excuse is needed for introducing the winter aconite, Eranthis hyemalis, in this article, as it is a tuber, not a bulb, flowers in winter, not spring, and is not generally regarded as suitable for cutting! But it comes into bloom when the garden is most barren of flowers and its cheerful little golden stars dotted thickly among tufts of mossy saxifrage in a shallow bowl are very pleasant to look upon in dull December. A cross between E. hyemalis and E. cilicica, which has been introduced under the name of E. Tubergeni, has larger, but paler coloured flowers than E. hyemalis.

Snowdrops, especially that fine variety, Galanthus Elwesii, should be planted as largely as possible, preferably in slight shade. The bulbs should be put in 3ins. deep and left severely alone, the pernicious practice of forking among them being strictly forbidden.

Muscari Heavenly Blue and M. alba grandiflora, are very pretty for cutting except that the blue—a very good colour by day—is dingy under artificial light. The curving sprays of Scilla nutans, with their white, pink or blue bells are most graceful in vases, while Milla (triteleia) uniflora (palest lavender) and M. u. violacea (lavender with a violet stripe down each petal), are particularly charming combined with mauve primroses and tufts of saxifrage. The milla bulbs are quite cheap and increase rapidly in almost any soil. The cutting value of Leucojum æstivum and the ornithogalums are scarcely fully appreciated, I think. Of the first named, the Gravetye variety has larger bells than the ordinary kind and is decidedly desirable; it blooms in May. The three ornithogalums most satisfactory in water are O. umbellatum splendens, an improvement on the old Star of Bethlehem; O. nutans, with spikes of silvery grey and pale green flowers—curious, but decorative—and O. arabicum, which has white flowers with black centres and golden anthers. The last requires a little protection in exposed situations; the bulbs should be planted 6ins. deep.

THE BUSY MAN'S PAGE

Flowers for Next Year.

MOST gardeners have noticed the sturdy development of self-sown plants, and this, in the case of certain hardy annuals, or plants that are often treated as such, is due to the fact that the specimens are able to get well established in the autumn. Try sowing clarkias, eschscholtzias, love-in-a-mist, Iceland poppies, cornflowers, sweet alyssum and coreopsis any time before the end of August, and you will make certain of a wonderful display of bloom next summer. By far the best plan is to make the sowings in the positions where the plants are to remain. This is really quite an easy matter to arrange, as patches in the borders are cleared. At the start, thin sowing is important and when the plants have grown a little, thin out once more. Perhaps even another sorting-out will be required, although one should leave rather more plants than will be ultimately required in order to cover any possible losses during the winter. Keep a sharp watch for slugs, woodlice, etc., for these pests will be active as long as the warm weather lasts and will be likely to fancy your seedlings. If the early autumn is very dry, watering will help the plants to get up to a fair size before the setting in of the winter.

SEEDLING POLYANTHUS SOWN IN MAY AND JUNE IN BOXES.

They are now ready for transplanting to their flowering positions. If planted out this month they soon establish themselves in their new situations. All divisions of primroses and primulas should be planted out in the same way.

Saving Seeds of Rock Plants.

THE seeds of many of the spring-flowering rock plants are now fully ripe. Helianthemums, many kinds of dianthus, ramondias, dodecatheon, androsaces, Silene alpestris, primulas, alpine poppies, saxifrages and many others, are covered with bursting brown cups and pods. The seeds should be collected as soon as possible in dry and sunny weather. A good method of gathering them is to put the seed-pods into the small tin boxes in which typewriter ribbons are sold. Any small tin box will do, however. When the box is half full, put the lid on and shake it vigorously; the seeds will easily come out, and the refuse of the pods can be gently blown off. The process may be repeated until the box is full. Label each box before putting it away. The tight-fitting lids of these cases make them excellent receptacles when it is desired to keep the seeds for any time.

Most alpine seeds should, however, be sown as soon as they are ripe. A seed trial ground is an interesting experiment in a rock garden. Cover a piece of level ground, in partial shade if possible, with 6ins. of light soil, loam, sand and powdered lime rubble and chips. In dry weather keep it damp by watering with a fine rose.

When collecting the seeds throw some of them loosely on this mixture, without attempting to cover them—Nature's own method of propagation. (It is well to put some kind of "bird-scare" on the ground.) Delightful surprises sometimes result from this casual seed-sowing. Difficult subjects will often root and grow with vigour, untended save by "Nature, that old Nurse," which, under experienced cultivation in frames, will not produce strong healthy plants.

How to Take Cuttings of Heaths.

IT is fairly generally supposed that cuttings of heaths are difficult to root successfully. This is not true, however, providing that one or two essential rules are followed. In the first place, the cuttings should be prepared from the half-ripened young shoots, an abundant supply of which will be procurable during August or early September, which is the best time to insert cuttings of these plants. Thin, weak shoots should be rejected as material for propagation, for they will never produce strong, sturdy plants. At the same time it is necessary to sound a warning against the choice of thick, sappy growths, for these invariably damp off if used for propagating purposes. As a rule the laterals growing from the young vigorous shoots make the best cuttings. They should be from 1in. to 1½ins. in length, and may be pulled off with a "heel" and trimmed with a very sharp knife. Should suitable cuttings with a heel be unprocurable, they should be cut cleanly across just below a joint. The lower leaves must then be carefully removed with the aid of a fine-pointed pair of scissors. Erica cuttings do not require much depth of soil in which to root, consequently the 48-sized pots should be filled to one-half their depth with drainage, a layer of leaves or moss being placed over the drainage to prevent the soil being washed away. The pots should be filled to within half an inch of the rim with a compost consisting of two-thirds peat and one-third sand, the peat being passed through a ¼in. sieve. A thin layer of sharp sand should then be sprinkled over the surface, and the pots watered through a fine rose and allowed to drain before the cuttings are inserted. From two and a half to three dozen cuttings can be accommodated in a 5in. pot, a small dibber being used to insert them, taking care that they are made quite firm. As each pot is filled, water with a can fitted with a fine rose, and then stand the pots in a shady corner of the greenhouse or cold frame and cover over with a suitable bell-jar. Exposure to sunlight must be carefully avoided.

Each morning the bell-jar must be removed and all condensed moisture wiped from off the inside of it. The cuttings must be watered when the soil becomes at all dry and any decaying leaves removed.

In from two to three months the young plants should commence to form roots, and ventilation must then be admitted, first by slightly tilting the bell-jar and then gradually increasing the amount until the jars can be dispensed with. The tips of the plants may then be removed to induce bushiness, and the following May a suitable opportunity should be chosen to plant out the young ericas in nursery lines, allowing 4ins. between the plants and 9ins. between the rows, and the following autumn splendid bushy little plants will be ready to transfer to their permanent quarters.

Clipping Hedges.

DURING a moist season hedges grow rapidly and quick-growing shrubs like privet require clipping several times to keep them neat. Those of slow growth—*e.g.*, yew and holly—do not get out of order if they are trimmed once annually early in August. Except in the case of laurel and holly, shears are the best implements to use, but they must be sharp at the outset. For large-leaved shrubs secateurs or a knife are best, as with either the leaves need not be cut. Always trim closely and aim at procuring an even surface by passing lightly over hollows and cutting hard back those portions that are projecting beyond the general outline. The top being the most prominent should be clipped with extra care, and if the operator is doubtful of his ability to do the job creditably unaided, he will find the garden line helpful when dealing with straight hedges. It is well to bear in mind when clipping that a hedge which is wider at the top than below will, sooner or later, become weak towards the base. After clipping is completed clear away all weeds at the foot of the hedge.

THE YOUNG PLANTS TRANSFERRED TO THEIR FLOWERING POSITIONS IN THE BORDER.

Note that each plant has sufficient space to grow freely. They are planted about six to nine inches apart.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Paths in the Garden.

IT is always a surprise to me that no two gardens seem ever alike. The garden illustrated on this page has quite a distinction of its own. The crazy paving paths are laid in an unusual fashion, according to the owner's fancy, the edge of each path being a ribbon of flowers of all kinds. Madonna lilies make a showy centre to the elliptical flower bed, while tall standard roses at intervals along the lawn side emphasise the division between lawn and path.

This front garden won a premier award in the recent Garden Championships organised by the London Gardens Guild, the judges considering that the standard of cultivation was extremely high. The grass, as the picture shows, is in perfect condition.

Contrast with this the second picture, where the path shown is straight. I, personally, prefer the straight path, with its arches of roses. Here again, the ribbon border which divides the lawn and path has been accentuated by becoming the home of numerous climbers which clothe the wooden arches with their blossoms. Without some such tall feature in this border, it would tend to appear unnecessary—one might be tempted to step over it. The straight path leads to a rockery garden and the whole design of this garden illustrates the value of variety in adding apparent size to the small town garden.

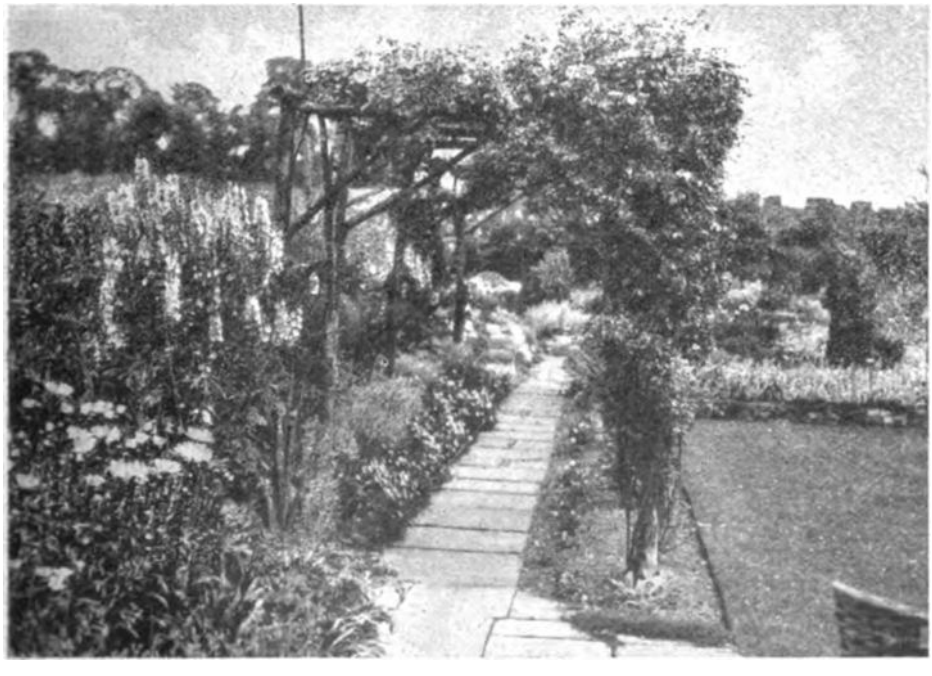
AN ATTRACTIVE FRONT GARDEN IN A LONDON SUBURB.
It is simply designed and well planted. The centre bed of Madonna lilies makes a most effective feature.

Chrysanthemums in Pots.

THE heads of early-flowering chrysanthemums are developing fast. Even now the earliest sorts are adding colour to the flower border. Beyond staking and thinning out of overcrowded shoots, there is little to do to border varieties. But plants grown in pots of the late blooming sorts, need more attention. As the flower buds begin to show, a dose of liquid manure should be given once a week. For this purpose soot water and manure water made by stirring animal manure in a barrel, should be given alternately. Where these natural stimulants are not available, a pinch of one of the prepared fertilisers should be given to each plant once a week.

If large blooms are desired, a certain amount of disbudding will have to be done. But for ordinary decorative purposes, the specially large blooms are not required. If mildew makes its appearance, spray the foliage with potassium sulphide (liver of sulphur), one ounce to three gallons of water.

The leaf miner is best checked by pinching the affected foliage between the thumb and finger to crush the minute grubs. Black fly is best kept in check by spraying with insecticide. Allow as much sunshine as possible to reach all the foliage and the reward will be an abundance of richly coloured foliage and flowers.



A STRAIGHT FLAGGED PATH WITH A BORDER ON EITHER SIDE.
This is a decorative feature in a small garden.

The Bulb Order.

THE arrival of early bulb catalogues is a reminder that the bulb planting time will soon be here. The bulb trade is no exception to the rule of first come, first served, or rather first come *best* served. Most growers grade their bulbs, and, naturally, the best quality are sold first. Early hyacinths that are required for Christmas decoration should be planted without delay. Among the daffodil section, Henry Irving, Telemonius plenus, Obvallaris and Paper White narcissus should be potted. Orders for outdoor bulbs should be dispatched as early as possible.

When bulbs arrive from the growers, they should be carefully unpacked and stored until required for planting. This is important as they somtimes get damp during transit. In selecting bulbs, size is not the only guide to quality. Weight is equally important. Further details will be given later on indoor and outdoor culture of bulbs in town garden.

After the Strawberry Crops.

AFTER the third season, strawberry plants are not worth keeping, and new plants must be raised. Where an old strawberry bed is now being dug over, seedlings of winter greens can be planted out. Give a dressing of fertiliser before planting, and set the seedlings 2½ft. apart each way. If onions are to be sown out of doors, these could be put in drills between the rows of winter greens. As soon as possible they should be transplanted or thinned out to 9ins. apart.

Remove Dead Flowers from Dahlias.

COLTNESS GEM, and other single dahlias, have been displaying their beauty for several weeks now. To prolong the flowering season, and to secure fine late blooms, cut away every dead flowerhead from the plants. Unless this is done the strength of the plant goes into the seed heads and less blooms are produced. This, of course, applies to other plants besides dahlias.

WORK IN THE FLOWER GARDEN

Chrysanthemums in Pots.

Watering them in Rainy Weather.

WHEN watering a number of chrysanthemums in pots one day in July, after rain had fallen, a friend made the facetious remark, "What, watering after all the wet last night!"—a remark which went to show that he was not a grower of them and led to the reason for the trouble and labour involved being explained.

It was demonstrated to him—to his satisfaction—that the pots being full of roots, and the leaves hanging over the sides of the pots, acting as a foi , and so preventing the rain reaching the roots, how necessary it was to guard against the plants becoming dried up, in what appeared to be a time when one could dispense with the water pot. In brief, in a time of plenty of moisture, one may overlook the need for water, and so chrysanthemums may become quite dried and starved.

Especially is this so with plants grown in moderate sized pots—5in. and 6in., for instance—that unless watered systematically are apt to lose their foliage, besides injuring the development of the buds. As a grower of some hundreds of chrysanthemums in pots, I know something of the task of watering and feeding, but it is a task never begrudged when I remember that from October until well on into January, there will be a reward of flowers which no other plant can possibly give, and whether the weather be wet or fine, they are examined every day while standing in the open, so that their needs may be satisfied. They are worth it all!—C.

Pools in the Rock Garden.

A MUCH greater interest is created in a rock garden by the presence of pools of fresh water. Such pools are entirely distinct from the fish or lily ponds, perhaps with paved edging, that are constructed in many gardens, often in conjunction with a rockery. These are formal, and obviously artificial, but a pool surrounded by rocks is the most natural use of water in the garden one can imagine. The introduction of a few pools of this nature allows a greater variety of plants to be grown with a consequent increasing interest in the garden. Many bog and moisture-loving plants can be placed round the pools to add colour to the rock garden during the summer months when the rich spring display is over.

It is quite an easy matter to make these pools, which need not be of any great depth unless lilies are to be grown; at all events, a chain of pools of varying depths could be formed across the rock garden, as shown in one of the illustrations, the first one near the source of the water being only 2ins. or 3ins. deep, and the last one 3ft., more or less.

A CHAIN OF POOLS OF VARYING DEPTHS CAN BE FORMED ACROSS A SMALL ROCKERY.

To ensure a circulation of fresh water, pipes from the main house supply must be led to the highest part of the rockery; and as this is expensive, it means that the rock garden should be as near the house as possible. A standpipe and tap can be will hidden among the rocks or shrubs near by, and the outlet pipe should be inserted among the rocks so that the water appears to be gushing out of a rocky mass. Let the water fall from one rocky projection to another and then run down a channel into the first pool, which overflows into the second pool, and so on, with, at the other end, an outlet into the drains, or perhaps the water can be allowed to spread itself over a bog garden near by.

A ROCKERY POOL CAN BE MADE AN ATTRACTIVE FEATURE IN MANY A SMALL GARDEN.

Along the channel and actually under the cascade will grow numerous ferns and other plants, and along the rocky banks of the pools can be planted mimulus, primulas of many kinds, forget-me-nots, acorus, king cups, loosestrifes, spiræas, funkias and many other moisture-loving plants.

The effect is far more charming than the perfectly square or round pool, as the illustrations demonstrate, showing how well this has been carried out by one of our readers, Mr. W. M. Frames of Sidcup, Kent, in a garden of average size.

Colour Schemes with Common Flowers.

THERE are certain plants that seem almost indispensable in the garden, and of these one is the delicate blue perennial flax, Linum perenne. This species is of light and delicate growth and lends itself to the formation of many pleasing colour schemes. Owing to its light and graceful habit, it may be associated quite freely with dwarf plants, as well as with those of taller stature. Last year I had a narrow border planted out with this flax and nemesia alternately, and the whole picture was one of entrancing beauty, the blossoms of the linum forming a veil of hazy blue over the brilliantly coloured nemesias. This year a similar scheme was adopted in a small bed, the companion plant in this case being Sweet William Pink Beauty instead of nemesia. The effect was equally fine, and I am hoping to have a further display in late autumn in this way. The linum is cut down to within a few inches of the ground—to promote new growth that should flower later in the year—and in the place of the sweet william, now pulled up, are planted pink antirrhinums, grown from a late March sowing. There are many more ways in which this linum may be utilised, and the above notes must be taken merely as suggestions of one or two lines which might be followed up.

Linum perenne will come quite freely from seed sown outdoors in shallow drills at this season, and the resultant seedlings need not be transplanted till late autumn if thin sowing be practised. A good stock of seedlings should be raised, for bedding out schemes usually swallow up a goodly number of plants.

Another indispensable plant is the mauve catmint, easily raised from cuttings, as described in recent issues of this journal.

Digitized by Google

Nepeta Mussinii, as it is botanically named, will flower continually from June till September, the mauve blossoms being borne in light and elegant spikes. Mauve is a colour that associates well with most other shades—bar scarlet—but, perhaps, the happiest blending is with pink. Thus, the schemes that suggest themselves for a narrow, and perhaps rather dry, border are—an edging of mauve catmint, with the main part of the border planted with pink flowered annuals, such as Godetia Schaminii, Lavatera rosea, pink clarkia, etc. Nepeta, with a backing of the delightful pink antirrhinum Nelrose: and nepeta with pink, silvery-leaved carnations.

The mauve catmint is also invaluable for growing on old retaining walls and for any bare bank or piece of rockwork which is not in total shade. Plants growing under these conditions may be allowed to remain for several years, and will in the course of time reach a very large size. For edging purposes, it is better to replace the plants after the second year, or they will overspread the whole border.

A New Evening Primrose.

Œnothera Clutei.

THIS new evening primrose is a native of Arizona, where it was discovered by Mr. Willard Clute in 1919 when botanising in the Navajo Indian Reservation Territory. This species was described by Nelson and named after the collector. During the spring of 1926 Mr. Clute sent seeds to Mr. T. Hay, superintendent, Hyde Park, and to him we are indebted for our plants. This species is evidently a biennial, as the first season it formed a large rosette of leaves. During the second year it throws up a stout central shoot about 4ft. in height. From the base of this other less strong lateral shoots have developed, altogether forming a large handsome plant. The flowers are large, about 4ins. across, and are borne in great profusion. In colour they are of a soft yellow like Œ. biennis, but the petals are not so broad and regular as in the later species, but are open or show light at the base and open out almost flat in the form of a Maltese cross, giving the flower a distinctive and pleasing effect. Flowering, as it does, with great freedom, a mass of this plant is very effective, and if it ripens seed, which it has every appearance of doing, it should prove valuable for grouping in the mixed border or planting in large masses in the semi-wild parts of the garden.—J. COUTTS.

THE NEW AND ATTRACTIVE EVENING PRIMROSE, ŒNOTHERA CLUTEI.
From the basal rosette of leaves it throws up a long flower spike some four feet high carrying soft yellow blossoms.

How to Trap Earwigs.

THESE cause the gardener no small amount of anxiety. Their love of dahlias and chrysanthemums, to say nothing of rose and other blooms, is at times enough to try the patience of the mildest of men. The old and favourite method used by dahlia growers is to place a flower-pot on the top of the stake. This is good enough, but try putting pots on the ground as well. Fill them with paper and examine them every day. Other methods include tying hollow stems of plants about the plants affected. Rolls of paper will do just as well. A splendid plan is to fix up a number of match boxes among the plants. Fill these with moss or similar litter and leave them part way open. The pests need some place in which to hide during the day, and such receptacles as these provide them. The advantage of using matchboxes, dried hollow stems, rolls of paper, etc., is that when found full of the pests they may simply be destroyed and fresh ones provided. A daily examination should be made. Insecticides may deter the earwigs but will not get rid of them.—T. H. H.

An Attractive Globe Flower.

(Trollius pumilus yunnanensis).

WHEN any reference is made regarding a trollius, we immediately think of the globe flowers and the various forms of T. europæus, but the plant named above is quite distinct, and the flowers resemble a large richly coloured buttercup. In T. pumilus we have a dwarf plant about 6ins. in height, which produces light yellow flowers in June and July above a tuft of small glossy leaves. This plant is suitable for a moist situation.

The variety yunnanensis was, I believe, introduced by Purdom some eighteen years ago, and it is an excellent subject for the bog, or wherever the soil is on the damp side. It is finer in all its parts than T. pumilus, the scapes are branched, and the beautiful bright golden yellow flowers are nearly flat and fully 3ins. across. In the centre of the five massive sepals is a circle of paler yellow stamens, while the light green foliage is both ample and pleasing to the eye. In the garden here it is nearly 2ft. high, and had over twenty flowers open at one time. A clump of six or eight such specimens is quite a feature during late June and early July. Like many other members of this group, they resent root disturbance, and having planted them in a sunny but damp position, they should be left alone for several years. Propagation is effected by division in early spring and by seeds. These, if sown as soon as ripe, will readily germinate in a cold frame, and healthy seedlings will be the result.—T. W. B.

The Fishbone Thistle.

Chamæpeuce Casabonæ.

THIS is a noble-foliaged plant of the Composite family. Most authorities underestimate its height, giving such as from 2ft. to 3ft., whereas it would be truer to write 3ft. to 5ft., and even 6ft. in a congenial place. The plant shown was nothing short of 6ft., and with the purple flowers crowning its thistle-like head made a conspicuous subject. The chief glory of this fishbone thistle is, of course, its fine leaves, of a shining greyish green colour with a white mid-rib and small brown spines on the ends of the leaves.

THE HANDSOME-LOOKING FISHBONE THISTLE WITH ELEGANT GREY FOLIAGE.

A light or well drained soil is necessary to obtain well developed plants, otherwise the plants are stumpy in appearance and correspondingly less handsome. The wild garden would be a suitable place for this thistle if the ground is porous and the site not overshadowed too much. It is best treated as a hardy biennial, its flowering-time being July to August.—C. T.

Michaelmas Daisies—The Worth of Final Staking.

IT is a fact, one may see demonstrated every autumn, that many people who grow Michaelmas daisies in their gardens do not get full value from them, because they fail to recognise the importance of giving the plants enough stakes. Looking over a border a few weeks ago, I noticed most of the plants had been given one stake earlier in the season, around which a cord had been loosely tied. This was altogether inadequate, for many shoots were sprawling on the ground, and the wood having become hard, it was quite impossible to get them in anything like position without breaking or injuring them. It is well, even at this date, to examine Michaelmas daisies with a view to giving them help in this direction, as if left to themselves wind and rain beat them down. Three or four stakes about a plant with twine drawn around them will often prevent an accident.—W. L. L.

Cheiranthus Allionii: Planting Out in Autumn.

MANY gardeners make the mistake of letting seedlings of this cheiranthus remain until the following spring before getting them into their final quarters for blooming. But when lifting the plants thus late, the long tap root is severed, and many of them die away. It is better to shift the plants in autumn before the roots have become too strong. C. Allionii does not like disturbance at all, and I would much prefer to sow thinly on a bed to themselves, or prick out the young seedlings as soon as large enough, and leave them at that, but one cannot always do so, as I am convinced that most of the failures occur with large plants that have pushed out their long tap roots, and when these are once broken, they take a long time re-establishing themselves.—F. W.

NURSERIES OF THE BRITISH ISLES.—IX

MESSRS. R. H. BATH, LIMITED, OF WISBECH.

THROUGHOUT the British Empire Messrs. R. H. Bath of Wisbech are known as raisers and growers of narcissi and tulips. Their fame in this connection has spread far and wide largely owing to the very fine exhibits of these bulbous plants which this firm have displayed at the R.H.S. shows and other floral exhibitions. They have introduced some of the finest of our modern narcissi and are one of the pioneer bulb-growing firms in England. To discover the beginnings of the firm one must go back to the eighties of last century, when Mr. R. H. Bath founded, in 1880, the Floral Farms at Wisbech, which is situated near the Wash some ten miles inland. At first the nursery was devoted solely to the cultivation of fruit and vegetables, chiefly raspberries and strawberries. As many as 250 acres of the former and 150 of the latter were grown. As the soil in the neighbourhood of Wisbech is all alluvial deposit reclaimed from the Wash, the firm realised that their land was particularly suitable for the culture of flowers and bulbs. A start was made with wallflowers, foxgloves, polyanthus, pansies and sweet williams, and in 1894 over 40 acres of pansies alone were grown for the markets throughout England. At first only a few acres were planted with bulbs, but so successful were they that within a few years over 100 acres of bulbs were grown at the Floral Farms. Ever since then the bulb industry at Wisbech has steadily increased, until to-day Messrs R. H. Bath are one of the leading and largest bulb-growing firms in the country.

A FIELD OF EARLY-FLOWERING TULIPS AT THE WISBECH FLORAL FARMS.

THE GLORY OF THE SNOW (CHIONODOXA LUCILIÆ) GROWING UNDER FRUIT TREES AT MESSRS. BATH'S NURSERIES.

Narcissi, tulips, gladioli, crocuses, chionodoxas, snowdrops, muscari, and bulbous irises all flourish remarkably well in this rich alluvial soil, and they do equally as well as those cultivated in Holland; the chief difference being that the bulbs are generally smaller, but, on the other hand, they are much hardier and in some cases flower better than Dutch-grown bulbs. It is an interesting fact to note that Messrs. Bath sold to Dutch buyers and shipped to Holland during last year 20 tons of narcissi grown on the Floral Farms.

This firm has shown untiring energy in the development and improvement of the daffodil and tulip, and for the last twenty years they have met with great success in the raising of new narcissi. They have sent out many new varieties, all of which have been given awards of merit by the R.H.S. and have proved themselves valuable garden varieties. Bath's Flame is one of the most notable, and during last year 150,000 of this variety were sold. Scarlet Perfection, Advance Guard, Premier, Golden Sunrise, Orange Glow, Phyllida and Scarlet Beauty are merely a few of the fine narcissi which have been introduced by Messrs. Bath. Narcissus Premier is a uniform deep yellow throughout. The flowers are of perfect form, 4ins. in diameter, and of beautifully smooth texture, and nearly every flower is up to exhibition form. It is very vigorous and free, and Messrs. Bath consider this variety to be one of the best yellow Ajax they have raised. They have also purchased the entire stocks of new varieties from other raisers; in fact, they have the largest stock in the country of many of the new varieties. A considerable number of their new daffodils are sent abroad, particularly to New Zealand and Australia. This year 2lb. of hybrid narcissus seed was saved and sown, probably a record quantity of narcissus seed saved by any firm in one season. The narcissus specialist in particular should make a point of visiting the Floral Farms during April, when about three acres of narcissus seedlings can be seen in flower, for he will find much to interest him.

DAFFODIL PREMIER.

Raised by Messrs. Bath and shown for the first time this year.

It was tulip-time when we paid our visit to Messrs. Bath's nursery. We were taken from one tulip field to another. Each field was a blaze of colour and a magnificent

Digitized by Google

sight. Reds contrasted with yellows, pinks blended with mauves and purples, a veritable sea of waving heads. The early tulips were over, but the Darwins and cottage tulips were in their full splendour. Over 12 acres are devoted to the cultivation of tulips, and every year the beds are changed, for this firm does not advocate the planting of tulips on the same land two years in succession. The bulbs are lifted, graded and planted out on fresh land which has been worked to a depth of at least 12ins. and given a good dressing of bone meal. Narcissi follow the tulips, and the former are always sterilised before replanting. Messrs. Bath have one of the largest sterilising plants in the country. In the six tanks which they possess they are able to sterilise 6 tons of bulbs per day. It is this sterilisation and constant change of land that ensures all Messrs. Bath's bulbs being so very vigorous and healthy.

It is impossible in the short space at our disposal to give an adequate description of the many fine varieties which we saw on our visit. There were tulips of every colour and shade to be seen, some of the new bronze varieties being particularly attractive. The well known Clara Butt, which is still the best pink Darwin both for garden and market purposes, was in good form. Quaintness, a variety of golden brown flushed rose; Yellow Picotee, a small-flowered yellow tulip edged with pink; W. T. Ware, of deep yellow colouring; and Inglescombe Yellow, a variety which forces well, are a few cottage varieties which we selected as being particularly suitable for the amateur to grow. Dido is a new cottage tulip, one of the largest and most beautiful of all tulips. Illumination was a striking tulip of clear yellow and red; The Sultan, a handsome maroon-black Darwin; King Harold, another fine tulip of dark maroon scarlet; Bleu Aimable, one of the most attractive and distinct of the bluish mauve Darwins; William Pitt, with its vivid cochineal red blooms; William Goldring, a true ruby red; Valentine, an early Darwin of pale purple violet; Prince of Orange, a rich orange scarlet cottage tulip; and Flamingo, a tall-growing Darwin of soft rosy pink, were other outstanding varieties. A particularly good bedding variety was Petrus Hondius, which is a clear and brilliant cerise. Other good varieties were Orange Globe, Violet Queen, Blue Bird (one of the bluest of tulips) and Princess Elizabeth. Rembrandt tulips are one of Messrs. Bath's specialities. They have introduced some of the most effective and interesting varieties, each possessing unique combinations of colour.

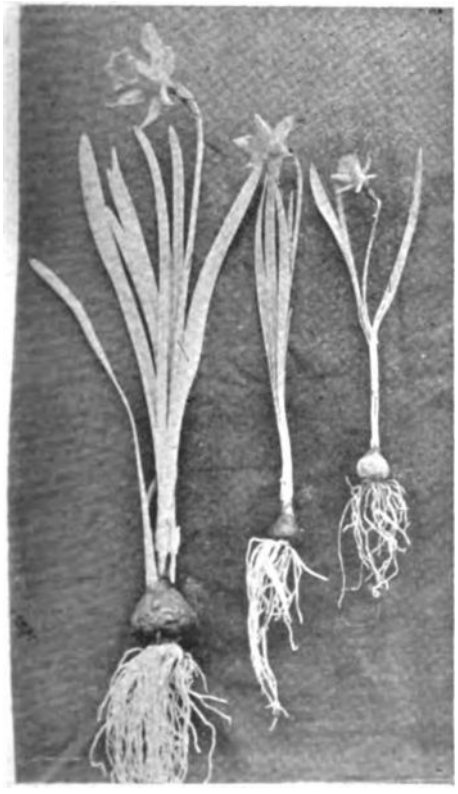
Many other plants besides narcissi and tulips are grown on the 392 acres of land which comprise the Floral Farms at Wisbech. Messrs. Bath possess a fine stock of pyrethrums, and they have introduced two of the best of the modern border varieties, namely, Harold Robinson and Eileen May Robinson. These two very successful varieties have large blooms of good substance, they are strong growing and should be included in every herbaceous border. Harold Robinson, a rich crimson scarlet pyrethrum, is very vigorous in growth, and Eileen May Robinson, with its long-stemmed pink blooms, is a beautiful flower for cut purposes. Herbaceous phloxes, peonies and delphiniums also occupy considerable space. Their collection of peonies contains the best varieties raised both in Europe and America. In recent years gladioli have received considerable attention at the Floral Farms, and at the present time there are 8 acres devoted to this plant alone. This firm are busy raising new varieties, and many of these will shortly be put on the market; while among the hybrid primulinus gladioli they have a number of striking new introductions, one being a variety of an uncommon shade of a delicate rose pink colouring.

Muscari and chionodoxas are also grown in very large quantities, and last year as much as 1½ tons of M. Heavenly Blue were planted. A number of acres are devoted to the cultivation of roses, dahlias, pansies, gooseberries, strawberries and raspberries. Bath's Empress pansies, a special strain of fancy pansies, have become famous throughout the world, and a large stock is raised annually, for this strain is always in great demand.

WHAT OUR READERS SAY

DWARF DAFFODILS.

SIR,—We send you the accompanying illustration showing relative sizes of the miniature daffodils—minor, nanus and minimus. The figures are about a third natural size. All are distinct from one another in form. In the case of the true minor, the corona at margin is more open and flanged than in nanus and the perianth segments are more twisted. A variety sent out from Holland under the name of minor appears to be a somewhat larger plant, slightly taller than our minor and with flowers a little larger. It reminds us of one of the wild French forms sent to us many years ago by a botanist at Grasse (France). Our minor originates from a stock which was grown by the late Rev. John Nelson.



THREE TYPES OF DWARF DAFFODILS. *Narcissi minimus, nanus and minor.*

The true Narcissus nanus is found in many old gardens in Ireland. The variety which has often been sent under this name from Holland is a different plant altogether, namely, lobularis, which is a larger plant of a different colour and not so attractive.

Narcissus minimus is the smallest and dwarfest of all trumpet daffodils, as well as the daintiest and only grows about 3ins. to 4ins. high.—MESSRS. BARR AND SONS, *London, W.C.2.*

A PLANT FOR COVERING A FENCE OR WALL.

SIR,—Where it is desired to cover an ugly wall or wooden paling, there are few more effective flowering plants than Solanum crispum, the potato tree, and though a native of Chile, is perfectly hardy in most places.

It throws out strong lateral branches which can be trained as desired, and has a sequence of large clusters of blue purple coloured flowers. The plant illustrated has been in flower for a month and continues to throw out fresh blossoms; though only planted two years ago, it already covers 12ft. by 6ft. of paling. The strong leader shoots thrown out should be cut back or tied in as they grow; if this is not done the growth is so vigorous as to become unsightly.—M. P., *Hants.*

SOLANUM AS A SCREEN PLANT FOR A FENCE.

HARDY FUCHSIAS.

SIR,—During July, August and September, the rock garden and shrubbery is not overdone with flowering subjects, and it has been a source of wonder to me that hardy fuchsias are not more frequently seen in gardens, especially in the southern counties. Near the coast they are often met with, and in Cornwall I have seen them employed as hedge plants. Farther inland the only one frequently seen is F. Riccartoni, and in some instances it develops into quite a large bush, while occasionally it is cut down by frosts, but only to break up from the base again with renewed vigour. Other fuchsias that should be tried include F. corallina, which is aflame with colour in August and September. Such examples are most effective on the rock garden, especially where they can be raised to the line of vision, and perhaps falling gracefully over a large rock. Then we have F. pumila, like a miniature Riccartonii. F. macrostema, of which there are some nice varieties, such as globosa, and the slender gracilis.

Fuchsias enjoy a light loamy or sandy soil, the chief essential being a rooting medium which retains a certain amount of warmth. Full sunlight is desirable, then the twiggy branches assume an attractive brightness.

Digitized by Google

Sunshine and warmth will produce large bushes, laden with blossom in late summer, and during the majority of our winters they will escape injury to any great extent. Cuttings root readily from roots in August or September, and it is a profitable plan to keep a few examples in a cold frame or cool greenhouse during the winter to replace any casualties. There are many positions in gardens where fuchsias would produce that bright bit of colour so desirable late in the season.—B., *Chepstow.*

A DECORATIVE BROOM.

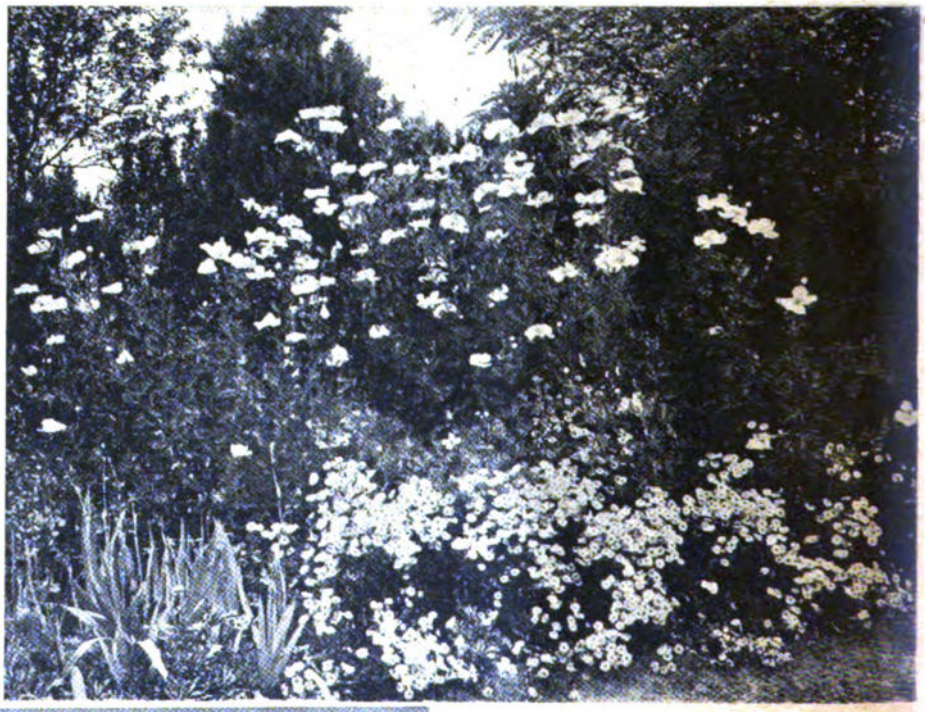
(*Cytisus racemosus*).

SIR,—Most gardeners will recognise this beautiful plant as a greenhouse subject, and at one time quantities were grown in 5in. pots for Covent Garden Market, while larger examples were often seen in private gardens under glass. Grown under such conditions very fine specimens are obtained, but even so they are much inferior to those planted out in a more or less sheltered part of the garden. Here they grow freely and the terminal spikes of bright yellow flowers are 8ins. to 10ins. in length. No protection is afforded during the winter months; and in a vicarage garden near Chepstow is a specimen several feet high and as broad. The plant was bought a few years ago in a 5in. pot for dwelling-house decoration, and after flowering it was merely transferred to the garden, where it has developed into quite a healthy and free-flowering shrub. This idea could be put into practice by many, and other plants more or less hardy could be treated in the same way, rather than throwing them on the rubbish heap directly they have served their original purpose. C. racemosus is said to attain a height of 3ft., but outside it will exceed this figure, and during May the plants will be a mass of bloom. Little or no pruning is needed, but, as a rule, it pays to give the plants a slight trim over when the flowers are past their best, and this will also prevent the formation of seed pods. This subject can be raised from seeds, but often the resultant seedlings are mere weeds compared with the original, so cuttings constitute the best and most reliable means of propagation. These are made from partially ripened shoots and will form roots if given a little bottom heat in July or August.

Examples growing in pots in the greenhouse should be cut back fairly hard and when they have started into growth, they should be repotted, shaking away as much of the old soil as possible, without disturbing the roots to any great extent. When established, a few weeks in the open will ripen the growth and, consequently, induce them to flower freely when brought under glass about October. C. racemosus is reputed to have been introduced from the peak of Teneriffe in 1835, but it may be a plant of garden origin.—C.

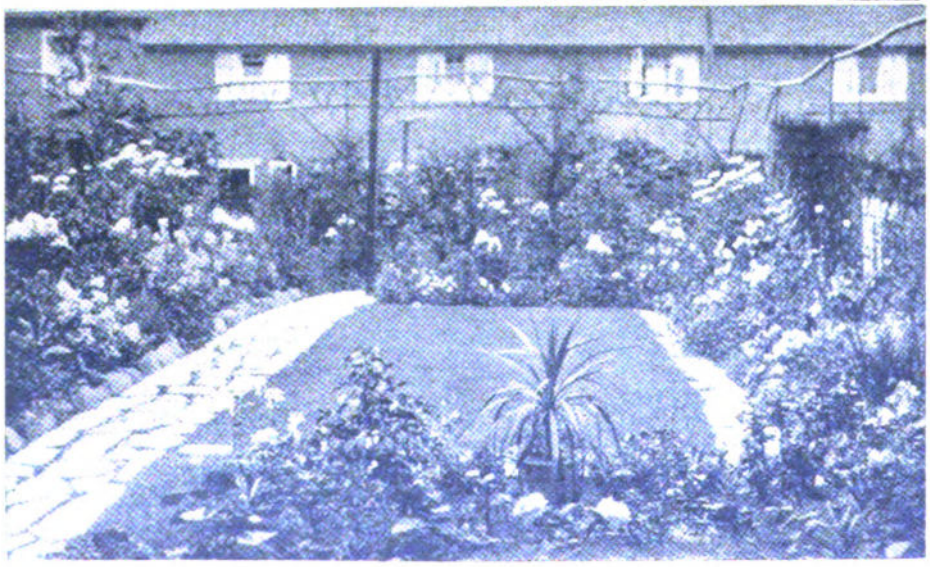
OUR PHOTOGRAPHIC COMPETITION

This competition will close in our issue of September 17th. Readers are requested to send in photographs before that date. Many of these may not be published in our competition pages, but will, if suitable and of sufficient interest to readers, be published in other pages.



The Californian tree poppy, Romneya Coulteri, makes a most delightful addition to the large herbaceous border or other part of the garden where it can be allowed to extend at will. The large white, delicately crimped flowers are greatly enhanced by the mass of golden anthers, besides which a delicious perfume pervades the surroundings for some distance. It may be propagated by root cuttings and, once established, requires no further attention beyond cutting to the ground in early spring before growth commences.

The guinea photograph, sent in by L. W. OLIVER, 40, *Broughton Hill, Letchworth, Herts.*



Only nine months ago my garden was left in a very rough state by the builders. Since then by hard work I have got it in its present state. In the borders are phloxes, delphiniums, aubrietias, Michaelmas daisies, Chrysanthemum maximum, and also stocks, asters and antirrhinums. These last three plants I raised myself from seed.—MR. F. W. ASHBY, *Parkstead Road, Roehampton, S.W.*15. Award of 5s.

Digitized by Google

The secret of beauty in a flower garden is to grow those plants which make happy and robust growth. These clumps of Primula Beesiana are a joy each year. They edge a rocky pool in the lowest part of the garden. This species of primula is a most accommodating plant and succeeds perfectly in such a situation.—MISS M. GRAHAM, *Oakland Avenue, West Hartlepool.* Award of 5s.

This terrace, which overlooks the tennis court, is paved with bluish-coloured bricks, and the path edging, bench and tubs which can be seen are made of concrete. This method of paving is most effective, and its colouring makes a pleasant contrast with the purple-black heliotrope in the border.—MISS HELEN INGERSOLL, *East Setanket, New York.* Award of 5s.

This photograph, taken in May, 1927, is of a Derbyshire rock garden which was made by the owners out of a field. The big broom in the back is the white broom. In front of it is Cytisus præcox. The large bush of Erica arborea in the foreground was raised from a tiny slip.—MRS. W. WILSON, *Holmesfield, Sheffield.* Award of 5s.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Substitute for Moss.

A good substitute for moss for covering over the crocks in plant pots before filling up with compost—especially in dry districts where moss is hard to find—may be found in Arenaria montana pulled from the random paving. It is also excellent for sending away flowers by post.—P. B.

Lilium candidum.

Unless it is imperative to remove clumps of bulbs of Lilium candidum, they are best left alone, especially if they are doing well; but if they must be shifted, it should take place immediately after the flowering stalks have died down, and before the new growth has advanced. Too often removal of the bulbs is put off late in autumn, when new growth is in evidence, and it is seldom they take kindly to a late shift. To those who want to buy new ones or remove old ones, do so without delay. But if a clump is giving satisfaction and yielding its pure white blossoms, every season, I strongly recommend its being left undisturbed.—D.

Lobelia in Winter.

At the approach of autumn I have always pulled up my lobelias and thrown them away with other annuals. However, last year, I called on a friend just before Christmas and was surprised to see beautiful lobelias in masses of bloom growing indoors in a pot. They made a very uncommon and effective splash of colour and my friend assured me that they had bloomed all through the autumn from the time she transplanted them from the garden. This year I have resolved to pot mine up in the same way.—D. W.

How to Keep Pot Plants Alive While on Holiday.

Place a pail of water on a pair of steps and beneath and around it as many pots as can be accommodated. Now tie as many pebbles as there are pots to strings and drop the pebbles in the pail, allowing each piece of string to hang over or lay upon a pot. The continual dripping will thus keep alive many plants that would otherwise perish. Adopt this method also in a greenhouse by using three or four strings to each pot.—B. P.

Lifting Potatoes.

When the foliage turns yellow, it is time to dig up early potatoes. The work must be done promptly, otherwise, should the weather turn very wet, the tubers are almost certain to be ruined by disease. Another reason for avoiding delay is that the ground is cleared for another crop. Store the tubers in a cool, dark place, or clamp them in ridges in a convenient part of the garden. The ridges should be low and thatched with turves or straw to exclude light. Tubers set apart for seed should be of even size, shapely and free from blemishes. These need not be placed in the dark, but, on the whole, they will be best clamped for the present.—G. F.

A Cheap Fertiliser.

Since animal manures have become so scarce and costly, I have had quite wonderful success by following this plan: Whenever a section of the garden becomes vacant—after potatoes, shallots, peas or tomatoes, I at once seed it down in rape or red clover. Using these alternately and the growth is dug in when about a foot high. On one spot (unfenced), where I must grow potatoes or nothing, by keeping to this practice, potatoes have been grown for fifteen consecutive years, and the crop is still good and clean. It sometimes happens that by taking up potatoes early in August it is possible to get two crops of green manure turned in before winter stops the growth.—H. R.

To Prevent Midges.

A small smouldering fire is the best preventive. Get a large baking tin, have a couple of iron supports soldered on underneath to keep it about 2ins. off the ground, also a light chain fixed to two sides about 3ft. long so that the tin can easily be carried, like a censer. Then when at work in the garden, light a small fire in the tin, throw a handful of weeds on it now and again. This will smoulder beside you and can easily be carried by the chain, from place to place, and all midges and flies kept at bay.—H. M.

BULBS FOR SCOTTISH GARDENS

THE cultivation of bulbs in the open and in pots has made substantial progress in Scotland during the past ten years. Not only is the popular trio consisting of daffodils, hyacinths and tulips more extensively grown, but the public have discovered that among the lesser-known species, of which camassia, fritillaria, chionodoxa, muscari, ixia and scilla are typical, there are floral gems that succeed under simple treatment and contribute to the glory of the garden at a time when there is usually a dearth of colour in bed and border. But there are other indications of increased interest being taken in these bright harbingers of spring. Amateurs who were content with the results obtained from the cheaper or standard varieties are now specialising in up-to-date sorts for pot culture. This is particularly noticeable in the daffodil classes. Old favourites, such as Emperor, Empress, Victoria, Golden Spur, Sir Watkin and Barrii conspicuus, still represent the bulk of the retail trade, but within the past four or five years there has been an improving demand for higher-priced novelties that find a place in the catalogues of enterprising seedsmen. Bulb shows that were non-existent in war time have come into vogue again, and their reappearance has been followed by greater activities and stimulated enthusiasm on the part of competitors and the general public.

In this good work representatives of the trade have given a helping hand. Messrs. Austin and McAslan, for instance, have established a spring show in Glasgow, which has provided an object-lesson in successful bulb culture. The support given to the competitive side has justified the enterprise, while the educative influence of the private exhibits is reflected in the large attendance of flower-lovers. Mr. J. Montgomery Crawford, Barassie, Ayrshire, is another pioneer, and although his efforts are on a smaller scale, they have been attended with an encouraging measure of success. He specialises in the newer daffodils, and at the annual exhibitions held at Highfield visitors will find such choice specimens as Carnation (the scarlet-white double), Crœsus, Dragon, Fireball, Firetail, Golden Sunrise, The Marquis, Treasure, Queen of Hearts, together with seedlings of his own raising, of which a new poeticus variety has been called Lindberg.

Daffodils are probably the finest of all hardy bulbous plants and one of the least fastidious. Most varieties accommodate themselves to almost any soil and situation, but they prefer a rooting medium that has not been heavily manured. According to the late Dr. Crawford, who was a well known authority on bulb culture, the safest manures consist of basic slag, bone meal and potash. The treatment he advised is as follows: Sprinkle 4 oz. of slag or bone meal to one square yard in the trench where the bulbs are to be planted and lightly mix these commodities with the bottom soil; then dust the surface after planting with sulphate of potash at the rate of 1½ oz. to the square yard.

Daffodils may be planted in the months of September, October and November, but the earlier the better, as it is advantageous that the roots should be formed before the

THE ATTRACTIVE POETAZ NARCISSUS, A FINE FLOWER FOR GARDEN AND HOUSE DECORATION.

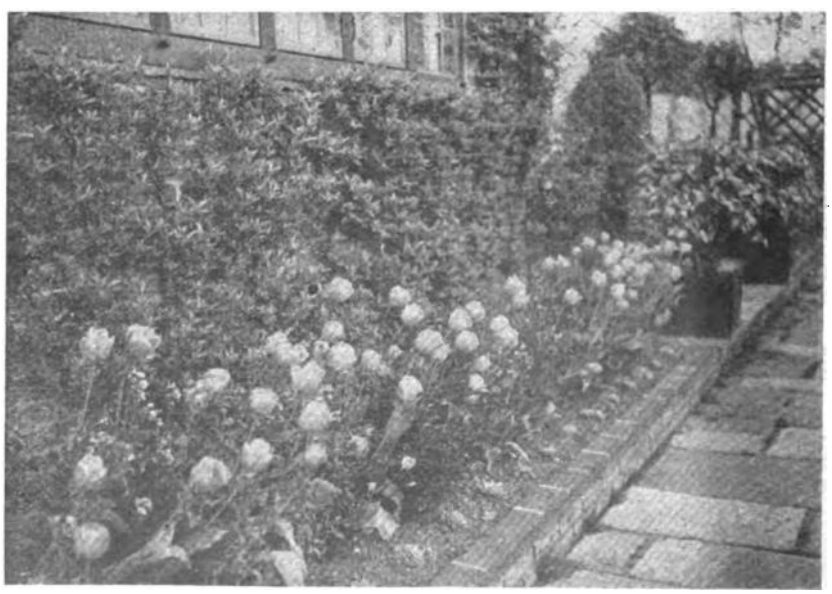
ground becomes too cold. Rare or expensive varieties are safer planted in virgin soil, which should neither be too heavy nor too light, and best results are got from shallow planting, which means that the top of the bulbs should be about 3ins. under the surface of the soil. When grown in the border daffodils are most effectively arranged in clumps of not fewer than three or four, but their grace and charm is accentuated when established in grass.

Among the large trumpet sorts Golden Spur is indispensable for early bloom, while Emperor, Empress, Grandis, Horsfieldi, Glory of Leiden and Cervantes are the best of the cheaper yellow and bicolor groups, and when finances permit, the claims of Van Waveren's Giant or King Alfred, the best of the golden trumpet daffodils, should not be overlooked. In the chalice cupped section Gloria Mundi, Sir Watkin, Lucifer and Frank Miles offer a sufficient choice, and if there is space one or two clumps of Barrii conspicuus and the Poetazhy brids deserve a place, as they remain a long time in flower and are useful for cutting.

HYACINTHS.

To obtain blooms for the decoration of the home at Christmas hyacinths should be potted in September in a compost of turfy loam and leaf-soil with sufficient sand to render the mixture porous, and additional bulbs may be planted at intervals of two or three weeks with the view of providing a succession of bloom. To encourage root development before top growth begins plunge the pots in ashes to a depth that will ensure a covering of a few inches. Watering is unnecessary if the soil is properly moistened when put into the pots. Before the top of the flower-spike pushes through the ashes remove the pots indoors and place them in a subdued light, and after the top growth has assumed its natural green colour it can be exposed to full daylight near the glass, where the pots may remain until forced into flower. Bulbs of one variety should be selected for pot culture, and three bulbs are sufficient for a 6in. size. The cynthella or miniature hyacinths are well adapted for ordinary pot culture, and they cost about a half less than the ordinary bulb; but if the latter are preferred, try Jacques, pale rose, which produces a handsome pyramidal spike; Grand Maitre, deep lavender blue with large bells; and Edith Cavell, one of the finest pure whites.

Grown in small beds out of doors hyacinths make a charming colour display, especially when situated in a lawn. Late planting and deep planting tend to delay the period of bloom, and as a rule late flowering in the open is preferred, as the plants are less liable to injury from frost. October or November is therefore a suitable time and, generally speaking, the bulbs flower better and only a few days later when planted to a depth of 9ins. The ideal soil for hyacinths is a light sandy loam that has been deeply dug and enriched with old cow manure a month or so before planting. Heavy land should be forked over and a liberal supply of sand added. Some growers also make a practice of surrounding the bulb with sand to further improve the drainage. Hyacinths lend themselves to varied colour schemes and combinations. Harmonious effects can be obtained by planting varieties of red, white and blue together, or associating white with blue or red, pale yellow and dark blue, or different shades of any of these colours are very pleasing to the eye. A bed composed of pale blue and cream hyacinths is, to my mind, the prettiest of



A BORDER OF EARLY-FLOWERING TULIPS.

Digitized by Google

all. These colours may be arranged in alternate rows or sections, but an arrangement that finds favour with many gardeners is to plant square and circular beds with a single and double row of one colour and fill up the central part with another colour to harmonise.

EARLY TULIPS.

Owing to their wider colour range the early-flowering tulips possess greater decorative possibilities than the other members of the popular trio. They are as accommodating as the daffodil and, being very much cheaper than hyacinths, they are favoured by growers of all classes, but especially by amateurs possessed of limited cash resources. Like all other bulbs, tulips require a well drained soil, and they can be planted when conditions are suitable from mid-September until mid-November. Plant the bulbs 4ins. deep, and the size of the leaves which are sent up necessitate a space of 5ins. or 6ins. between the individual bulbs. The Duc Van Thol varieties are best for early flowering, and a later and more brilliant colour display may be obtained by planting single or double varieties, such as Prince of Austria, orange scarlet; Thomas Moore, terra cotta; Prosperpine, carmine rose; Prince de Ligne, golden yellow; Max Havelar, orange flushed salmon rose; and Kaiser Kroon, crimson with yellow margin.

The beauty of a bedding display may be enhanced by associating tulips with forget-me-nots, aubrietia, double white arabis, alyssum and other dwarf subjects that bloom about the same time and which may be used as carpeting or edging. There is probably no finer sight in the spring garden than a bed of Kaiser Kroon, but if something uncommon is wanted, try a colour combination of Queen of the Violets and any yellow variety.

There is an increasing demand for Parrot tulips, a gorgeous and distinct species with brilliant coloured flowers of grotesque forms. They make a fine display in borders in succession to the early varieties and remain in good condition when used as cut bloom. Among the cheaper varieties are Mark Graaf, yellow, scarlet and green; Café Brun, coffee colour and yellow; and Perfecta, striped red and yellow.

OTHER BULBS.

Apart from their showy appearance in the garden, the Spanish and Dutch irises are invaluable for the supply of cut flowers in late May and early June. They are among the cheapest of bulbous flowers, and should be planted early in the season, as the bulbs are small and are apt to become soft by late autumn. As these types of iris sometimes attain a height of 24ins. to 30ins., they should never be planted singly. Grown in clumps they give variety of colour to a mixed flower border, and if space permits a bed of iris arranged in rows of one colour rainbow fashion makes an impressive show.

Not later than September plant snowdrops in large clumps 1in. apart and 3ins. deep. The crocus is a general favourite and a plant of easy culture, and may either be naturalised in grass or arranged in a fairly broad line near the path. It should also be planted early after the same manner as the snowdrop. Other useful spring-flowering bulbous plants are the grape hyacinth (Muscari Heavenly Blue), dog-tooth violets, Scilla sibirica (a pretty little blue flower which makes a good companion to the snowdrop), Chionodoxa (the Glory of the Snow), camassia and fritillarias. They should all be planted in October. J. Y.

THE FRUIT AND KITCHEN GARDEN

Fruit Trees on Walls.

FRUIT trees trained on walls often suffer through drought at their roots at this season. Although we may experience heavy showers of rain during the summer months, and as a result the soil in the open borders is fairly moist, that at the foot of walls will be found almost dry. Much too dry the soil will be where the ground has a gentle slope, and dust-dry where the incline is sharp. For the benefit of my fruit trees in such positions I always fork up—just loosen—the surface soil and pour in clear water several times until sufficient has been applied to moisten the soil to the lowest roots. Then I follow up with a good dose of liquid manure, taking care to leave the soil loose and not to tread upon it. In the case of late pears I find that the fruits benefit as well as the buds and trees generally. Where summer pruning has been done there will be now as a result numerous young shoots growing from the cut-back stumps of branches, and all such shoots should be pinched out forthwith. Where trees are so treated the experienced cultivator can see at once how well they are being prepared for next year's crops. Trees from which the fruits have been gathered should be thoroughly syringed several times. —GEORGE GARNER.

Duration of Strawberry Beds.

IT is impossible to lay down any hard and fast rules as to the length of time over which a strawberry bed will produce on a profitable scale. Beds have been known to crop abundantly for seven years, or even more; but, as a rule, after three years there is a tendency to deteriorate. After the third year the plants should be watched closely for signs of wearing out one of the most important being the formation of small crowns; other indications are a falling off in the size and quantity of the fruit produced. On a deep rich loam the beds may well be allowed to carry on into the fifth year; but on light and poor ground there will be a marked falling off in the crop after the third year. To maintain a succession of plants at their best, a certain number of rows should be destroyed each year and a similar number planted with young healthy stock. Where the soil is of an extremely light nature one year old plants sometimes give the best returns, and here new quarters must be made up each year. If the plants are set in rows from 2½ft. to 3ft. apart, the beds can be worked in connection with the early potatoes, and these can be followed immediately by the late broccoli, the latter crop being worked in without digging.—L. B.

Grow Apricots.

RIPE apricots are so delicious that it is a wonder more people do not grow this fruit. Contrary to a common idea, apricots are not really difficult to manage and, if a few points are borne in mind, the trees usually bear well. As the planting of an apricot tree should take place directly the leaves fall in the autumn, the preparation of the position should be carried out in the late summer. The apricot must have a warm wall. On the whole a due south aspect is the most suitable, but, failing this, the next best is south-west. It is a mistake to plant apricots with a south-east aspect, for the tree, being very early with its development of flowers, is likely to suffer from cold winds and frost. Best of all the apricot likes a deep, somewhat heavy loam, and it is essential that the drainage should be good. Where the soil is not quite so good as might be wished it is an excellent plan to work a barrow-load of good loam into the situation. Apricots also appreciate lime and, except in chalky or limestone districts, old plaster or lumps of chalk may be profitably dug into the soil. The apricot dislikes fresh manure in contact with its roots, and for the enrichment of the ground one should use bone meal, mixing half a gallon freely with the soil where each tree is to be planted. Fan-trained trees are the best to plant and spur-pruning is the proper system to adopt with apricots. Summer as well as winter pruning is needed, and the removal of large portions of branches is to be avoided as this encourages gumming. Whenever there is space train in young stems, and if the spurs, as the side shoots bearing fruit-buds are called, become too long, shorten them to about half their length. In a dry summer the trees should have weak liquid manure occasionally if they are to bear heavy crops. They will also benefit by a top-dressing or mulch of decayed manure 3ins. or 4ins. deep which is applied in the spring. Thinning of fruit should be started in good time when the fruit is about the size of peas. Remove the smaller ones first and complete the thinning after the formation of stones has commenced, when the fruits will be about the size of walnuts. Anything like overcropping on the part of the tree will result in small fruits of poor quality.

It is usually necessary to protect apricot blossom to make certain of a good crop. Two or three folds of herring netting suspended from the top of the wall will answer the purpose. The best variety of apricot for general planting is Moor Park. Frogmore Early, which is ripe at the end of July, is somewhat small, but it is very sweet. Hemskirk is another early form with larger fruits of good flavour. Another excellent variety is Blenheim, which ripens immediately after Frogmore Early.

Harvesting Onions.

TOWARDS the end of August in the southern counties the large-bulb onions are, usually, ready for lifting, drying and storing. In the northern the middle of September will be soon enough to store the big bulbs. Only in a few cases should the big specimens be grown on into October, when they are required for exhibition, as late-lifted bulbs rarely keep well. I have seen large bulbs lifted and shown early in August that have kept sound through the winter longer than those even of medium size have which were harvested late in the season. If they become marked—weathered—no treatment afterwards, however good it may be, will arrest the general decay of the bulbs. The latter should be quite sound in every way when they are stored. One week at least prior to lifting, carefully remove the soil from the base of each large bulb, almost exposing the roots. When engaged in lifting place the fingers under the bulb and pull up the roots. If the weather is dry and settled, lay down the bulbs with the roots towards the south; if the weather is unsettled, lift the bulbs while they are actually dry and place them on a dry base in an open shed or in a cold frame, but be sure that the lights are well tilted, otherwise the heat may do some harm—scald the skin. When thoroughly ripened and dried the bulbs should be stored without unduly cleaning them.—HANTS.

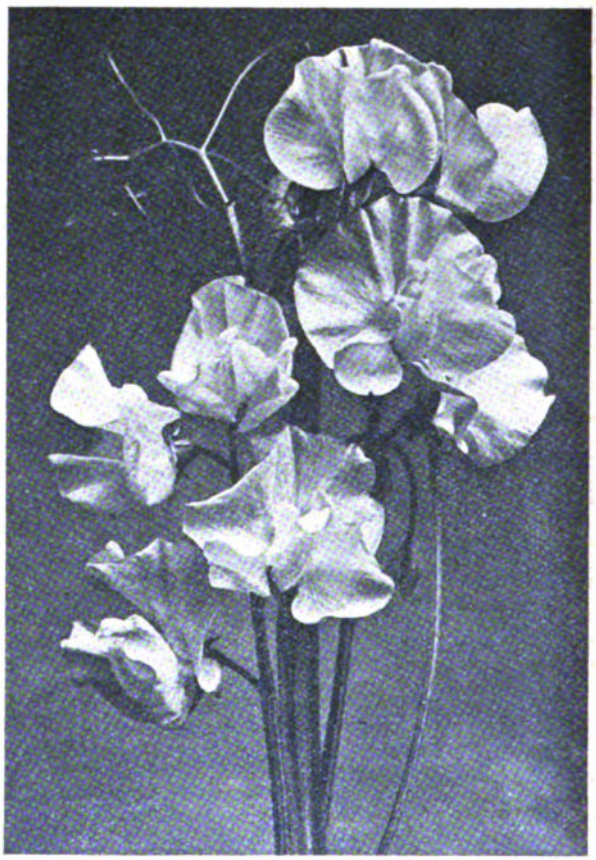
FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

ARE the judges of the Scottish Sweet Pea Trials too generous in their awards? This question was raised by an amateur exhibitor when the results of the past seasons observations were made known at the Show and the view was taken that honours should only be given when the seedling was distinct or was recognised as an improvement on existing varieties. The opinion was further expressed that with the exception of Mrs. A. Searles and probably Pinkie, the new sweet peas showed no advance when compared with those placed at the head of the respective colour classes. and that the multiplication of too-much-alike varieties should be discouraged by the English and Scottish Societies. But how, it may be asked, is that ideal to be realised? Are all synonyms to be censored by these two governing bodies? They might, of course, withhold a certificate of merit, but that policy would not prevent a raiser from distributing a new variety and the fact should not be forgotten that there are several popular and meritorious sweet peas in commerce to-day that have never received official recognition. Sybil Henshaw, admittedly the best of the crimson class, is a case in point and there is the anomalous position of Mrs. Searles, which did not qualify in the English trials, but was considered worthy of a gold medal when tested in Scotland. Besides, that high award is not always to be relied upon as an indication of the merits of a new variety, for it is common knowledge that the subsequent results of the individual test are sometimes at variance with the official trials. Olympia, the recipient of the Scottish gold medal last year, is most disappointing this season. The complaints are general. Both in private gardens and when exhibited it has been inferior to Royal Purple, particularly in the size of the bloom, all of which suggests that trials are simply an independent test of the purity of the stock, while the bestowal of honours may be taken as an indication of the vigour of the plants and the condition of the peas at different stages during the period of observation. After all is said and done, the grower—whether he belongs to the numerous constituency of enthusiastic amateurs whose ambitions do not extend beyond the decoration of the garden, or the more advanced body of exhibitors—is the ultimate judge of the merits of these so-called novelties, and he is usually a reliable guide.

There is probably no other town in the west of Scotland where so much enthusiasm and friendly rivalry exists among gardeners, as at Cumnock, and the inhabitants generally are proud of the success of the local competitors at the Glasgow Show. At the opening of the show of the Cumnock and District Sweet Pea, Rose and Carnation Society, Miss Moore, who formally opened the exhibition, and ex-Provost Miller, who presided, congratulated the prize winners at Glasgow and specially commented on Mr. McMillan's achievement in the carnation classes. That grower further added to his reputation at the local show by winning six classes of carnations and picotees. He also won the Society's silver trophy for the most meritorious exhibit of sweet peas. The nine vase class was won by Mr. James Logan; while a vase of Magnet grown by Mr. Robert Smith had a triple honour bestowed on it, being awarded first prize in its class, special prize in the section for growers with over 300 plants and the prize for the best vase in the Show. Although the rose classes were weak as the result of the first blooms being over, Mr. E. McMahon staged a specimen of the fine crimson variety, Capt. Kilbee Stuart, which was of a high exhibition standard and secured the award given for the best rose in the Show. Mrs. McMillan exhibited a choice collection of carnations and Mr. David Smith's stand of roses and sweet peas was noted for the number of new varieties. Miss Moore has presented the Society with a silver bowl and there are hopeful indications that next year's show will excel all previous exhibitions.



THE GOLD MEDAL SWEET PEA, MRS. A SEARLES (CERISE) AND ST. MUNGO (CREAM PINK), SILVER MEDAL.

The rambler roses are making the countryside gay, contributing a wealth of colour to gardens and brightening many drab places in our industrial towns. Dorothy Perkins, Excelsa and American Pillar are in evidence everywhere.

As all the roses of the Wichuriana and climbing polyanthus types produce their bloom on the new wood of the previous year, amateurs are reminded that they require different treatment from the dwarf bedding forms of hybrid teas and hybrid perpetuals. Any pruning that is needed consists of cutting out the old wood on which the present season's bloom was produced and this should be done after the flowering period is over, towards the end of September. All dead wood and weak straggling growths should also be removed. It will be noticed that strong growing shoots are sent up from the base of each plant and the best of these should be retained to replace the old shoots and furnish the bush with foliage for next summer's bloom. When the weather is not favourable to the ripening of the new wood in autumn, the stems sometimes die back in winter and it is, therefore, advisable to leave more than is actually required to provide against losses. If this treatment is observed any superfluous growths can be cut away in spring.

SCOTTISH SWEET PEA TRIALS

THE results of the sweet pea trials conducted by the Scottish National Sweet Pea, Rose and Carnation Society at Helensburgh were announced on the opening day of the annual show held at Glasgow, and in accordance with custom vases containing specimen blooms of the meritorious varieties were staged for public inspection.

GOLD MEDAL.

Mrs. A. Searles, sent by Robert Bolton and Sons. This glowing cerise variety contained a rogue in the Reading trials, but during the two years it has been grown in Scotland the stock was quite fixed.

SILVER MEDALS.

Pinkie, raised by Morse and Co., California. A deeper toned Hebe that made an outstanding bowl when exhibited by Messrs. Dobbie and Co. at the Chelsea Show in May. It had the high honour conferred upon it as the favourite bloom chosen by Queen Mary from among fifty varieties.

St. Mungo, raised by George Bowness, Busby. In my notes this seedling is described as the best cream pink in the trials. A strong grower with occasional double standard blooms.

Charm, raised by J. Stevenson, Wimbourne. Quite distinct from Mrs. Searles and might be described as an improved Charming, with which it may be confused when in commerce.

CERTIFICATES OF MERIT.

The Admiral (Cullen and Son, Witham). A new shade of deep blue. One of the largest peas introduced; numerous four-bloom stems.

Victoria (W. J. Bland, Victoria, British Columbia). Quite a pleasing lavender, but I do not know that it is any advance on existing varieties of that colour class.

No. 86 (Dobbie and Co.). A Mrs. Tom Jones blue that may possibly displace the older variety.

Mountjoy (W. E. Sands, Lisburn) and *No.* 35 (Robert Bolton and Son). Both belong to the cerise colour class, which is already too numerous.

Corona (Cullen and Son). The rose flowers are large and well formed, but the colour is not so fashionable as it used to be.

Auld Reekie (George Bowness). This variety was in a backward condition at my first inspection, but it has come on satisfactorily and was staged in good form. It is a big cream pink flower lighter in colour than St. Mungo.

Hero (Morse and Co.). Consistently good in the trials, a dark coloured cerise with plenty of four blooms on long stems.

No. 68 (J. Stevenson). There were two rose varieties in the trials, and it is a coincidence that each received a certificate.

Glorious (J. Stevenson). Another good cerise which will probably increase the perplexities of growers who have only space for one representative of that colour in their collection.

ST. MUNGO.

LUPINS—CHOCOLATE SOLDIER, OPAL, DELIGHT, SUNSHINE, PENELOPE.

WATERER'S LUPINS

THESE are now available in the most exquisite shades and colourings and should find a place in every garden. Our collection contains all those varieties worth growing. The five which are illustrated in colour are of exceptional merit—

Colour Collection

CHOCOLATE SOLDIER— Dark chocolate keels with yellow standards — each 1/6

OPAL—Opal blue .. 2/6

DELIGHT—Carmine lake 3/6

SUNSHINE—Rich butter yellow 1/-

PENELOPE — Soft blue veined and suffused dark blue with rose tipped standards 1/-

The collection of **6** varieties carriage paid and packed free. **8/-**

For further particulars, see our advertisement on page x.

Write for a copy of our 112 page hardy and alpine plant catalogue, containing full particulars of our large collection. We will gladly send it post free.

THE GARDEN

VOL. XCI.—No. 2908. AUGUST 27, 1927. PRICE TWOPENCE.

INCREASE YOUR VIOLAS FROM CUTTINGS

IF you want to keep your violas true to colour and type, cuttings are the best means of doing so. A great deal towards success is a correctly prepared cutting, and this is a failing with many people, but a little practice works wonders. There are two chief advantages derived by propagating from cuttings in preference to division of roots. Plants resulting from cuttings are, as a rule, more vigorous; also, they can be procured in large numbers.

This is about the best time to make a start, so long as the weather is favourable. Growers will notice that after removing first cuttings from the old stool, further growth will quickly follow, so that a steady supply may be relied on.

The Right Type of Cutting.—The most likely are from the basal shoots, as these are not hollow, being of recent growth, and, if properly trimmed and inserted, seldom fail to root; this type of cutting may also be obtained when the old plant is in flower, and may sometimes be pulled off with small roots adhering to them, this being an excellent start for an amateur grower. Shoots must be cut off well down into the crown of the plant; they are then of a firm and woody nature. Another type of cutting is that obtained from lateral growths; very often one is reduced to these as our favourite coloured plant fails to make the required basal shoots. It is necessary when wanting lateral cuttings to be very careful to overlook your plant first, and any shoots that are 2ins. or 3ins. long should be broken off at the axil of the stem. Take off the lower leaves and bracts; they are then ready for the prepared bed in a cool frame. One point that should be guarded against is, trying to get cuttings from long, coarse roots that have been bearing flowers practically all the summer. If, by a stroke of good luck, these do root, they will never make satisfactory plants, being, as all stems are, quite hollow. According to the time you wish to bed out, so you must treat your old plants. Often it is a good plan to bed a few old stools in a spare corner; you can then avoid spoiling your showy flower beds in the front of the house. Cuttings should be from 2½ins. to 3ins. long. Having obtained all you require, the next move is to a cool and shallow frame.

Loam, leaf-mould and silver sand must be passed through a sieve, this being well mixed and dug in several inches deep. The bed is then levelled, trodden very firm and watered. When moisture has well soaked in, proceed to insert cuttings in rows about 2ins. apart, with a similar distance between each plant. A small, short dibber must be used, and holding the cutting at its apex with the left hand, having made the hole about 1in. deep, insert the cutting, and with the right hand drive the dibber into the soil close to the hole, thus you force the soil against the cutting and at the same time fill in the cavity. By this method, no pressing of the soil with the fingers is required. A thick layer of sand should always be spread over the surface of the bed previous to planting. The frame lights should be kept tightly closed and shaded well for the first few days; cuttings will soon root under these conditions, and splendid plants will result, these same standing the winter weather well. Like most plants, the viola has its enemies and diseases, the chief being red spider, which lives in a fine web spread over the leaves of both pansy and viola. They suck the skin of the leaves and makes pale patches on them. The best remedy is: 2 oz. of soft soap in a gallon of water, as this pest hates moisture. For slugs or snails, powdered lime and soot is the cure, also bran laid in heaps on the bed is effective. Mildew is a rather frequent bother, which appears in grey patches on the leaves and causes them to shrivel up. The worst affected leaves should be hand picked and burnt; then spray with 1 oz. sulphide of potassium dissolved in a quart of boiling water, and made up to 2½ gallons with cold water.

The Value of a Margin.

WHETHER it be in the flower domain or in that part of one's garden devoted to the culture of vegetables, it is a mistake to overcrowd plants or to make use of the whole of the space at one's disposal at the first onset. How often do we find it is the ground we left spare for "nothing in particular" that comes in opportune for something we had overlooked and yields good results. In the case of ground already occupied by crops, we may, if we have sown seed too thickly, make amends by judicious thinning while seedlings are young. Too often the injunction to "sow thinly" is overlooked, and this is the only way to put matters right. Overcrowded vegetables never give a good account of themselves, and flower seeds are mostly sown much too liberally in a confined space. It is well to bear in mind that it is the individual plant which has proper room for development which invariably turns out the best. Ground left vacant can always be put to good advantage afterwards. It comes in useful for a variety of things, for sowing later seeds, for pricking out biennials or other plants we may not have bargained for, for providing standing room for chrysanthemums and other plants for winter flowering that are being prepared by open air treatment.

This Week's Work

For Gardens in the South and Midlands.

Take cuttings of geraniums, verbena, calceolarias, marguerites, fuchsias and other bedding plants.

Pot up freesias and Paper White narcissi.

Make a sowing of winter spinach.

Sow seed of Primula malacoides in pans of light sandy soil.

Insert hydrangea cuttings.

Cut out old fruiting wood of black currants and raspberries.

Transplant seedling spring cabbage.

Clean up and mulch asparagus beds.

This Week's Work

For Gardens in Scotland and the North.

Propagate loganberries by layering the points of young shoots.

Begin planting holly, yew or laurel hedges.

Increase apple and pear stocks by budding.

Pot up Roman hyacinths.

Sow East Lothian stocks.

Dig late potatoes when the haulm begins to wither.

Repot arum lilies.

Trap earwigs on dahlias and chrysanthemums.

Transplant late varieties of broccoli.

Begin harvesting onion crop.

Prepare ground for new lawns or greens.

Plant English iris.

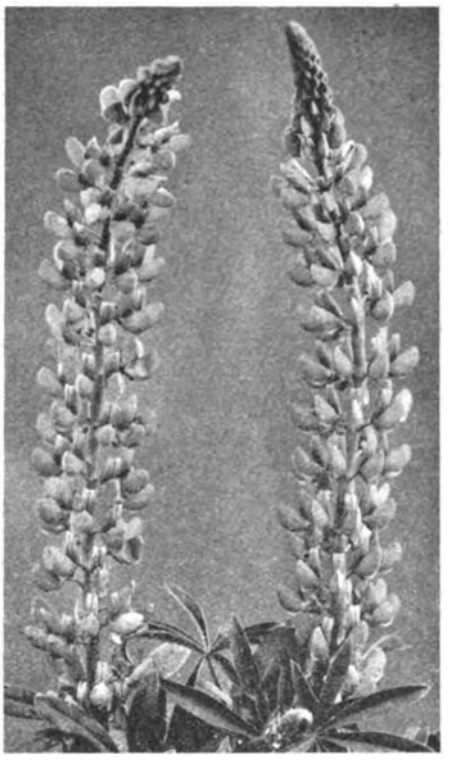
Digitized by Google

LUPINS FOR PRESENT PLANTING

No garden is complete without lupins. They are among the most decorative and brilliantly coloured plants for the early summer. They can be planted during the next few weeks.

FEW plants are more valuable for decorative effect in the garden, whether grown singly or in masses, than the hybrid lupins which are the happy result of crossing and re-crossing the old L. polyphyllus—still to be reckoned among the best of the blues—with L. arboreus. These beautiful hybrids may be planted in either autumn or early spring, but on the whole, the former is the best time to choose. They like plenty of sun, but are not exacting as to soil, although they prefer one that is not heavily charged with lime and is on the moist, rather than the dry side; indeed, they succeed particularly well if planted at the edge of a pond or stream, in which their tall spikes will be reflected delightfully. The odious slug is the worst enemy of the lupin and it must be fought with every weapon available. The ground round each plant may be watered with a solution of alum, or ringed round with the latter mixed dry with ashes. Sanitas powder is effectual but expensive if many plants are to be protected, and encircling them with rings of galvanised iron or with strips of felt soaked in paraffin will—sometimes!—baffle the foe. In dry, hot weather, lupins should be plentifully supplied with water, otherwise they may drop their buds, and a little weak manure water given when the flowers begin to open will help them.

Many of the newer hybrid lupins are shaded in combinations of colours which sound bizarre but are in reality wonderfully harmonious. One of the most striking is Chocolate Soldier, illustrated on the front cover of this issue, an introduction of Messrs. Waterer Sons and Crisp's, in which deep reddish-purple, chocolate-brown and yellow are blended. This lupin would make a good centre, or culminating point in a large mixed group. Less striking in colouring, but very attractive are the same firm's Dresden China, the keel of which is French grey, deepening to lavender, while the standards are shaded from pale yellow to white; Glow-worm, bluish-mauve deepening to violet with gold-tipped upper petals; and Cinderella, silvery lilac shaded with creamy-yellow. Mayflower and Opal, both raised at the Twyford Nurseries, are respectively porcelain-blue and white and a beautiful opalescent shade. They would combine well with lupins of stronger tones of blue, such as Hawker and Friar of the well known Downer strain, in an "all-blue" border. A very pretty planting scheme is one which includes blue lupins and peonies in soft tones of pink and rose, with white Campanula persicifolia in front, while another good combination is that of white foxgloves, lupins shading from blue through gold to cream and white, and June-flowering flag irises in blue, yellow and white. Lupins and irises are always charming together and a wide border of irregular outline



LUPIN GLOW-WORM, BLUISH-MAUVE WITH A GOLD TIP TO THE PETALS.

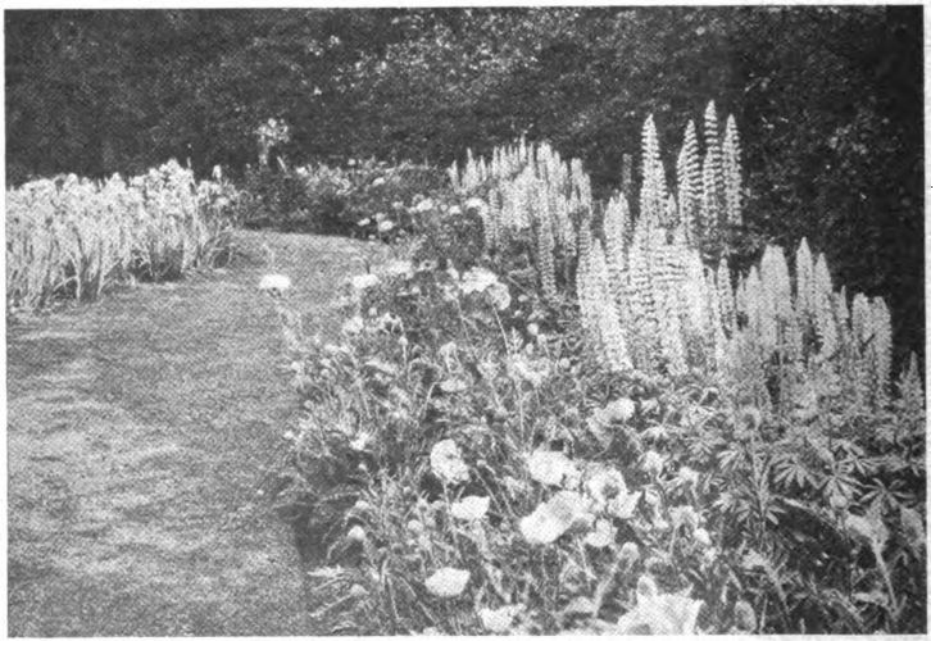
flanking a broad turf walk, filled entirely with masses of lupins and irises, either all blue or multi-coloured, without any other flowers, is a most beautiful sight in early summer. Groups of lupins in a mixed border are always effective, but here the question of succession is apt to arise; this, perhaps, can be best solved by interspersing the lupins with delphiniums and planting phloxes immediately in front of them and hollyhocks behind, an arrangement which will extend the beauty of the border until the end of August or thereabouts.

A very great improvement has taken place in pink and red lupins of recent years; they are no longer insipid or dingy as in the past was too often the case, but clear, soft, shades which look well either alone or in combination with other colours. There are some beautiful pinks among the more modern lupins raised by Mr. Downer at Chichester, notably Pink Pearl, which is really rose-colour, Irene Hamilton and Beacon, both pure pink, Wright, deep pink; and the very dainty Tunic, shell pink and white. Other fine lupin varieties are Artist, delicate blue with a hint of rose colour; Delight, warm red; May Princess, blue purple; May Queen, royal purple; Victoria, almost plum colour; and Countess of March, the flowers of which open almost white, but become gradually flushed with rosy-wistaria, deepening with age. This fine variety, however, is not at present on the market, as the stock is not yet large enough for distribution. Many of the hybrid lupins have this chameleon like tendency to change colour as the flowers reach their full development, but, unlike such transformations in many other plants, the alteration in hue is usually pleasing.

Really good yellow hybrid lupins have been, until lately, scarce. Now, however, Messrs. Harkness and Sons of Bedale have raised, among their Regal strain of lupins, a number of beautiful yellows—ranging in shade from the warm cream of Mrs. Sivewright to the golden bronze of Marjorie—which are perfectly hardy. A group of these, including, besides the two named, Gold Crest, Ada, Hilda Wilson, Yellowhammer, Advance and Cleopatra, would make a gorgeous picture, especially if seen against the purple-brown foliage of Prunus Pissardi or the copper beech (Fagus sylvatica cuprea).

A list of some of the finest of the hybrid lupins, other than those already mentioned, is given below.

Some good hybrid lupins for planting this autumn are Attraction, violet purple; Armageddon, deep purple blue shading to light blue; Brightest and Best, rose red; Beauty of Somerset, pale yellow, flushed pink; Blue Star, bright blue; Chelsea, medium blue; Chameleon, blue and yellow, changing to blue and white; Enchantress, white; Effective, yellow and white; Geraldine Kelway, shell pink; Hilda Wicks, Wedgwood blue tinged mauve; Icicle, white; Joy, pink and gold; John Harkness, mahogany red; Milkmaid, blush white; Mount Everest, white; Prince of Orange, orange shading to buff; Queen of Sheba, violet and gold; Red Star, red purple; Sunshine, buttercup yellow; Twilight, mauve; 21st Lancers, mauve and orange; Wargrave Beauty, rosy mauve. R. E. HEAD



LUPINS, IRISES AND POPPIES—A BLAZE OF COLOUR IN EARLY SUMMER. *This is an arrangement which many amateurs should try.*

BULBS TO BUY NOW

The following notes should serve as a guide to those who are in doubt as to what bulbs to select for flowering in their garden next spring.

FOR several reasons, ordinary people with ordinary gardens must find it extremely difficult to know what to buy in the way of fresh varieties when the time comes round for them to send their requirements to the bulb dealer. They see, comparatively speaking, little that is new in their neighbours' gardens, and they have no opportunity of visiting large shows where the newer varieties are displayed. Perhaps, too, last year or the year before, some did take their courage into their hands and bought some unknowns, but those unknowns did not turn out the success that was anticipated, and when the time for ordering comes round again—what then? The catastrophe is too recent to be forgotten. "Once bitten, twice shy," "No more dark horses," "Old friends are best"—sentiments like these are very near the surface when the next order is made out. The result is, "I had better stick to what I have had before." This, of course, is very likely the wise and only thing to do under certain circumstances: as when, outside, a colour scheme has to be considered, or when, indoors, the drawing-room is all in all; but in an ordinary way among ordinary people who have ordinary gardens, we would suggest that a trial be given every year to one or two novelties—something, that is to say, which they have never grown before. No variety is too common to be included. This production is intended to be a sort of horticultural cocktail made of bulbs. It is to be hoped that that the contents are good and will prove of use.

ANEMONE.

The St. Bavo strain, flowers from mid-March to mid-May; so bright and jolly. St. Brigid. Giant French.

CAMASSIA.

So easy to grow, so distinct, and so uncommon.

Cusickii (lavender).
esculenta (rich blue).

CHIONODOXA (GLORY OF THE SNOW).

Luciliæ (blue with white centre).
sardensis (gentian-blue self).

CROCUS (SPECIES).

If these are strangers, try a few early-flowering ones; then, next year, speciosus and zonatus, which bloom in autumn.

Imperati (heliotrope and fawn).
Susianus (yellow).
versicolor (white).
Sieberi (mauve).
Tomasinianus (lavender).

ERYTHRONIUM.

American varieties which want shade and damp, but well drained soil. Try them.

grandiflorum (yellow).
Johnsoni (rose-pink).
Hartwegi (buff).

GRAPE HYACINTH (MUSCARI).

Heavenly Blue (rich blue).
plumosum (for a cold house).

HYACINTHUS.

The species mentioned is truly a hardy gem.

amethystinus (a real pale blue).

HYACINTHS (DUTCH) FOR THE OPEN GROUND.

First-sized bulbs are too heavy. I prefer *second* or even *third* sized bulbs.

General De Wet (pale pink).
Grand Maitre (blue).
Lady Derby (rose pink).
General Pelissier (red).
Innocence (white).
Schotel (pale blue).

FOR POTS.

It is necessary to get *prepared* hyacinths to have flowers at Christmas. I prefer Cynthellas (miniature) to larger-sized bulbs. The same varieties do duty for both Cynthellas and also for larger bulbs.

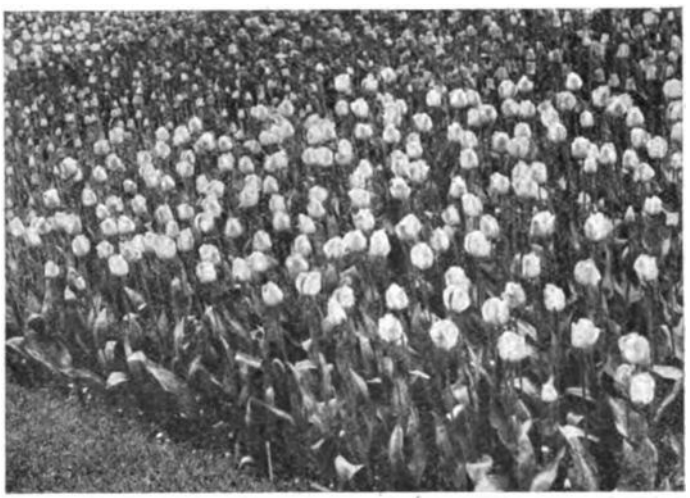
Innocence (white).
Queen of Pink.
*Orange Boven (ruddy apricot).
Jacques (pale pink).
*Menelik (darkest blue).
King of the Blues.

(* Second-sized bulbs recommended. Two or three first-sized bulbs for those who like the old-fashioned big spikes.)

Chestnut-flower (semi-double pink)
Distinction (not large, claret).
Corregio (white).
Johan (lavender).
Perle Brillante (pale blue).

TULIPS.

As in the case of daffodils, varieties are as the sand of the sea shore in number. To reduce these to tabloid form in a thoroughly satisfactory manner is beyond the power of man. The more you know, the more hopeless does it seem; yet this means that those who know but little, need all the more help. For detailed descriptions catalogues must be consulted.



A GOOD TULIP FOR OUT-OF-DOORS, THE LAVENDER MAUVE WILLIAM COPLAND.

(1) DARWINS.

A FINE TEN FOR OUT OF DOORS.

Clara Butt (pink.)
Eclipse (maroon).
Edmée (rose edged pink).
International (ruby-red).
Petrus Hondius (rose).
Suzon (pale pink).
William Copland (lavender-mauve).
Faust (very dark).
Millet (rich crimson).
Pride of Haarlem (cerise).

(2) COTTAGE VARIETIES FOR OUT OF DOORS.

Avis Kennicott or Mrs. Moon (deep yellow).
Boadicea (mahogany and orange).
Gesneriana major (bright crimson).
Marksman (scarlet).
Moonlight (pale primrose).
The Fawn (fawn and cream).
Bronze Queen (biscuit brown).
Ellen Willmott (primrose).

(3) FOR POTS (EARLY VARIETIES).

To get away from the beaten track, we suggest:

Brunhilde (white, yellow flamed).
De Wet (magnificent orange).
Prince of Austria (sweet orange-red).
Rising Sun (rich yellow).

(4) DARWINS FOR POTS IN MARCH.

Baronne de la Tonnaye (rose edged blush).
Pride of Haarlem (cerise).
The Bishop (purple).
William Pitt (dark scarlet).
Erguste (lavender-mauve).
Farncombe Sanders (rosy scarlet).

(5) SPECIES.

Dasystemon (white, large yellow centre).
Kaufmanniana (palest primrose).

IRISES (BULBOUS).

There is a good deal of uncertainty about the names of the varieties in the different sections. The Dutch flower the first, then the Spanish. Dutch and Spanish need light ground.

(1) DUTCH.

Apol (lavender and white).
Rembrandt (blue and yellow).
Van Everdingen (yellow and cream).
David Bles (violet-blue).
Van der Helst (pale yellow).
Voerman (white).

(2) SPANISH.

Cajanus (yellow).
Prince Henry (purple and bronze).

THE GLORY OF THE SNOW, CHIONODOXA SARDENSIS, IS A BULB EVERYONE SHOULD PLANT.

Digitized by Google

Rossini (lemon and white).
Souvenir (soft mauve).
W. T. Ware (primrose).
Queen Wilhelmina (white).
Royal Blue (deep blue).
Thunderbolt (bronze).

(3) SPECIES.

reticulata (blue-purple and orange).

NARCISSI (DAFFODILS).

Daffodils for show are outside the purpose of these selections. Most red edges and red cups burn planted out of doors. Most varieties except the polyanthus-narcissus varieties and the small species do well in grass. In grass plant clumps or drifts with one variety only, never plant mixtures. See dealers' lists for detailed descriptions.

TWELVE VARIETIES FOR OUT OF DOORS.

Barrii conspicuus (red edge to cup).
Blackwell (red cup).
Campanelle jonquils (rugulosis variety).
Emperor (yellow).
Empress (white and yellow).
Lady Margaret Boscawen (white and yellow).
Mme. de Graaff (creamy white).
Norah Pearson (pale yellow and white).
Sir Watkin (yellow).
Virgil (a poet).
*Lucifer (red cup).
*Whitewell (orange and white).

(* If the soil is light.)

TWELVE VARIETIES FOR POTS.

Almira (improved ornatus).
Admiration (bunch flowered).
Aspasia (bunch flowered).
Cervantes (pale yellow).
Firebrand (red cup).
Golden Spur (deep yellow).
King Alfred (rich yellow).
Lady Moore (red edge).
Lucifer (red cup).
Orange Blossom (bunch-flowered)
Weardale Perfection (yellow and white).
W. P. Milner (nearly white under glass).
(*Note.*—Under glass, red cups and red edges do not burn, as a rule.)

ORNITHOGALUM (STAR OF BETHLEHEM).

nutans (silvery grey).
umbellatum (white).

SCILLA (SQUILL).

sibirica (blue).
sibirica alba (white).

SCILLA (WOOD HYACINTHS).

The nomenclature is confused. Some prefer the nutans—the shepherd's crook type of spike—others the hispanica, candelabra-shaped spike.

hispanica alba maxima (white).
hispanica Blue Queen (blue).
hispanica Rose Queen (pink).
nutans alba major (white).

BULBS FOR THE GREENHOUSE

How to Succeed with Bulb Growing Under Glass

WITH most greenhouses there will be a gap in the flower supply from the beginning of the New Year till stocks, schizanthus, cinerarias, primulas, etc., take up the running towards the end of February and early March. This void, however can be adequately filled with a proper selection of bulbs, and, fortunately, there is ample material from which to choose. To be successful a few cultural details must be observed, and the principal factor is to pot early so that each receptacle contains plenty of roots before the bulbs are brought into the greenhouse.

Early September is a good time to pot up hyacinths, early narcissi, early tulips and Iris tingitana; while the end of August is recommended for freesias. The rooting medium consists of sweet wholesome loam 3 parts, and 1 part leaf-mould, to which is added a little sharp sand to render the whole porous. The pots should be clean, and a few broken potsherds placed in the bottom of each for drainage.

Potting up bulbs is really a simple operation, and in the illustration can be seen a pot of freesias and one of narcissus which will be complete when each pot is filled with soil. The soil is made fairly firm, and brought up to a level so that the tops of the bulbs are just covered. Having placed the bulbs in position, the compost is pressed well between the bulbs with the fingers, and not unduly firmed immediately over their tops. Pots 5ins., 6ins. and 7ins. in diameter are suitable; but where bulbs are plentiful and a quantity of cut flower is required, boxes 6ins. or 8ins. in depth can be utilised. The bulbs of freesias are small, and for this reason many beginners overcrowd them, and, in consequence, the flowers are on the small side. Ten to fifteen bulbs are ample for a 5in. or 6in. pot, and after the potting operation is completed they should be stood in a cold frame and kept shaded until growth appears. At this stage admit plenty of air, keep the roots moist, and do not overcrowd, thus promoting sturdy growth. Here they will remain until space can be found for them on a shelf in the greenhouse; but protection from frost is necessary. Iris tingitana is afforded similar treatment. Narcissi, tulips and hyacinths should be placed in a convenient spot outside, duly labelled, and then covered with old, well seasoned ashes to a depth of 3ins. or 4ins. Periodical examination must be made after five or six weeks, and those showing signs of growth should be removed to a cold frame and shaded for a few days, or the tops of the leaves will probably turn yellow. The pots will be well filled with roots, and from now onwards they must not suffer from lack of moisture, otherwise the flower buds will fail. Early in November the first batch is placed in the greenhouse, and if others follow at intervals of a fortnight a supply of bloom will be kept up until flowers appear outside.

Among those suitable for early work will be found the Roman hyacinths, but, unfortunately, these are expensive; happily, a fairly good substitute can be obtained in the specially prepared miniature or Cynthella hyacinths, and these may be had in various shades of blue, red and pink; but the pure white variety is excellent for Christmas decoration. Moreover, it is one of the most satisfactory.

A general favourite for early forcing is Narcissus Paper White, a bunch-flowered variety often seen in florists' shops; and among the trumpet daffodils are Golden Spur, a beautiful clear yellow; and Cervantes, a sulphur yellow.

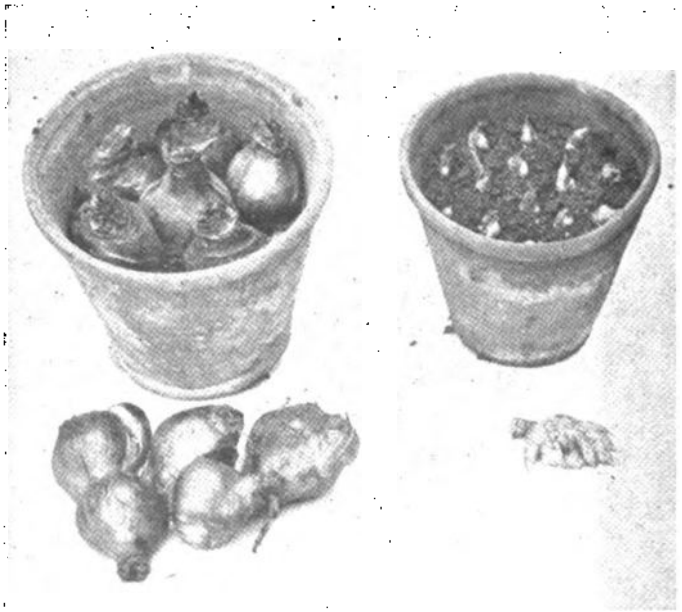
In tulips we have the Duc Van Thol varieties, and Pottebakker, pure white; also Iris tingitana; while a few pans of snowdrops, such as Galanthus Elwesii, would also be very effective.

When we come to making a selection to follow the above, we have many more varieties from which to make our choice, and almost any of the hyacinths are suitable.

For general work I have found the following narcissi give excellent results: Emperor, a large yellow fine flower, is one that cannot be left out, and it deserves to be grown in quantity because it gives such a grand display and is excellent for the garden the following year. The rich golden yellow King Alfred is more expensive, but a few potfuls should certainly be included; and the white and yellow Empress adds a little variety. In the Barrii section is Barrii conspicuus, a popular form with a soft yellow perianth and orange-scarlet edged cup. Among the star or chalice-cupped narcissi will be found Sir Watkin, the Welsh Giant Daffodil, Lulworth, and Lucifer, which has a white perianth and an intense orange red cup. This is a most pleasing variety for pots. For those who like it the old double golden yellow daffodil is recommended; I always grow a small batch.

From time to time I have tried a number of tulips for pots and boxes, and Prince of Austria is one that has proved its worth year after year. It is showy, a beautiful large copper orange scarlet, and sweetly scented. Keizerskroon is another favourite, with its scarlet and gold flowers; while of the double-flowered varieties Tournesol, a rich scarlet bordered with golden yellow, is hard to beat.

The above selection is, no doubt, open to criticism, but the object of this note is to give the beginner a good show at a small cost. With the exception of N. King Alfred, all are cheap as bulbs go, and they are easily grown. It is not advisable for the novice to begin with expensive varieties, and in many instances they would not afford the same amount of pleasure as a good potful of Emperor. B.



HOW TO POT NARCISSUS AND FREESIA BULBS.
A start should be made at once.

PLANTS FOR A NARROW BORDER

It is often a problem how to fill a long narrow border. Here are a few plants that will succeed and look well in such a position.

IN selecting plants for a narrow border—that is to say, one not more than 3ft. in width, care should be taken to choose as far as possible those of a fairly compact habit, excluding all of straggling or ultra-rampant growth, especially those with running or stoloniferous roots, as have many of the Michaelmas daisies. Such narrow borders are often found in small town or suburban gardens, and here they are frequently backed by a wall or fence 4ft. or 5ft. high, against which wall shrubs, not too vigorous of growth, should be entirely informal, and groups of lilies—candidum, croceum and chalcedonicum, for instance—and montbretias may be here and there allowed to fill almost the whole width of the border. Excellent plants for the back portion of the border are delphiniums, not the 6ft. and 7ft. giants, but Capri, Lamartine, J. S. Brunton, Mrs. Thomson and others of the Belladonna strain, none of which exceeds a height of 4ft. to 4½ft.; the dwarfer varieties of Chrysanthemum maximum (Winnie Stokes Mesagrande (deep violet) and Pink Pearl are, perhaps, the prettiest.

If possible, a narrow border should be sufficiently raised to allow of an edging of rockery stones, over which may be grown an infinite variety of charming trailing plants, including such good things as aubrietias; Veronicas repens, prostrata and rupestris; Campanulas garganica, pusilla and others; Arenaria montana; Dianthus cæsius and D. deltoides; Phlox subulata and Hypericum reptans. If the border cannot be raised, it

A SMALL NARROW BORDER IN WHICH THERE IS A SKILLED COMBINATION OF HERBACEOUS PERENNIALS, BULBOUS PLANTS AND A BACKGROUND OF SHRUBS. SUCH A BORDER WILL PROVIDE COLOUR OVER A LONG PERIOD.

can be grown with good effect. The escallonias, especially macrantha, langleyensis and montevidensis; Cotoneaster macrantha and C. horizontalis; Cratægus Pyracantha Lalandei; Cydonia japonica and C. Maulei; Ribes speciosum (syn. fuchsioides); the single and double kerrias, and the less familiar white-flowered Rhodotypos kerrioides are among the best for the position; but all will need to be kept well within bounds. A hedge, especially if of some greedy evergreen such as privet, is not desirable at the back of a narrow border, but where it exists it may be enlivened by growing climbers on poles immediately in front of it. Roses occupy over-much space, but clematises of the Jackmanni and lanuginosa sections, which can be cut hard back every year, are suitable; and Lathyrus latifolius, the everlasting pea, in its white, pink and grandiflora varieties, may be grown either on poles or on bamboo canes laced together in threes or fours with string.

A 3ft. border will afford ample room for two nominal rows of plants exclusive of any used for edging, but their arrangement is a good one); Lychnis chalcedonicum; Campanulas latiloba, latifolia and lactiflora; Sidalceas candida and Sussex Beauty (pink); Anemone japonica; Achillea millifolium Cerise Queen; Lupinus polyphyllus (hybrids of various colours); Aconitum Fischerii; Echinops Ritro; the new hybrid Eryngium Violetta, which is a fine violet blue; and Phlox decussata in variety.

For the next division of the border there is a large choice of plants of the right height—that is to say, from 1½ft. to 2ft. Here is a list of a few of the most desirable: Veronica spicata (the blue type is better than the pink or white varieties); long-spurred aquilegias; Helenium pumilum; Campanulas persicifolia and trachelium; trollius hybrids (unless the border is very dry); Anthemis tinctoria Canary Bird; Geum Mrs. Bradshaw and G. Lady Stratheden; Malva moschata and M. m. alba; and asters of the Amellus class, especially King George and Beauty of Ronsdorff. Dwarf erigerons are quite suitable, and of these Elsie (lilac), Quakeress (rosy lavender), Asa Gray (apricot yellow), is best, on the whole, to avoid a straight one-plant edging, which seems to accentuate its narrowness, substituting for this a series of clumps of well chosen plants that do not grow more than 9ins. to 12ins. tall. Within this category come Viola cornuta (purple and white), Polygonum affine; Geranium grandiflorum; Platycodon Mariesii (the Chinese bellflower); and the old fringed pink. When, however, all the plants in the border have become well established and made good growth, it is possible there may not be room for this third "row," in which case a straight edging will be unavoidable, and for it nothing will be more suitable than either forget-me-nots or double daisies for spring effect, and Alyssum maritimum Little Dorrit for summer flowering.

Bulbs that throw up a great quantity of leaves—such as crocuses and daffodils—are scarcely desirable in so limited a space; but tulips may be planted freely. Spanish irises may also be freely introduced, and spaces near the edge of the border filled with scillas and chionodoxas. R. E. H.

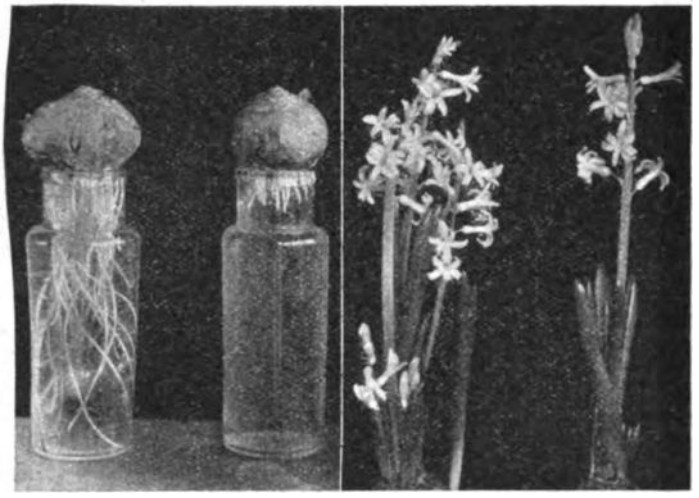
THE BUSY MAN'S PAGE

Root Bulbs Well.

WHETHER bulbs are grown in water, soil or fibre, it is most important that they should be given a chance to make plenty of roots before the top shoots are encouraged to grow to any extent. The best plan is to keep the bulbs in some rather dark place for a few weeks at the start. The illustrations show how much better is the development of Roman hyacinths when these are allowed to develop plenty of roots before being brought into the light.



BULBS SHOULD ALWAYS BE WELL ROOTED BEFORE BRINGING THEM INTO THE LIGHT.

THE DIFFERENCE BETWEEN WELL ROOTED AND NON-ROOTED BULBS.

Planting Christmas Roses.

CHRISTMAS roses should be planted in a sheltered position that is cool and moist, and where partial shade could be afforded the plants. A favoured situation is among ferns and other low-growing plants or on the margins of shrubberies away from the roots of shrubs, which have a tendency to exhaust the soil. Special beds are sometimes made up under a wall or hedge with a northern aspect, and the plants are put out in such a way that they can be easily protected by cold frames and handlights. The Christmas rose thrives much better when the quarters are deeply dug and properly drained, and the soil that suits this subject very well comprises a deep, rich loam, with which should be incorporated quite freely well rotted manure and leaf-mould. When planting in borders that are margins to shrubberies, take care to dig deeply, and in poor, light soils work a heavy dressing of cow-manure in the bottom spit.

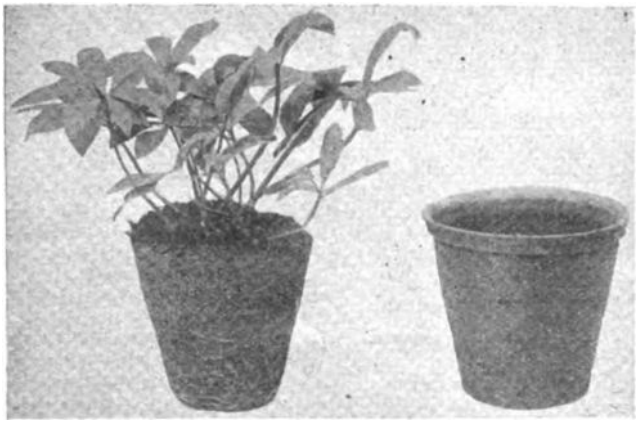
When to plant the Christmas rose is a much-vexed question. Some growers are strongly in favour of planting in February or March, directly after flowering has ceased. Other most successful growers—and these are in the majority—are strong advocates of planting in late August and September, after the plants have finished their growth. The hellebores are impatient of removal; the roots resent being disturbed. For this reason, therefore, these plants should never be lifted unless they are old and impoverished or wanted for dividing into numerous pieces. It is not at all an uncommon experience to be able to obtain from the specialists small plants in pots. This is a great advantage, as it enables the would-be grower to plant his Christmas roses with the sure prospect of the ultimate issue being quite satisfactory. In Fig. 1 a capital specimen for planting out at the present time is shown. Such a plant many growers would divide into three pieces, but, if quick results were desired, it could be planted whole. During the summer—in fact, since it flowered last winter—the plant in its pot has been plunged in a bed of ashes; this has maintained the roots and soil in a cool, moist condition. The plant has been turned out of its pot, in order to show the thick, fleshy character of the roots. When plants are lifted and divided, each piece should contain several crowns. Small plants that have three or four leaves should be planted 1ft. asunder, and larger plants should be spaced out correspondingly. Pieces about 6ins. in diameter are a very good size for planting. Fig. 2 depicts the same plant as represented in Fig. 1, planted in position. The reader will note the crowns visible in this plant, which, of course, denote promise for the flowering period.

Potting Lachenalias.

IT is time now that these interesting winter-flowering bulbs were potted. A suitable compost is two parts loam, one part leaf-mould, and half part well decayed manure and sand. Half a dozen bulbs will be sufficient for a 5in. pot placed half an inch deep, or, if the variety is expensive, one bulb in a 3in. pot will make a good pecimen. Half-pots are generally used instead of flowerpots, as these show the plants off to more advantage. Place the pots in a cold frame, give very little water and shade until growth commences. On the approach of frost place in a temperature of 45° to 50°, and when the flower-spikes appear give weak liquid manure occasionally. The lower the temperature the stronger the foliage will be. Some good varieties are Nelsoni, bicolor, pendula, Rosemary, Bullfinch and Grain. These can be obtained on the average from 8s. to 12s. a dozen.

Sow Winter-Flowering Stocks Now.

THE winter-flowering stocks are fine plants for indoors during the barren months of the year, and, if the grower takes care to choose the correct varieties, he has little trouble in getting a delightful show of sweet-scented flowers. Snow White, White Riviera, Market, and the perpetual-flowering variety All the Year Round are good whites. Empress Elizabeth, Parma Violet, Christmas Pink, Yellow Prince, Pink Beauty and other tints are also to be had. If seed has not yet been sown, then get it in at once, filling boxes with a sandy loam such as is in general use inside. As soon as the seedlings can be handled, carefully transplant them in threes into a 4½in. pot, the compost now consisting of one part in three of decayed manure, sand and mortar rubble. Keep the plants in the frame and water with care after transplanting, until growth starts again. In October take the plants inside, place on a sunny shelf near the glass, but in a cool greenhouse, and feed as soon as flowers begin to appear. As it is somewhat late to sow seed, intending growers should make efforts to obtain seedlings, as far as they can.



THE CHRISTMAS ROSE.

A suitable subject for planting now after the plants have finished growth. They should not be greatly disturbed when transplanting.

CHRISTMAS ROSES PLANTED IN POSITION.

These plants succeed under the half shade of tall trees, but should be protected from winter wet.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Garden Ornaments.

ONE of the features in garden planning in which the novice can easily make mistakes, is in the placing of stone ornaments in the garden. Here is a picture of a garden in which a sundial has been successfully introduced. Its setting, amid the stone flags of the pathway, raised a little on square slabs of stone, is just right. One passes the sundial on the way to the arbour in the corner. Stonecrops peeping from the crevices at the base of the sundial add to the suggestion of an old world garden.

For the small garden, I doubt if there is a more fitting ornament than a sundial. It does not fall into the class of "useless" ornaments, and the base forms a home for many such dwarf plants as creeping thyme, thrift and stonecrops.

A SUNDIAL IS ONE OF THE BEST OF ORNAMENTS FOR THE TOWN GARDEN IF IT IS SUITABLY PLACED WITH REGARD TO ITS SURROUNDINGS.

Thin Out Climbing Roses.

MOST of the strong-growing cluster-flowered climbers, like American Pillar, Crimson Rambler, Blush Rambler and Dorothy Perkins, are best thinned when the flowering season is over. If plenty of young growth has risen from the base, cut clean away all the old flowering wood. Great care must be exercised in doing this operation as the tips of the young, vigorous shoots are very tender and are easily broken. A good plan is to tether the young shoots to one side, away from the old wood and when the latter has been cut away it is easy to tie in the young shoots. Use fairly stout string for tying, as it will have to last twelve months. Raffia is useless as a permanent tie.

Having summer-pruned climbing roses in this way, a stimulant is advisable. A few ounces of one of the prepared fertilisers, that are frequently advertised in this journal, should be sprinkled on the soil round the base of the plant, and hoed in, taking care not to damage the roots.

Success with Bulbs in Bowls.

THE practice of growing bulbs in ornamental bowls, with the use of peat fibre, is happily on the increase. This is understandable, as, in addition to the added beauty of pretty bowls, there is less need for watering, and as there is no drainage to the bowls, there is less risk of spilt water.

Peat fibre mixture can be bought ready for use at any local florists for a small sum. This contains ground shell, charcoal, and special fertilising ingredients. A peck would be sufficient for several large-sized bowls.

Daffodils and hyacinths are the easiest bulbs to grow in this way, and I would recommend beginners to try them first, as there is much more likelihood of failure with such things as tulips or freesias. The first batch may be planted now, and the second a couple of weeks later, so that they flower in succession. Hyacinths bloom first, and daffodils are slower.

Any sort of glazed pot, bowl or vase can be used, and there is no fear of the fibre damaging the bowls. Use the fibre damp, and fill the bowls three-parts full, pressing the fibre down firmly. Press the bulbs firmly into the fibre until they are three-parts covered, and then sprinkle a little more fibre round them. Plant close together, but do not allow the bulbs to touch each other. Water thoroughly, holding the bowl on one side to allow surplus moisture to drain away.

Stand the bowls in a cupboard, or plunge them under the fine coal ashes out of doors. Air is necessary, and if a closed cupboard is used, leave the door slightly open. Keep cool, airy, moist and dark, until the top growth commences. Remove into the light gradually, and water sparingly until leaves and flowers are developing well.

When the flowers appear, place the bowls in the full light of the window but still in a cool, airy room.

Best Varieties.

Among the single daffodils, Golden Spur, Emperor, King Alfred and Sir Watkin are all easy to grow indoors. Van Sion is an old double kind and a certain bloomer. Of pot hyacinths, La Victoire (crimson), Moreno (waxy pink), L'Innocence (white), King of the Blues, and City of Haarlem (yellow) are good for bowls and pots.

Very early flowers, such as crocuses and snowdrops, may be grown indoors, but unless they can be kept very cool, failure will result. Never try to bring them on by putting them in a warm, dry room. Buy them for indoor culture in single colours—yellow, purple, lavender or white—and keep the pots in a cool room until the flowers are well developed.

Most of the failures with tulips are due, I think, to faulty watering. If the soil becomes too dry, the plants receive a check, which is fatal to tulip culture. And the soil must not be too wet, either; a happy medium is required. Pottebakker (white) and Keizerskroon (red and yellow) are two useful varieties of tulips for pot culture.

Scillas, anemones, grape hyacinths and Spanish irises can also be grown in peat fibre, and make a change from the more common flowers, but they are not so sure to succeed as are hyacinths and daffodils.

EVEN A SMALL LAWN IS A GREAT ASSET IN A TOWN GARDEN.

NOTES ON THE FLOWER GARDEN

A Decorative Honeysuckle for Covering a Wall.

Lonicera tragophylla.

THIS beautiful honeysuckle was first described from material sent to Kew by Dr. A. Henry. It was afterwards introduced by the late Messrs. James Veitch and Sons, through their collector, Mr. E. H. Wilson, who discovered it in Hupeh, West China, where it is found at elevations of 4,000ft. to 7,000ft. and 8,000ft. According to Wilson it is known to the Chinese as the Ta-chin-yin-hua (great gold and silver flower). It first flowered in the Coombe Wood Nursery in 1904. Its large golden yellow flowers, which are freely produced—as the illustration shows—place it in the first rank of known loniceras, and when it first flowered it was acclaimed as a valuable addition to our gardens, and one which would soon be generally cultivated. This, unfortunately, is not the case, for, so far as the writer knows, it is by no means common in cultivation at the present-day.

This is due, no doubt, to the fact that its cultural conditions are not properly understood, for it grows freely in any good garden soil, but the important point in its successful cultivation is that it must be grown in a position where it gets partial shade. The plant in the illustration is growing on a north-west wall, its roots shaded with shrubs and, in the writer's experience, L. tragophylla should generally succeed in such a position or on a wall facing east. Another reason why this plant is scarce may be due to the fact that its propagation is by no means easy, and it has to be increased by means of layers. It is, however, such a beautiful species, that it is worth some trouble to keep and try to cultivate successfully.—I. C.

A DECORATIVE HONEYSUCKLE FOR GROWING AGAINST A WALL, LONICERA TRAGOPHYLLA.

Marguerites for the Winter.

AT this time of year many marguerites will have finished flowering; these, if cut back now, will afford an abundance of cuttings which will supply flowers for the autumn and winter months. Plants cut back should be kept in a dry state until they commence to break out into new growth, and when a start has been made repot them. In taking the plants up out of the border the roots should be trimmed so that when they are potted up there is a fair amount of space in the pots for the plants to grow without soon becoming pot-bound.

The plants should be given a good watering after potting, then afterwards only the surface kept moist when necessary. Carefully keep the plants in check by occasional stopping, and any that show signs of flowering early should be stopped back below the flowering-stem. When the plants have become established repot them into their flowering pots without delay in a compost of two parts maiden loam, one part leaf-soil and half a part sand. Pot moderately firm, and after potting and watering the plants, stand them out in a sunny position on an ash bottom if possible.

One of the most important items in cultivating these plants is keeping them free from insect pests. A useful insecticide, which is quite simple to make, is a wineglassful of paraffin to four gallons of water. As soon as the leaf maggot or other insects are noticed, the plants should be sprayed. The sprayer I prefer is a nozzle syringe, and spread a fine spray with the finger. If this operation is done once a fortnight, there will be no trouble with any form of insect pest, and if the plants are kept clean to start with, syringing with this mixture once every two or three weeks will keep the pests at bay. The best time for syringing is either in the evening when the sun is setting or on a dull day, but on no account while the bright sun is upon them, as this causes the leaves to blister. When the autumn frosts appear remove the plants into a light, airy greenhouse, and if given cool treatment at first and a little heat later on as the nights become cold they will make headway.

Marguerites are useful to grow either for cutting or as pot plants, and if mixed with chrysanthemums have a charming effect when used for table decoration.—G. B.

Trolliuses as Adjuncts to May-Flowering Tulips.

EVERY autumn one meets with people who, desirous of making their gardens beautiful in spring, plant bulbs of tulips. Some show a preference for the stately Darwins, while others evince an interest in the old cottage sorts.

In the Darwins proper, we have, as yet, no yellow, and so Inglescombe Yellow of the cottage section is planted which, generally speaking, blooms in a little later.

Where a clump of bright yellow flowers is desired, which appear simultaneously with the Darwins, I have found that trolliuses meet the case, and for years now I have, at the back of a border where tulips are planted, a row of T. europæus which always gives a prodigality of lemon yellow flowers in May. I wonder that lovers of yellow flowers do not grow more of the trolliuses, which can now be had in a variety of tints of yellow and orange. The plants are quite hardy, will grow in almost any garden, can be divided frequently, and never fail to flower, more especially if a few weeks before the buds make headway, the plants are mulched with old manure, and given abundance of water should the season prove dry. I would remind any interested that the clumps may be shifted in the autumn, and, planted in good ground, will bloom next spring, especially if care is taken to get the clumps up without injury to the roots. Trolliuses associate well with tulips, and with me, bloom in advance of that useful cottage sort mentioned.—W. F.

The Azure Sage.

Perovskia atriplicifolia.

DURING August and September, this charming shrubby plant will make a fine show in the garden, and it can be planted in various positions, providing the situation is one where the sun shines for most of the day. It is a deciduous and rather uncommon subject with fragrant grey foliage, and it will attain a height of 3ft. to 5ft. The growth, however, dies back considerably in winter, and even so, this is no disadvantage, because to produce the best flowering shoots the plant must be cut back to within a few inches of its base early in April. Examples treated in this way are now in full bloom, the light and elegant loose growths bearing panicles of beautiful violet-blue flowers. The whole inflorescence is covered with a white meal or farina, a condition which renders the whole plant most attractive. The azure sage is well adapted for the border, the shrubbery and rock garden. At Castleford, Chepstow, it is used effectively in close proximity to boulders on the outskirts of the rock garden. Here several plants are grouped together, and it will succeed in any ordinary loamy soil.

It can be increased by cuttings in July and August, and it is possible to lift and divide old plants in the spring. P. atriplicifolia is a native of the Himalayas and Afghanistan, where it is found in quantity.—T. W. B.

Orange Sunflowers in the Border.

FOR creating a bold display in the herbaceous border during July and August, the heliopsis or orange sunflowers can be strongly recommended, and it is surprising that they are not more frequently met with in gardens. They somewhat resemble the sunflowers or various species of helianthus, being hardy herbaceous perennials and plants that will thrive in almost any soil, providing the situation is an open one.

In H. Pitcheriana we have a fine bushy plant about 2ft. or 3ft. high, which produces a wealth of deep rich orange flowers 2 ins. or so in diameter. Heliopsis B. Ladhams is another useful subject, very similar to the preceding, but the flowers are slightly larger, the petals being more or less rounded instead of flat, and the colour a little paler yellow. Both these plants are worthy of a place in the border; they are more graceful than the average sunflower and are very effective in a cut state. Another point in their favour is they are not so rampant as the helianthus, and they can be safely left for

Digitized by Google

three or four years without being lifted and divided, a fact which renders them quite suitable for the small garden.—B.

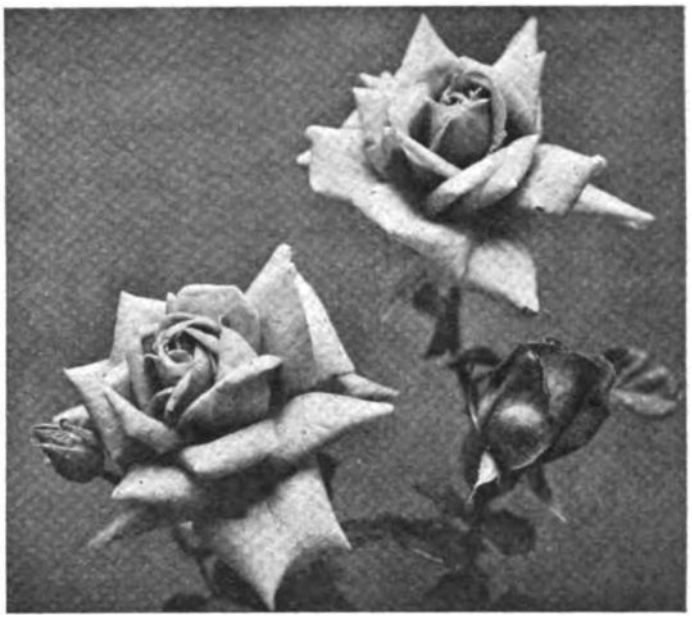
Gaillardia The King.

THE florists' varieties of gaillardia, or the blanket flower, constitute a fine and wonderful series of hardy plants for a sunny border, and, moreover, they are easily grown and very free flowering. The form named The King is certainly the best with which I am acquainted, and for several weeks it has given a glorious display; while, judging from the growth of the plants, a supply of bloom will be kept up until frosts put an end to the flowering period for this season. The whole plant is about 2ft. to 2½ft. high, and individual flowers carried on stout, long stems are about 4½ins. in diameter. The showy, broad petals are deep red, margined with bright yellow, and in a group in the border they are very effective, while in a cut state they are highly appreciated. No doubt young plants give the best results, and from a batch of cuttings rooted last September, the flowers are much better than from old plants left undisturbed from the previous year. The side growths that appear at the base of the plant make excellent cuttings, and these will readily form roots in a cold frame or in a partially shaded border in the garden. They should be transferred to their flowering quarters in early spring.—T. W. B.

Two Uncommon Roses.

MOST of our popular roses are raised in France and in England, but there are a few very good ones of German origin like the well known Kaiserin Auguste Victoria, which Peter Lambert brought forward in 1891. I should like, however, to draw attention to two newer varieties which seem to be of universal merit. One is a hybrid tea raised in 1917 by the late Dr. Krüger and called Freiburg II. It is a very good bedding rose of rather vigorous growth. The beautiful shape of the flowers is well shown in the illustration. The colour is that of a peach blossom with deeper shades of the same colour on the reverse of the petals. The petals are of good substance, opening well in all weathers. The dark green foliage is very resistant against mildew.

The other rose shown in the second illustration is a very different one, belonging to the class now called Pernetiana (Austrian briar hybrids). It was raised by W. Kordes Söhne at Sparrieshoop, Holstein, in 1921. The colour of its fine-shaped flowers is very difficult to describe. It is sometimes an almost golden yellow, edged with coppery yellow, but mostly there is a rather distinct veining and splashing of carmine in it. The colour is rather changeable, according to the season, and probably, too, according to the location. Nevertheless, the beauty of the rose is surprising wherever it may be grown. It is certainly a very attractive combination of colours even among this group of strangely coloured roses. It grows very freely and forms good, upright bushes, well adapted for bedding and for garden decoration. The blooms are freely produced throughout the season, and also valuable for cutting purposes.—C. S.



A NEW GOLDEN YELLOW PERNETIANA ROSE, SUITABLE FOR BEDDING PURPOSES.

Two Beautiful Pentstemons.

PENTSTEMON HETEROPHYLLUS is a variable plant, and in its best form, with flowers of clear steely blue colouring, it is exquisitely pretty. It is well placed high up on the rock garden, where a colony of appreciable size will prove a noteworthy feature throughout the greater part of the summer. The plant is not at all fastidious, but displays a preference, I think, for a well drained soil in full sunshine and does not object to a very dry situation. Some 18ins. high, P. heterophyllus was introduced from western North America as long ago as 1834. Propagation is by cuttings inserted in a cold frame during the summer months.

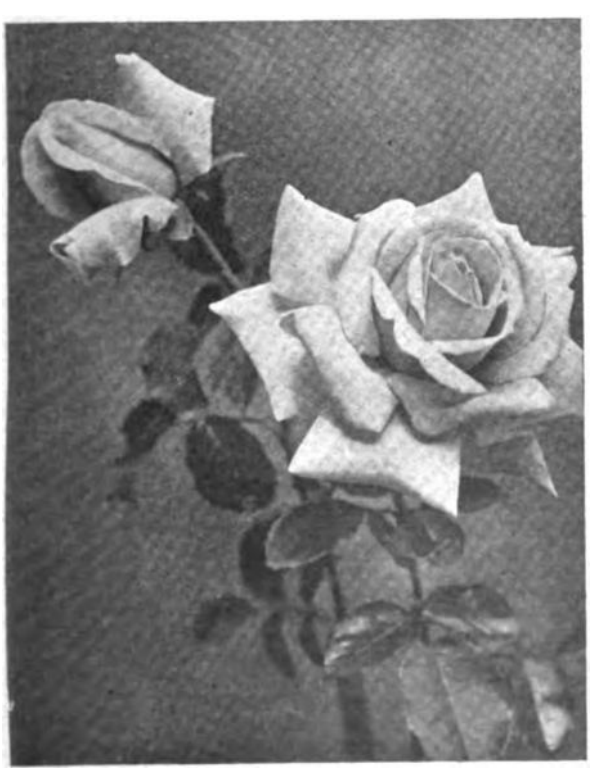
A very different plant and one equally lovely is P. isophyllus, with glaucous foliage and tall graceful spikes of salmon-coloured flowers; I was recently much captivated by the beauty of this pentstemon as seen growing in narrow borders on either side of a paved walk.

The flower spikes are from 2ft. to 3ft. in height, and are ideal for decorative purposes. A most valuable attribute of this plant is its extremely long flowering season. The first flowers will usually open during July, and in a normal season the plants will continue to make a brave display into November, providing the spent flowers are removed with some regularity.

Cuttings form a ready means of increase, and, indeed, very few plants root with greater freedom than does this very pretty pentstemon.

The plants should be generously massed to afford an opportunity of envisaging the real capabilities of this first-rate border subject. Pentstemon isophyllus may also be used to great advantage on the large rock garden.

Both these plants are hardy in most parts of the country in any but abnormal winters. It is wise, however, as with so many other plants, to maintain a small stock in a cold frame, and thus be not altogether at the mercy of our unfavourable winter conditions. —RALPH E. ARNOLD.



FREIBURG II, A BEAUTIFUL BEDDING VARIETY OF VIGOROUS HABIT.

A Trailing Plant for the Rockery.

Arenaria montana.

MANY are acquainted with the diminutive Arenaria balearica, but the merits of the mountain sandwort, A. montana, are not quite so well known. The genus arenaria is a large one, but few are in general cultivation, so it is pleasing to meet with at least one representative that has proved to be such a useful plant in a variety of positions. This arenaria inhabits the mountains of southern France and the highlands of Portugal and Spain, and it has proved hardy in this country over a large number of years. Of a procumbent and trailing habit, it is ideal for the rock garden, where it will be quite at home falling over the face of a large rock. If a small shrub is near at hand, this arenaria will attempt to climb, and attain a height of several feet. It is also suitable for walls, a form of gardening which is attracting considerable attention; while along the front of the flower border it can be employed with advantage.

The mountain sandwort is very floriferous during the months of May and June, and the individual pure white blossoms are about the size of a florin, the leaves being narrow and dark green. It is certainly a pretty subject at this season, and, being a good grower, it does not demand any special culture beyond a gritty root run where it is fairly well drained.

Such a delightful plant is indispensable, especially when we realise its beauty and the ease by which it can be brought to a high state of perfection. My plants do not seed freely, but it is readily increased by division in the autumn. Once it is established it flowers very freely, producing trailing masses of snow-white flowers.—T. W. B.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

THE allocation of space in a small garden is a perplexing problem to many amateurs whose ambitions extend beyond a limited collection of flowers and vegetables to the cultivation of a few popular fruits. A partial solution may be found in planting strawberries in a single row as an edging to a vegetable bed or border, an arrangement which enables cultural work and picking to be done from the path. As regards apples, a single cordon tree requires no more space than that occupied by a root of potatoes, and if the plan adopted in a Giffnork garden is followed, the owner may possess quite a good collection by planting the trees 2ft. apart on each side of the main walk, thus forming an avenue that combines the useful with the ornamental.

Wasps frequently do a lot of injury to the fruits of plum and pear trees at this season, but as they always travel in a straight line from their nests, it is seldom difficult to locate the habitat of these troublesome pests. A simple method of destroying a wasps' nest is to tie a rag round a piece of stick and after saturating it with cyanide of potassium, insert it in the entrance to the nest, which may be dug out on the following day. Care must be taken in the handling of the substance, as it is poisonous and should not be left lying about. Boiled potatoes covered with moss make a good trap for woodlice, earwigs and beetles. The traps should be examined each morning.

Although a number of proprietary weed killers are sold as non-poisonous, analysis made at the North of Scotland College at Aberdeen show that they are all more or less poisonous, the only difference between the poisonous and the non-poisonous being that the one contains arsenic and the other does not. When tsteed, a number of the arsenical preparations were quite successful in destroying the weeds, but the arsenic had the effect of making the walks black, especially at the sides where the liquid had collected. Trials are, therefore, being conducted this year with the object of eliminating the poisonous substances, and the results obtained are of interest to gardeners generally. The materials used are finely ground copper sulphate and sodium chlorate in solution, also known as weed-death. Weather conditions had not been suitable to the action of the latter, consequently it had not done so well this year, the walks being thickly covered with moss. On the other hand, copper sulphate had cleared the walk of weeds without the assistance of the hoe, but it was ascertained that when it was applied in the form of a solution it was of no use and that it was necessary to scatter the powder on the surface and allow it to be washed down by means of a shower or dew.

Potato trials form an important branch of the research work at Aberdeen College, and the experiments demonstrate the value of sprouted seed compared with unsprouted tubers. Plots of sprouted and unsprouted seed of Great Scot and Golden Wonder were planted on seven different occasions, beginning on March 1st and continuing at fortnightly intervals until June 1st, and the following figures, representing the highest yields obtained, are typical of the difference in the weight of the respective crops: Great Scot, sprouted, 18 tons 12 cwts.; unsprouted, 14 tons 16 cwts. Golden Wonder, sprouted, 18 tons 2 cwt.; unsprouted, 14 tons 1 cwt. In each case the earliest plantings were of better quality than the late plantings. Some light has also been thrown on the disputed point involving the cropping powers of whole and cut seed, and it would seem that the method of dealing with cut seed has a direct influence on production, for the trials of the past four years have proved beyond a doubt the influence of light and shade in the preparation of the seed. The lesson to be learned is that seed tubers should never be exposed to the sun when cut. Some people may be sceptical as regards the effect of that condition on the cropping results, but here are the actual figures. Seed cut in bright sunlight a few days before planting gave a yield of 12 tons 13cwts., while seed cut in the shade a few days prior to planting, produced 14 tons 19cwts. Lime has also a beneficial influence on cut seed when planted and covered up at once. Under this treatment the crop weighed 15 tons 1cwt., and came nearest to the total of 15 tons 10cwts. obtained from whole seed of a medium size. The difference between the yield of whole and cut seed is, therefore, so small that it would not be perceptible in the small quantity of potatoes grown in an average garden.

In its great productive capacity, the big vine at Kippen, a picturesque little village situated some ten miles from Stirling, has exceeded all previous records with a total of 2,394 bunches in 1927. This compares with 1,905 bunches in 1926, and brings up the output during the past twenty years to 25,901 bunches. This remarkable vine, now recognised as the largest in the world, was planted by Mr. Buchanan, thirty-six years ago, and at present covers 5,000 square feet of roof space (three houses), the longest spread of branches being 300ft. and the girth of stem 44ins. The size and enormous productive capacity of the Kippen vine are emphasised by comparison with other large vines in the country. The Kinnell vine at Auchmore Killin, ninety-five years old, has a roof area of 4,275 square feet and in its best years the average crop was 500 bunches; while the Monressa vine at Roehampton, sixty-three years old, extends over 3,584 square feet and gives a crop of 700 bunches. Although always spoken of as one of the big vines, this, in reality, is two vines with separate roots planted widely apart in the same house. The vine at Cumberland Lodge, Windsor Great Park, is 149 years old and with a roof area of 2,760 square feet the crop averages 450 bunches; and the Hampton Court vine, which has reached the old age of 159 years, is the smallest of the lot, the roof area being 2,200 square feet and the crop 200 bunches.

HOW TO LAY A GARDEN PATH

AT this season, when alterations in the garden are taking place or new gardens are being made, a few words of advice as to the construction of paths may be appropriate. Most gardens have paths of some sort, and whether they are made of cinder, gravel, crazy paving, asphalt or brick is a matter for individual taste; but no one, I think, will deny that square paving of varying sizes, from the points of view of simplicity, ease of laying and that the first cost is the last, should have first consideration when the kind of path is being decided upon. It requires nothing in the way of repairs, whereas paths constructed of gravel or cinder need periodical attention and renewal.

It is necessary to decide the position of paths before designing the remainder of the garden. Very often paths are made without any regard as to whether they link up with other features. It is not suggested that walks should be made all over the ground available, but it is very useful—and good planning—for paths to lead up to principal features of the garden. In this way delightful vistas can be obtained, and in small gardens a feeling of a much larger area is given. Paths also have a better appearance when set off with a stretch of grass on each side, either as a lawn or a narrow strip between path and border.

Actual construction depends a lot on the soil. When cinder or gravel is used it is very necessary to have a foundation of broken bricks, etc. Where the subsoil is clay, the path should be excavated to a greater depth than on light soils, and it may even be necessary to assist drainage by laying a row of land drainage pipes at each side. Care should also be taken to raise the centre of the finished path, as this will facilitate the drainage of surface water. Providing there is a subsoil of chalk or gravel, crazy paving, bricks or flagstones can be laid direct on to the soil, although it is an advantage to bed the stones or bricks in a layer of sifted cinders. This need not be more than 1in. or 1½ins. in depth.

Whatever the materials used, the procedure is more or less the same. The paths should be marked out with a line (3ft. is a suitable width for a main path), the turf cut and removed with a turfing iron. If gravel or cinders are contemplated, it will also be necessary to remove the soil to a depth of 6ins. to 9ins., which should be determined according to lightness of the soil. When the path is not being cut through grassland, boards of a suitable depth can be utilised for marking the boundaries. Turf or borders can be made up to this guide, which can be left permanently. After removing the soil, broken bricks or large clinkers will make a good foundation. These should be rammed down quite firmly to a depth of 2ins. below the surface of the finished path. Rolling after a good quantity of water has been put on the foundation will help to consolidate the path. It is necessary to have the foundation quite firm, as otherwise when the top surface is put on it would sink, and hollow places appear, which cause puddles in the finished path. Finally, constant rolling will prevent the surface from coming up when walked upon.

A comparison of the costs of a path in different material is difficult, and the figures given can only be taken as approximate ones. Much depends on the locality and

THREE STAGES IN THE MAKING OF A GARDEN PATH.

1.—*Raking and levelling the soil preparatory to laying.*

2.—*The paving stones being placed in position.*

3.—*The finished path edged with grass verges.*

how far the material has to be carted. In each case a path 50ft. long by 3ft. wide has been taken as a guide.

Flagstones are, of course, the most expensive, and cost is regulated by the quantity required, but a quotation recently obtained for 150 sq. ft. made up of an equal number of pieces 2ft. by 2ft. and 2ft. by 1ft., each 1½ins. thick, was 1s. 1d. per sq. ft., delivered. It must be remembered that the work of laying is simple and can easily be done.

Crazy paving can be purchased generally from local nurserymen for 50s. per ton delivered, and the quantity required (depending on the thickness) is approximately two tons for 150 sq. ft. Some nurserymen will undertake supplying and laying of the stone, and charge generally 7s. per sq. yd., but it must be remembered the work is more tedious compared with rectangular pieces of stone.

Asphalt is a messy procedure and should only be done when contractors can be got to estimate for the work. Cost of delivering and laying 6s. per sq. yd., but warning should be given that, unless properly carried out, the sun plays havoc with these paths and causes gaps to come which need to be filled up.

Gravel.—The cheapest of all paths so far as initial cost is concerned, but the most troublesome from the fact that weeds will continue to grow and that constant rolling must be carried on as well as an annual raking over and possibly the addition of more gravel. This is sold by the yard, generally a builder's cartful. One yard will be sufficient for 150 sq. ft., and will be about 2ins. thick. Clinker or large gravel stones must be used as foundation; these can be had for 7s. or 8s. per yard.

WHAT OUR READERS SAY

A FINE DRACÆNA.

SIR,—While on a visit to the garden at Ardengraig, Rothesay, the residence of Sir John Reid, a very keen and enthusiastic gardener, I saw a very fine specimen of Dracæna indivisa, an illustration of which accompanies this note. The plant was in full flower and the broom, one of the finest seen in Scotland, measured 4ft. in height by 3ft. in width. The accompanying illustration gives an idea of the great beauty of the plant and was taken by Sir John Reid.—J. Y., *Glasgow*.

SOME ROCKERY HINTS.

IT is unfortunate that really good rockery plants are expensive, and need special soil and conditions if they are to thrive; but they are so fascinating a tribe that no gardener can afford to ignore them.

One great favourite is the cumbrously named Lithospermum prostratum. This produces a mass of glowing deep blue flowers during the spring and early summer, and often again in the autumn. Another dainty beauty is the dwarf phlox, G. F. Wilson, with the most delicate of pale blue blossoms, and surprisingly successful results may be had from a packet of seed of Linaria alpina, a variety of toad-flax, very charming in "habit," as the garden books say, and gay with purple and orange flowerets for quite ten or twelve weeks on end. It can be grown on walls or as a rock plant, and makes a delightful border for stone-edged flower beds and pathways. Sown in February, it flowers the same year, and, if happy in its situation, it will continue to sow itself freely, thus becoming, for all practical purposes, a perennial. Another charming plant, easily grown from seed, and not nearly so well known as it deserves to be, is the dainty Leptosiphon hybridus, which produces quantities of tiny star-like flowers in the loveliest shades of pink, mauve and orange.

A FINE PLANT OF DRACÆNA INDIVISA IN FULL BLOOM.

In a new garden, of course, almost anything that will grow quickly is welcome, and particularly anything that will flourish in full sunshine and not need watering; for nearly all new gardens are lacking in shady corners. When making my rockery, I invested in some seed of Cerastium tomentosum—with its alluring second name of "Snow in Summer"—and trustingly scattered it broadcast over the bare spaces. During the first summer its tufts of silver grey foliage and white flowers made a pleasant enough showing; but the next year they had increased in size so alarmingly that it seemed as though everything within reach would be smothered out of existence. When the flowering season was over I had a busy time digging and dragging up huge masses of this too rampagious plant. Moral: Do not grow cerastium unless you have a very large rockery, and do not in any case grow it near less vigorous and more cherished rock plants.

Another thing to be looked upon dubiously by the owner of a small garden is the large

Digitized by Google

flowered perennial mesembryanthemum. I planted a small piece of this on the top of a 5ft. wall, and it has done well enough, covering a large space in one year with its fleshy green trailers, though its flowers, so far, have been rather sparse. Here it has room to hang down, and can easily be cut back when it threatens to spread too far. But another piece, planted on the low wall at the foot of the garden, has had to be, with great labour, entirely removed, for not only were its hefty 6ft. and 8ft. long trails spreading all over the flower beds alongside the wall, but they were also threatening to kill by slow strangulation several members of a cherished tamarisk hedge. Fortunately, this was discovered just in time, and the too ardent grower torn up root and branch—no easy task, as I said before—that the smothered tamarisks might have room to breathe and live, like their fellows. The dwarf mesembryanthemum, with its pretty little mauve pink flowers, is a different matter altogether, and an ornament to any rockery. But avoid the other at all costs, unless you can give it space unlimited in which to "ramp"!—FAY CORNISH.

SOUTH AFRICAN CHINCHERINCHEES FOR THE GREENHOUSE.

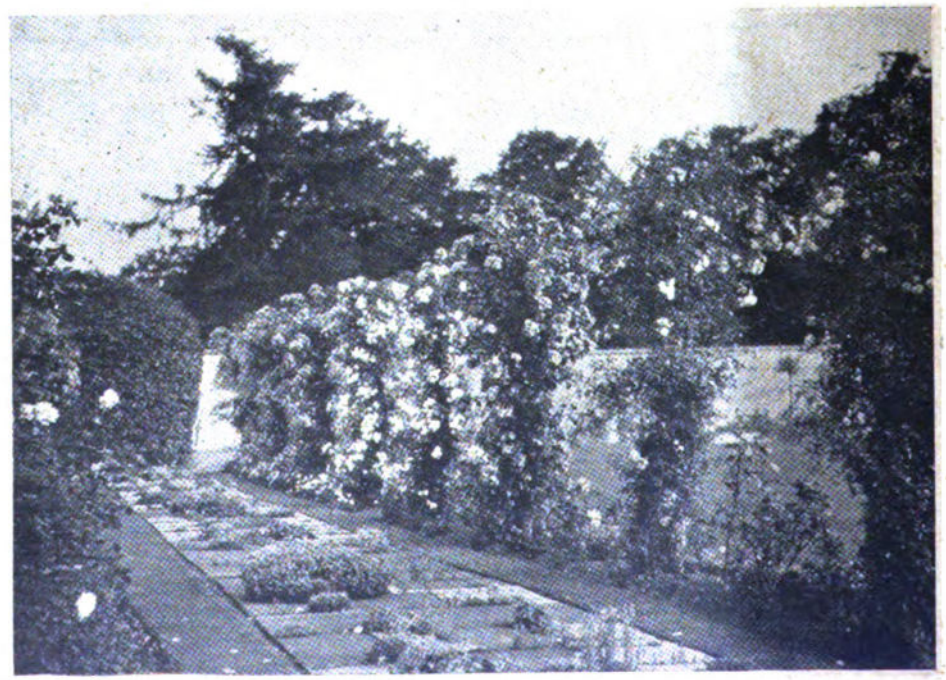
SIR,—Enclosed is a photograph of a plant of Ornithogalum lacteum, or chincherinchee, in flower in a cold greenhouse in York. It is a South African plant not often grown in this country. When the bulb was received, two years ago, it was about the size of a large snowdrop. It was grown on in ordinary cool greenhouse temperature with periods of ripening and resting, which are plainly shown by the condition of the plant. After two years of this treatment the flower-spike appeared and grew to about 2ft. 6ins., the flowers opening as the spike developed. The portion of the spike actually covered by flowers is about 12ins. At the time the photograph was taken some of the flowers had been open a month, and it will be seen that there are still a large number to expand. The flowering period is thus an unusually long one. The petals are white with delicate veinings, the yellow stamens adding a bright touch of colour. An interesting point is that after having been cut and dried the flowers have the faculty of reviving to a considerable extent when placed in water. —W. J. WALLER, *York*.

A HANDSOME FLOWER SPIKE OF ORNITHOGALUM LACTEUM.

SNAKES IN THE GARDEN.

SIR,—I have had a considerable experience of the common grass snake (and vipers) in various parts of the country and my observations do not agree with the conclusions which Mr. J. Gregory draws concerning the death of his carp. With one solitary exception all the grass snakes that I have known have swallowed their food whole. With solids this, of course, is from necessity, as the snake has no teeth for masticatory purposes, and a frog would present no difficulties to a snake. On several occasions I have killed a snake which had recently swallowed a toad and have released the toad, which, after squatting in a dazed manner for a short time, has revived sufficiently to walk away. I feel that Mr. Gregory must look elsewhere for the cause of his "half-devoured frog." With regard to the carp with a deep gash in the side of its neck, I should hesitate for a long time before attributing this to a grass snake. I have on a number of occasions watched snakes swimming in a pond which contained a number of carp of various sizes and degrees of markings, from the typical fish, through a motley of colourings, to self "gold" and "silver," and in no case has a snake made the slightest attempt to take a fish. The snake's method of progression through the water was, to me, most interesting. While undisturbed a snake would carry its head and an inch or two of body clear above the water, and so far as I could see—owing to refraction one can rarely be positive as to what happens under the surface of water—the snake would progress almost vertically, and propulsion was derived from rotary movements. On a stone being thrown into the water the snake would dive, but remain under water for only a short time. The exception which I mentioned to snakes swallowing their food whole was the case of one snake which developed a liking for grapes. On several evenings it entered the vinery soon after dusk and *sucked* the berries, leaving the skin and a portion of the flesh hanging by the stalks.—A. CECIL BARTLETT.

OUR PHOTOGRAPHIC COMPETITION



This charming Ipswich garden has its paved path bordered on either side with rose arches. Climbing roses have been planted up pillars which are linked together by means of chains, and the long rose shoots are trained along these. Each year the roses are a mass of bloom. The path is paved with square slabs of York stone, and many rock plants are growing in between the crevices of the stone.

The guinea photograph, sent in by F. G. BROOK, *2, Willoughby Road, Ipswich.*

FRUIT AND VEGETABLES

Laying-in Young Wood of Cherries.

ALL stone-fruit trees should be closely examined now, especially those on walls, and mental notes made of ways and means to improve them. Young wood is a valuable asset, that is when such wood is of normal growth—of medium strength, short-jointed and well ripened. Some old wood is generally found to be unsatisfactory, and such must be removed in due course, and, if there is not any young wood to replace it, gaps occur in old trees, whereas in the case of younger specimens young shoots are necessary for extension. Usually in the case of Morello cherries there is a danger of having too much young wood, then there is overcrowding, immaturity and a loss as regards the crop. It is for these reasons that I suggest to inexperienced growers the desirability of closely examining the trees now. Where young branches are to replace old or diseased ones, the latter should be cut out forthwith. It is useless in itself and harmful to the young shoots if retained. Young shoots to be fastened in as leaders are best shortened now one-third their length, then the basal buds will grow next year, whereas if retained their full length perhaps many basal buds may not grow, then there is a blank space, very undesirable both for appearance and waste of space, as the latter is so valuable.—CHRISTCHURCH.

Cauliflowers to Stand the Winter.

WHERE early cauliflowers are appreciated, the best, usually, are those grown from seeds sown in the month of August or early in September. Spring-raised plants require very careful treatment if they are to "turn in" satisfactorily at an early date, and usually glass protection must be afforded and very gradual must be the full exposure to the weather. Autumn-raised plants, too, require some protection during severe weather, but in a temporary form only, and such that any amateur can easily apply. In northern counties, seeds should be sown quite a fortnight earlier than in the south; in the midlands a week earlier. September 10th to 20th is a suitable time in the extreme south. In the north the seeds may be sown in boxes, as the resultant seedlings must be transplanted in any case, but I much prefer to sow them in cold frames and remove the lights entirely; in the southern counties the open border is the ideal place. A sheltered position does not mean one enclosed by high hedges, or fences, walls or trees, but where the border is protected by some low structure such as will break the force of the wind, especially that from the north and east. The best soil is a medium loam, and one in which these kinds of plants have not been previously grown. If poor, enrich it a little with some rotted manure; also in all cases, except in chalky soils, add some old mortar rubble. Make the soil very firm after digging it deeply. Sow the seeds thinly and transplant the resultant seedlings 4ins. apart in borders where a temporary protection can be given, or in cold frames. But to be successful with autumn-raised cauliflowers the plants must be grown sturdily and as hardily as possible.—GEO. GARNER.

Clean up the Asparagus Border.

AS soon as the feathery foliage of the asparagus plants begins to die down, the cleaning up of the bed may be carried out at once, often a very necessary operation, because weeds are difficult to remove in the height of the growing season. First of all, cut the stems some 3ins. from ground level and lay these aside to be burned. After this, remove all weeds in any fashion that is without danger to the asparagus roots, and carry these away too; if, in doing this, slugs are found to be present, dust the soil with fresh soot afterwards. Loosen the ground with the hoe or a Buco cultivator carefully and apply a mulch of fibrous, semi-rotted manure. As growers know, this mulch may with advantage be omitted until springtime, if the soil is a wet one. Do not forget that an old asparagus bed may be improved by liming, the best form to use being basic slag of low phosphatic content at some 4 oz. to 6 oz. per square yard. Lastly, dig the alleys, and the bed is ready for its long winter rest.—CLYDESDALE.

Autumn-Sown Broad Beans.

IT is not common practice to sow broad beans in autumn, but many growers, especially in the "kinder" districts, do it with the advantage of earlier cropping in the following summer. Should the winter be a bad one or chill storms come along in spring, there is no advantage in sowing during autumn, because plants recover slowly from a check at that time. So, having "placed our cards on the table," I now remind readers that it is time to sow these broad beans. Almost any variety may be treated in this way. Plant them 3ins. deep and a trifle closer than in spring. It is best to avoid fresh manure and, perhaps, not too wise to manure at all. When the beans are well through the ground, earth up a little; indeed, when the garden is kept too wet in winter by incessant rains and a heavy soil, place the beans on the surface level and hoe a ridge of soil over them to a depth of 3ins. or 4ins.—LANARKSHIRE.

Hardy Lettuce to Sow Now.

CERTAIN varieties of lettuce are exceptionally hardy, and they may be sown at once in the open in order to ensure supplies in winter and spring. Speaking broadly, they may be treated much like the winter endive. In colder parts, overhead protection may become necessary but, even when plants seem to dwindle away as winter advances, the advent of spring calls them into life again, and a supply of green salad is then certain. Not all varieties will do well, of course. Among Cos kinds we have long depended on Black Bath, Winter White and Veitch's Hardy White. In the cabbage varieties, Hammersmith Hardy is a good kind, as well as what is called Winter Arctic and the variety, Standwell. All the Year Round may also succeed. As it is fairly late, sow thinly in firm soil where the plants are to grow and avoid transplanting as far as possible.—H. H. A.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF-GUINEA HINT

Carnation Cuttings.

A year or so ago, when taking my cuttings, I tried an experiment. Half of the batch were planted simply as slips, the other half were treated as follows: I split the stems with a sharp knife to a length of about 2½ins., and in planting these latter a drill was drawn about 4ins. wide and 4ins. deep and filled with sharp sand. The cuttings were pressed firmly into the sand with the split stems extended so as to lie at right angles to the cutting. When the cuttings were lifted for planting in permanent quarters, those treated in the manner described possessed two roots, and the majority of these made more bushy plants and carried more blooms than those simply inserted with a heel.—A. C.

Rolling New Gravel.

To roll new gravel on a path is difficult, unless the gravel be dry or thoroughly saturated; between these extremes the roller will pick it up and a bad mess will be the result. This can easily be overcome—if the area be not too great—by spreading newspapers and rolling over them. The same method can successfully be used on a lawn, when—as is sometimes the case—a depression or bare patch is repaired by sprinkling mould and fresh seed on the top.—G. L.

Home-Saved Seeds.

Home-saved seeds are quite successful if proper care is taken and fresh seed obtained at least every three years. Seed should only be saved from strong, healthy plants. The following is a method I have found to serve well both for flower and vegetable seeds: Keep an open eye for fine well formed vegetables and flower blooms. As soon as you see these mark them with a little piece of red ribbon tied in a conspicuous place. When the seed-pods form it is best to pull some off, leaving about three or four to mature. When they are ripe and dry (on no account pick while wet, as mildew will be prevalent) pick them off and rub over a piece of white paper. Be careful to deal with one kind of seed at a time. To finish off, clear up rubbish, packet the seeds and name clearly in ink.—C. J. L. W.

Earthing-Up Celery.

The earthing-up of celery can be greatly simplified by the use of an ordinary garden line. Place one stick, with line attached, firmly in the ground at the bottom of the trench; then, keeping the line just taut, twist it once round the first stick of celery about 4ins. or 5ins. from the ground. Proceed to the next plant and repeat the operation until all the plants are secure. Finally, place the second stick in the ground. Both hands are now free to carry out the work of earthing-up quickly. When soil has been placed up to the line, this can be easily untwisted and a second operation can be commenced, if necessary, higher up the plants. A great saving of time will be effected if this method is carefully carried out.—J. G. F.

Drying Flowers for Winter Decoration.

To ensure flowers suitable for drying for winter decoration retaining their original colour when gathered or bought, bunch lightly and tie, and put, heads first, into a large paper hat-bag or pin newspaper carefully around them not to crush them; the great object is to exclude all air, so see there are no holes in the bag. Gather ends of bag or paper to the stems, tie, and make a loop and hang in rather dark dry place for a month. They will then be ready to arrange in vases. Sea lavender is a very good flower for drying in this way. Everlasting flowers (which should be gathered half-open) and honesty also answer to this treatment.—N. W.

WORK IN THE GREENHOUSE

Hydrangeas for the Amateur.

This is the time to take cuttings to increase your stock of these desirrable plants.

ONE of the greatest mistakes the amateur makes is in trying to grow too much in his small greenhouse. A much better plan would be to concentrate on one or two varieties of plants and grow these to perfection. This is by no means so difficult a matter as one might at first imagine. For instance, what could be better than a collection of up-to-date varieties of hydrangeas for next spring. In the old days one had to be content for the most part with whites and blued varieties, for let it be noted there is no blue hydrangea, only by blueing the soil or the plant by application of special material from the specialist. However, a good collection might be made by consulting the growers' lists. You may have bright carmine (Etincelant), pink (Maréchal Foch), dark rose (Helge), mauve (La Marne), red (Rubis), salmon (Krimhild) and many others. These are but a few of the various colours to be had at fairly reasonable rates from the dealers. Certain sorts are more easily blued than others, La Marne is one, Maréchal Foch another. However, the amateur may wish to produce plants from some older varieties of H. hortensis, from which all others came. This is no difficult matter, for the plants are easy to manage and are ideal for the amateur, as they require little or no heat and after a certain stage require plenty of water. In fact, they are cool-house plants. The method of growing plants with one large head of bloom is best for the small greenhouse.

How to take Cuttings.

The present is a good time for taking cuttings. These are obtained from old plants, and shoots that have not flowered are chosen, the plants having been stood outside to ripen the wood. The cuttings should have three pairs of leaves and the cut made square below a joint. Remove the bottom leaves and, above all, make the cuttings very firm in their small pots. A good soil mixture is leaf-soil, peat and loam in equal parts, and plenty of sand; where peat is not obtainable, increase the quantity of leaf-soil used. When potted to the grower's satisfaction, the plants may be placed in the cold frame and kept close until rooted. They must also be syringed twice daily, but at the same time the atmosphere of the propagating case must not be damp and stagnant. When the plants are rooted, plenty of air must be given, starting by gradually increasing the ventilation until it is possible to have the lights off altogether. Soon the plants will be ready for their final pots. Six-inch pots are a suitable size for the ordinary amateur's greenhouse.

Treatment of Plants.

After potting on, the plants are stood outside in order to ripen the wood, otherwise no flower of any worth will result. Gentle feeding may commence and the doses be increased as the plants need it. The compost for the final potting must contain a good proportion of peat. It should be peat (two), leaf (two), loam (one), with a fair amount of sand. Again, where it is not possible to obtain peat, increase the leaf-soil. Good results are to be obtained by this method, although it is better to exert oneself to get peat. Needless to say clean, well drained pots must be used. Good results are to be obtained by wintering the plants in a cold frame using some protective covering in hard weather. A better plan is to move the plants into a cool greenhouse, but there must be no great heat (in fact, only enough heat to keep out frost). When the flower buds begin to form, feeding may again commence. It is advisable to use much care in applying artificial fertilisers. Certain of these are not suitable for hydrangeas, and it is certainly worth while to purchase one of the special fertilisers from the specialists advertising in these pages.

Apply Blueing Powder Now.

At the same time, one might order some of the blueing powder which is mixed in the soil for the final potting or made to mix with water and applied to the plants in that way. By following these instructions it will be possible to have a good show of hydrangeas in the cool greenhouse next spring. When growing well, these plants must have plentiful supplies of water and for that reason are to be recommended for the amateur's greenhouse. It is on this point that so many owners of small greenhouses go wrong. A glance through a dealer's list will help the novice to select new varieties to grow. In any case, if you have never tried propagating these plants, do so this year. The present month is the time.—T. H. H.

A New Greenhouse Primula.

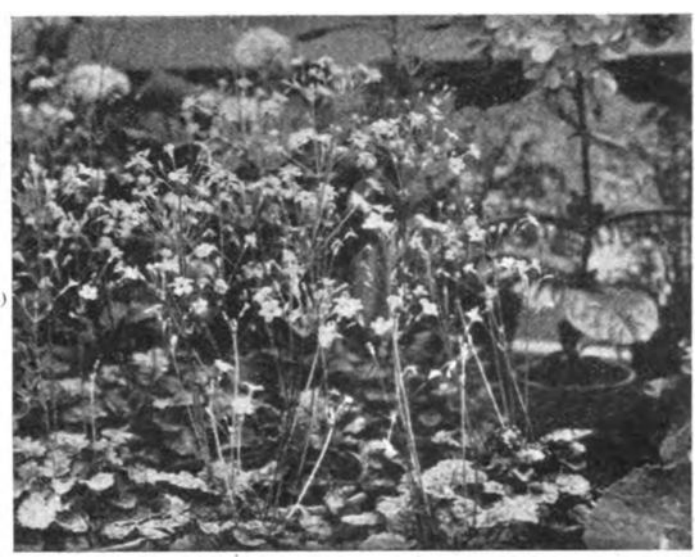
PRIMULA EFFUSA is quite a recent introduction from Yunnan, Western China, where it was discovered in 1914 by Handle-Mazzetti and Forrest. In 1922 Forrest and Ward collected it in the same neighbourhood, Fenghow. It first flowered at Kew during the spring of 1925. It is a very graceful and dainty species, which, when it is better known, should prove as popular as the older and better known P. malacoides, to which group it belongs. The illustration may give some idea of what the plant is capable of doing, A well grown plant in a 5in. pot normally produces a sheaf of its slender, graceful inflorescences. It is easily raised from seed, which may be sown towards the end of July or during August. It thrives in any good potting compost, and grows freely in an ordinary greenhouse. The young plants should be potted on as they require it until they are in 5in. pots, in which size very useful examples can be grown. It, however, likes plenty of root room, and if extra fine specimens are required, it pays to give them a final shift into 6in. pots. It lasts in flower for several months; it is also a good perennial and, if so desired, can be readily increased by division. This can be done during August after the plants have finished flowering. We have heard complaints that it is difficult to obtain seed from this plant, but by hand pollination the writer has experienced no difficulty in obtaining seed. Its flowers are of a pleasing rosy pink colour. In this respect it shows some slight variation in the colour, and although it has only been in cultivation for a few years, it has already given individuals with double flowers. In this respect it may be compared with P. malacoides, which soon gave double and different colour forms under cultivation.—J. C.

A Brilliant Greenhouse Plant.

LARGE specimens of Kalosanthes (Crassula) coccinea, surmounted with their bright coral red flowers, always attract attention, but it is not every gardener that can afford the time and space necessary to produce these large plants. The smaller specimens in 5in. pots frequently seen in florists' windows are more generally acceptable, and, where a number are grown, are certainly more useful.

Now is the time to insert cuttings, if it is desired to have these smaller plants in flower during next May or June. From old plants that have flowered, select the best of the unflowered growths. These should be well ripened and about 3ins. in length. Cut through below a joint and remove all the lower leaves. If these cuttings are left exposed to the air for a few hours before insertion, so much the better. Prepare a compost consisting of fibrous loam, three parts, one part old mortar rubble and one part sand.

Fill the required number of 5in. pots and insert the cuttings six in each pot. Stand upon a partially shaded greenhouse shelf until rooted, and then expose to full light and sunshine. Do not repot the plants, but allow them to remain until flowering time, when each plant will produce one head of bloom and these, if carefully staked out, will make very pretty specimens.



PRIMULA EFFUSA MAKES A DECORATIVE DISPLAY IN THE GREENHOUSE DURING SPRING AND SUMMER. SEED MAY BE SOWN NOW.

Be very careful not to over-water, especially during the winter months, when a temperature of 45 to 50 degrees will be the most suitable, the aim at all times being to keep plants as sturdy as possible.

The Hardy Border Carnation.

Its Value as a Pot Plant.

THE hardy border carnation, treated as a pot plant, is in many ways a more suitable subject for the amateur gardener than is the perpetual-flowering carnation. It would be difficult to find points of superiority in the latter. The border variety is, at least, equal to the perpetual-flowering carnation in size and colour, while in habit and formation of the flower it is vastly superior to its more pampered relation.

It is a common practice to accommodate the rooted layers, after lifting, in a 3½in. pot throughout the first winter. Such layers may be potted on into a 5in. pot early in the New Year, not later than March. The

Digitized by Google

carnation is averse to feeding and it is, therefore, wise to make full provision for its needs at the time of preparing the potting compost. Fresh loam, turf passed through a half-inch riddle, a liberal quantity of sifted mortar rubble or air slaked lime and a little bone dust will make a compost that will supply the plant's soil requirements, and remain sweet for a considerable time. Carnations will not thrive under acid soil conditions, and for this reason fertilisers and leaf-mould should be omitted. A handful of crocks to ensure effective drainage, and firm potting are essentials. Such a potted plant may be allowed to remain in the open, where its requirements are few, until the bud shows signs of opening, when it should be transferred to a well ventilated greenhouse. A splendid flower will be obtained if the higher lateral buds are removed. After flowering, the plant may be removed to the open again, being afforded the protection of a frame or cold house during the winter. In the following spring it may be potted on into a 7in. pot, where it will proceed to make a very free growth, making a sturdy, compact plant with as many as six flower stems. Grown in the open and carried into the house in June, the flowers produced upon such a plant will be superior to those obtained upon any other subject. The carnation is the "divine flower" the "rose without a thorn." Glorious upon the plant when graced by its own glaucous foliage, charming in the bouquet when relieved with asparagus fern, and exquisite in the vase surrounded with gypsophila, the carnation is assuredly the perfect flower, and the hardy border carnation the perfect carnation.

FRUIT BOTTLING AT HOME

Practical Hints on Preserving Your Own Fruit

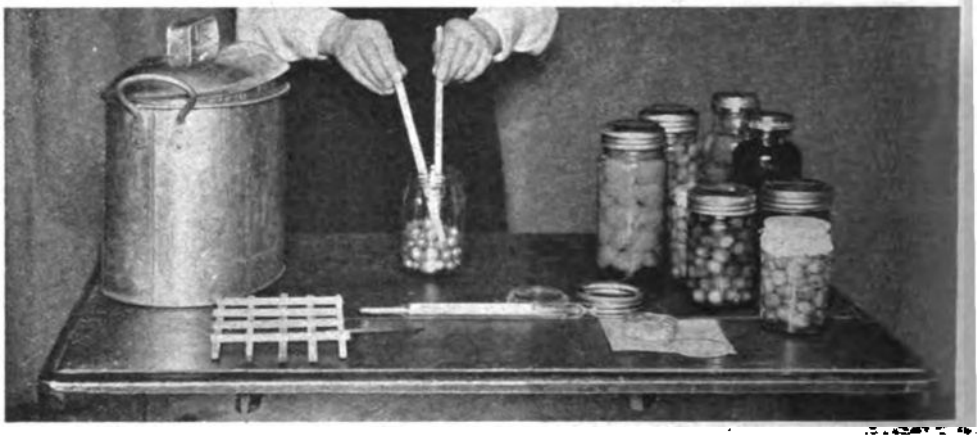
THE old housewifely art of fruit bottling has come very much to the fore in recent years, due, no doubt, to the necessity for economy and to renewed interest in preserving our own garden fruit for winter use—possibly also to the introduction of the modern "fruit sterilising apparatus."

The bottling of fruit is really quite a simple process, cleanliness and minute attention to detail being the keynotes of success. Whatever the method employed, the underlying principles are the same—(*a*) thorough sterilisation—the destruction of any germ in fruit or water, productive of mould or fermentation; (*b*) exclusion of air after sterilisation.

A Fruit Sterilising Outfit, of which there are several reliable kinds on the market, is a useful addition to the kitchen equipment, for it economises time and labour and reduces risk of failure to a minimum. The old fashioned method of bottling in ordinary jam jars and sealing with fat, parchment covers, etc., is by no means unsuccessful, but it is more laborious, and there is always just the risk of imperfect sealing.

A thermometer, which is supplied with a "fruit sterilising apparatus," is not an absolute necessity for bottling, but the use of one is an aid to success. A dairy or bath thermometer is suitable, but it is advisable to test it before use. Put it in a pan of old water with the mercury about 3ins. below the surface. When the water boils (212° Fahr.), if the thermometer registers above or below this degree, calculate accordingly when sterilising.

Substitute for Patent Steriliser.—Use an ordinary fish kettle or any pan deep enough



WHEN ONLY A LITTLE BOTTLING HAS TO BE DONE, USE CAN BE MADE OF EVERYDAY HOUSEHOLD ARTICLES.

Here a fish kettle is being used, with a home-made wooden grid to keep the bottles off the bottom of the pan. Two wooden sticks are handy for arranging the fruit in layers.

(roins.). A false bottom is indispensable. A meat rack, strips of wood tacked together lattice-fashion, or even a folded teacloth will answer the purpose. If using a thermometer, to avoid dipping it in and out, make a hole in the lid of the pan and fit into it a piece of rubber or cork with a hole pierced in the middle; this will grip the thermometer and keep it in position.

Bottles.—Bottles with glass caps, rubber bands and metal screw-down rings are largely used, and for hygienic reasons are preferable to those with a metal cap. On the cooling and contraction of the contents of the jar a partial vacuum is formed within, and this, with the outside air-pressure, fixes the lid tightly and seals it hermetically.

General Directions for Bottling.

Methods vary slightly, but general rules are applicable to all.

(1) Use perfectly clean bottles with wide necks, and pure water.

(2) Fruit must be clean, dry and sound, and should be rather under than over ripe.

(3) If graded as to size and ripeness, space in bottle is economised and fruit is equally sterilised.

(4) Prepare fruit in the usual way, wash and dry, handling and cleansing soft fruits as gently as possible to avoid crushing. Peel, core, halve or quarter apples and pears, and, to preserve colour, drop into slightly salted water as peeled.

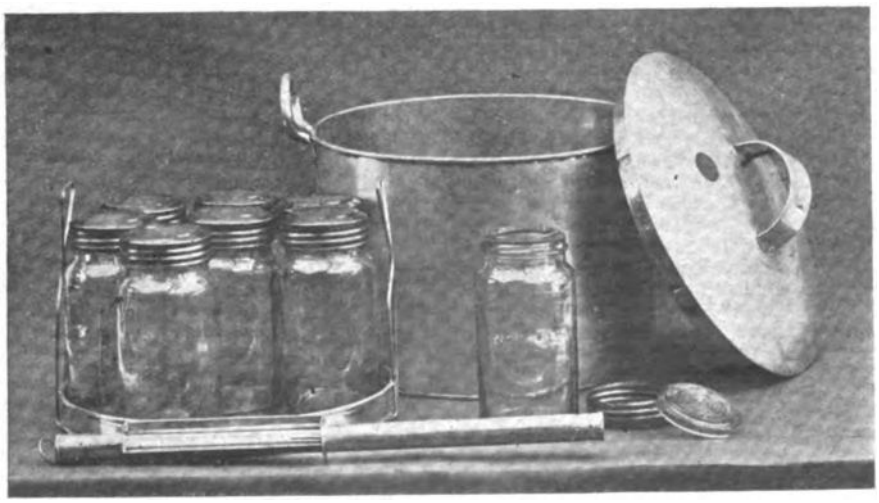
(5) *Well fill* bottles, shake the fruit down, pack tightly, but avoid crushing. Two wooden sticks (12ins. long), pointed at one end, are useful in arranging fruit in layers.

(6) Apply heat *very gradually*.

(7) Glass, being a bad conductor, heats unequally and is liable to crack upon exposure to sudden extremes of temperature; hence the use of a false bottom in the steriliser. Never put a hot bottle on a cold surface or leave it in a strong draught, nor let a cold one come into direct contact with hot metal (such as the oven shelf).

(8) *Remove one bottle at a time* from the steriliser or oven and *seal at once*, to exclude air, by which germs gain access to the fruit.

(9) Store in a cool dry place. Strong sunlight is apt to bleach the colour of fruit.



AN INEXPENSIVE STERILISING OUTFIT.

With thermometer and removable holder for the bottles, which have glass caps and a screwed metal collar.

WINTER-FLOWERING SHRUBS

MORE attention should be paid to the interesting shrubs which flower during January and February. One of the best of these is winter sweet (Chimonanthus fragrans), a native of China and Japan. This, although a bush by nature, often does better when planted against a wall. Well established plants are from 6ft. to 8ft. high, and these bear pale yellow flowers, that are very fragrant, in mid-winter. A variety known as grandiflorus produces flowers of a larger size, and these are bright gold in colour. This variety is more tender than the type and should be placed against a south or a west wall. A few flowering branches of winter sweet placed in a room are attractive to look at, and, in addition, give out a pleasant fragrance. The chimonanthus does best in a loamy soil, but it is really very accommodating. When grown as a shrub little or no pruning is needed, but if against a wall, the shoots should be cut back as soon as flowering time is over. Then the Cornelian cherry (Cornus Mas) produces yellow flowers in great abundance soon after the turn of the year. This shrub will grow well in practically any soil, but it likes rather an open situation. A place should be found for the mezereon (Daphne Mezereum) which develops its fragrant reddish flowers in February. The variety known as grandiflora is better than the type, for it bears bigger and brighter flowers and blooms at an earlier date. A white variety, alba, is good, for later on in the year this will bear yellow berries in contrast to the red berries of the two first named. The mezereon likes rather a moist position and it is always especially fine in chalky districts.

The Chinese witch hazel (Hamamelis mollis) is a very beautiful winter-flowering shrub. The plant has large oval leaves which are hairy and very distinctive, while its golden, scented flowers are distinct from those of the other witch hazels, by having flat petals instead of the twisted petals of the other kinds. The Chinese witch hazel is at its best quite early in the year. Another showy species from Japan, known as H. arborea, flowers a little later. A variety called Zuccariniana is said to blossom rather more freely than the type. All the witch hazels like a light loamy soil, and do better if a little peat is placed round about the roots. The bush honeysuckles (Lonicera fragrantissima and L. Standishii) produce cream and white coloured flowers in January and February. These are often placed against walls, but the plants grow well in shrubberies if not shaded too heavily. A moist loamy soil is the best for these bush honeysuckles. An interesting semi-evergreen plant which is in flower from December to February is Rhododendron dauricum. This is a perfectly hardy shrub with an erect habit, and it produces its rose-coloured flowers with great abundance in any district where rhododendrons can be grown.

This Week's Work

For Gardens in the South and Midlands.

Finish layering Malmaison and border carnations.

Sow seeds of antirrhinums.

Thin out old wood from rambler roses and tie in new young shoots.

Take cuttings of lobelias and verbenas.

Make sowings of onions and spinach.

Lift second-early potatoes.

Wrap haybands round trunks of apple trees in order to trap female codlin moth.

Plant St. Brigid anemones.

Sow seed of schizanthus in a cold frame or greenhouse.

Clean up strawberry beds.

Guarding Against Fungus Diseases in the Autumn.

THE present year has been productive of fungus diseases in a very bad form on various kinds of plants, fruit trees and vegetables. We should not wait till another year without taking measures to protect our garden crops from its ravages next year, as the spores live in the soil and on plants and thrive amazingly again directly suitable conditions obtain. Lime is a good preventive, and not only kills fungus spores in the soil, but improves the latter considerably. Where possible, mix lime with the soil, and freely with garden refuse in cases where the latter cannot conveniently be destroyed by fire. Sulphur is also a good agent and, properly mixed to the consistency of paint, should be in due course painted on vine rods—taking care to keep it from touching the buds or eyes—and judiciously sprinkled in a dry state on the soil of the borders and under stages, even on the hot-water pipes in vineries and peach-houses, so that fumes may be given off when the pipes are gently heated to exclude frost. But the sulphur must not be applied to the pipes in plant-houses. All dead chrysanthemum leaves should be burned forthwith, as rust and mildew often infest these. Both in the garden and glass structure absolute cleanliness should rule, then the risk from infection next year will be reduced to a minimum.

The R.H.S. Daffodil Show.

THE Royal Horticultural Society's Daffodil Show will be held next year on April 17th and 18th, and the schedule, which has recently been issued, may be had on application to the Secretary, R.H.S., Vincent Square, Westminster, S.W.1. The competitions are open to all residents in Great Britain, Ireland and the Channel Islands, whether they are fellows of the society or not, and there are no entrance fees. In addition to the open classes, there are special sections for amateurs, novices who have never won a first prize at an R.H.S. daffodil show, and market growers. In the past it has sometimes been said that there was no chance of winning a prize unless one could afford to buy the expensive new varieties, and so this year it has been stipulated in a number of classes that all the varieties exhibited must have been listed in a retail catalogue in the autumn of 1927 at a price as low as a certain specified sum. It is hoped that these classes will attract exhibitors from the ranks of those who are not daffodil specialists, but who are more or less keen admirers of the queen of spring flowers.

This Week's Work

For Gardens in Scotland and the North.

Lift maincrop onions.

Pinch tops of tomato plants in cold greenhouses.

Transplant spring cabbage.

Begin planting hyacinths and daffodils in bowls of fibre.

Take cuttings of calceolarias.

Plant new beds of strawberries.

Sever and pot up carnation layers.

Cut out old fruiting canes of loganberries.

Give wallflowers a first shift.

Continue earthing up celery.

Prepare ground for new raspberries.

Cut out old wood of rambler roses that have finished flowering.

Digitized by Google

PERENNIAL IRISES FOR PRESENT PLANTING

All Plantings of Irises should be Completed by the End of this Month.

THERE are few, if any, subjects among hardy plants which equal the iris for their possibilities in border or landscape effect or for their wonderful variations of beautiful colours. It is, indeed, a matter of great difficulty to convey a full idea of their beauty and the charm of the many varieties now in commerce. The coloured illustration on the cover of this issue is, we think, a very successful attempt to show a few of the leading varieties in their natural colouring. The hand of the hybridiser has, indeed, worked magic in the charming creations now before the public. No one did more in this respect than the late Mr. W. R. Dykes, and the wonderful results which he achieved will for ever remain exquisite evidence of his patience and skill.

Almost every shade and hue can be found beautifully blended in these gorgeous flowers, while the markings are so effective that they at once arrest attention and compel admiration. The varieties, one and all, are highly ornamental as decorative plants, and no flower improves so much on close examination. They should be extensively planted in flower and shrubbery borders and naturalised. Irises are not fastidious in their requirements, for the most part being quite as easy to grow as the familiar blue flag, which is to be found in most of the old-fashioned gardens, and flourishes so well even in the smoky atmosphere of London; but, easy of cultivation as they are, they do deserve, and fully repay, certain considerations, chief of which are:

(1) A sunny spot.
(2) Shelter from cold winds.
(3) A well drained soil.

It is important that no organic manure is used when planting; if a stimulant is wanted, bone-meal is the most effective, and quite easy to obtain. In planting, the rhizomes should be placed just underneath the soil. The flowering period of irises is from May to June, a time when their radiant effect is most appreciated. It is during the two months following flowering that the flowers for next year are formed; any disturbance during this period may have a detrimental effect on their flowering the following year. The best time for moving them is September, but planting may be carried out at any time up to the end of March with satisfactory results, although the earlier in the autumn it is carried out the better.

It is a difficult matter to describe irises sufficiently, many of the tints, reticulations and veinings being too elusive to coincide with any colours as colours are recognised; but to enable those unfamiliar with the actual flowers to design for harmony, the following list will be found most useful:

A PLEASANT ASSOCIATION OF IRISES AND LUPINS. AN ARRANGEMENT THAT SHOULD BE PRESENT IN EVERY GARDEN.

LAVENDER SHADES.

Alcazar, lavender and deep blue.
Lord of June, lavender blue and violet.
Prospero, lavender, violet purple.
Asia, silvery lavender and reddish purple.

VIOLET SHADES.

Ambassador, violet and velvety red.
Ballerine, violet blue.
Grevin, violet, shaded yellow.
Magnifica, violet blue and reddish brown.
Monsignor, violet and crimson purple.
H.M.S. Pinafore, violet blue.

VARIATIONS OF YELLOW.

Delila, yellow and plum red.
Flaming Sword, clear yellow and mahogany red.
Fro, golden bronzy crimson.
Gagus, soft yellow and crimson.

PURPLE AND LILAC SHADES.

Cluny, lilac blue.
Edward Michell, light purple.
Isolene, lilac and mauve.
Miriam, lilac.
Souvenir de Mme. Gaudichau, purple bicolor.

BLUE SHADES.

Goldcrest, light blue.
Neptune, blue shades.
Oriflamme, bright blue and purple.
Perfection, light blue and velvety black.

COMBINATIONS OF WHITE.

Jeanne d'Arc, white shaded blue.
Ma Mie, white bordered blue.
Rhein Nixe, white and mauve.

VARIOUS TINTS.

Her Majesty, rose.
Lohengrin, rosy mauve.
Prosper Laugier, cinnamon, and black satiny crimson.

All the above are in the front rank of irises and are worth a place in every garden. If space permits, it is a very good plan to have a border entirely devoted to them, for even when the flowering period has passed there remains considerable scope for the use of gladioli to prolong the attractiveness of the border.

Irises, lupins and poppies, when grouped, make a charming summer border, which remains effective for many weeks. E. M.

FORMAL BEDS OF IRISES ALWAYS LOOK ATTRACTIVE.

The crazy path and the edging of violas (Fred Williams and Maggie Mott) make for an effective display. The iris on the right is Alcazar, of a deep blue and lavender shade.

Digitized by Google

ALPINE GARDENING UNDER GLASS

The erection of an alpine house is generally the outcome of the possession of a rock garden, and no words can describe the joy of at last, with overhead protection, meeting with success in growing many of the more difficult plants which, for years, have defied all efforts and encouragement out of doors. A start should be made now so that an early spring display is assured next year.

TO rush into the building of a house without much thought and care is but a waste of both time and money, for two-thirds of the success or failure of the future lie in the making of it. Light and air, sunshine and ventilation, without drips or draughts, are the main points to keep in mind, and the essential principle on which to work is to create a home for the plants as near to their natural conditions as can possibly be contrived. For that reason, all ideas of artificial warmth should be looked upon as poison, as destructive to the plants as the overhead moisture which spells disaster to so many of our greatest treasures.

No rule, of course, can be laid down about the dimensions of the house, for this entirely depends upon what space can be given and how much time and money are to be spent both on erection and upkeep. Neither can hard and fast rules be dictated about design, for often an ideal corner can be found by using some existing wall for a background and building a lean-to house against it. In other cases a good open space will be available, where a span-roof house will be possible. Whatever design is fixed upon, the really important thing to consider is the aspect, and a spot should be chosen, at all costs, where the maximum amount of sun is obtainable.

The house should be made so that the top, front and side lights can all open, and, under the staging, sliding shutters should be arranged, to allow of a further supply of ventilation. It is a good thing to cover the openings of these lower ventilation spaces with small-mesh wire netting, so that mice—those most tiresome enemies of all small bulbs—can be kept at bay. If it is not possible to have a cement floor, the ground on which the house is to stand must be dug out for a considerable depth and filled with good sound drainage material, and the ground level covered with the same small-mesh netting, over which should be spread a thick layer of cinders. One most important point in designing the house is to see that the glass roof is not too far from the staging, for, if this be so, the plants are very apt to draw up and, in so doing, to lose their characteristic growth.

Unless it is possible to have a potting shed absolutely adjoining, it is a great asset to fix up a bench, either to fold against the wall if there is one, or to fix between the stagings if it be a span-roof house. This latter can be adjusted when required, and will in no wise interfere with the passage-way when it is not in use.

Under the staging can be fixed shelves—for pots, water-can, and all the necessary paraphernalia that attend the upkeep of the plants, and also a couple of bins with soils ready mixed, and receptacles full of limestone chips, sand, granite chips, mortar rubble, etc. Care must be taken, however, that nothing stands so as to prevent the free circulation of air from the ventilation spaces. It is quite surprising how much can be crowded into a small space if real thought and care be expended over the planning of it.

If there should be any floor space left over, it can always be utilised for seed-pans, but it would be better still to use it for a water-butt—fed from the outside gutters—which will hold a constant supply of soft water at the correct temperature, so much better for the plants than the application of hard, cold water from the tap. As the house is more likely to be on the small, rather than on the large side, it is well always to keep in mind the comfort both of the visitor and of the worker, and for this reason everything that is likely to get in the way unnecessarily should be avoided. Pots should be packed well away so that the passer-by cannot whisk them off the shelf, and the stays of the top lights must be so arranged that they cannot hit the head of anybody who is walking underneath them. By looking ahead in these matters, a day's work in the alpine house will become a pleasure instead of a task.

Having erected the alpine house, and covered the staging (which, by the way, is best made of sheets of corrugated iron) with a thick layer of limestone chips of medium size, all is ready for the reception of the plants. For a start, this may be a moment of temporary difficulty, for, unless it is possible to order recklessly the things after which the soul hankers, without regard to expense, the shelves are apt to look very large and vacant and the stuff available very small and inadequate. But the wise man will have looked ahead, and during the previous seasons he will have taken cuttings, made divisions and raised seedlings from his own and his neighbours' gardens, which will go far enough to make a fair show for a beginning.

For the first season, perhaps, it will be permissible to include a few plants, which, later on, when space gets more and more valuable, will be ejected to take their proper place in the rock garden outside. Such things as aubrietias and mossy saxifrages will make a brave show when there is too much room available, but they will have to go when, after the first winter, more and more of the rarer plants are clamouring for admittance to the house. In fact, it is constantly necessary to harden the heart, and to continue a stern process of elimination as far as qualification for admittance is concerned.

In selecting the plants to be grown, the chief thing to remember is the time of flowering, for only the real winter bloomers will be wanted. The season of the alpine house lies roughly between November and April, and by the time May arrives there will be so much in bloom out of doors that there will not be much sense or satisfaction in producing a gay show within. Added to which, the heat, after the end of April, will generally be quite enough to destroy entirely all the characteristics of the alpines grown under glass. When that time comes all the occupants of the house should be turned out into their summer quarters—that is to say, into open frames, where the pots can be plunged up to their rims in sand, cinders or fine gravel—there to remain until they are required the following season.

About the first plants to bloom in the house will be the early bulbs, and, in order to get them as soon as possible, they should be potted up not later than August and brought on with as little delay as may be. By the time that there is no further danger of the house being too hot, as many of the plants, which have been summering outside, as there is room for can be brought in, leaving a supply in the frames which can be drawn upon to fill up gaps as the season advances. From the moment that the first of the autumn cyclamen appears, there will not be a dull moment in the house, and every week, and sometimes every day, will bring a fresh thrill as the plants come into bloom in quick succession. There is an infinite satisfaction in seeing plants growing in perfect happiness and comfort, untouched by rain and storm, and yet uncoddled and under perfectly natural conditions. Such things, to name but a very few, as crocuses; the miniature members of the narcissus and of the tulip families; soldanellas; saxifrages in their infinite variety; fritillarias; small iris; primulas. These alone make a few square yards of glass a possession of unending interest and satisfaction.

On bad days, when rain and storm make work outside an impossibility, there is always a day's work to be done in the house—weeding, top-dressing, labelling, together

THE BEAUTY OF AN ALPINE HOUSE IN EARLY SPRING.

TWO GOOD PLANTS FOR A BEGINNER'S ALPINE HOUSE COLLECTION.

The dainty and free-flowering Primula rosea. *One of the best of rock foils for the amateur, Saxifraga apiculata.*

with the many other little attentions which add to the comfort and the well being of the plant.

When the season draws to an end and the plants have been turned out into their summer quarters, the house should have a thorough clean, and this, of course, should be repeated at the end of the summer, before the plants are brought in again. During the summer the house need never be empty, and it can be used for many purposes—from growing tomatoes to drying-off bulbs and seed-raising.

Outside, once the pots are plunged in the frames, there will not be much to do. All that is necessary is to keep them well watered and free from weeds, and an occasional top-dressing will seldom come amiss. Of course, care should be taken to have frames of the proper aspect, giving a cool position to the shade-lovers and a warm spot to those which delight in full sun.

The following plants are all suitable for growing in the alpine house, but this list is nothing like complete :

Androsace.—Chumbyi, chamæjasme, villosa.

Crocus (*both spring and autumn*).—Biflorus, Imperati, Olivieri, speciosus, sativus, Sieberi, Salzmanni, Susianus, Zonatus.

Cyclamen (*both spring and autumn*).—Coum, cilicicum, ibericum, europæum, neapolitanum.

Campanula.—Chrysantha, Steveni.

Dianthus.—Microlepis, macrocarpa rumellius.

Draba.—Pyrenaica, cuspidata, Sundermanni.

Eranthis.—Cilicica.

Erythronium.—Californicum, revolutum.

Erica.—Carnea.

Fritillaria.—Amœna, pyrenaica.

Galanthus.—Cilicicus.

Gentiana.—Acaulis, verna.

Iris.—Alata, cristata, histrioides, lacustris, reticulata, persica.

Lithospermum.—Heavenly Blue.

Muscari.—Azureum, Heavenly Blue.

Morisia.—Hypogæa.

Narcissus.—Bulbocodium, corbularia, cyclamineus, minimus, triandrus albus.

Primula.—Allionii, auricula, farinosa, frondosa, helvetica alba, involucrata, marginata, pubescens alba, rosea, Winteri.

Raoulia.—Australis.

Soldanella.—Alpina, montana, pusill.

Sisyrinchium.—Grandiflorum.

Sedum.—Pulchellum, arachnoideum, spathulifolium, kamtschaticum.

Silene.—Acaulis.

Saxifraga.—Apiculata, Burseriana, baldensis, cochlearis minor, cartaliginea, Elizabethæ, Haagii, Irvingii, longifolia, lilacina, oppositifolia, Paulinæ.

Tulipa.—Biflora, Clusiana, Kaufmanniana.

RENOVATING THE HERBACEOUS BORDER

The Importance of Labelling at the Present Time.

DURING the summer months observations regarding the reconstruction of herbaceous borders which have become much overgrown should have been made, and the basis of reconstruction will commence during September and October in the systematic labelling of all plants. Very often this important point is disregarded, and when the time comes to replant the border there is much confusion and, consequently, mistakes are the result. Even experienced gardeners have had to suffer the eyesore for a season of two different coloured plants which neither blend nor tone, being planted side by side, or of a dwarf plant being planted at the back instead of the front of the border. It is not often easy to recognise plants by their roots, so that labelling before the foliage dies down greatly assists the amateur. Not only the name of the plant should be written on the label, but the height of each plant and its colour also. This greatly helps the amateur when the time comes for remodelling the border.

To maintain a perfect border the remodelling should take place about every three years no matter how large or how small the border is. The anxious amateur who longs to see a well filled border, and who accepts every gift of cutting or plant from his neighbour and friend, soon finds his border overcrowded with the only possible solution of remedy—reconstruction.

The inexperienced gardener simply regards this task lightly, indiscriminately lifting every plant out of the border, trenching it and replanting; but he soon finds to his cost the following year that the fruit of his labours are not to be compared with those of his experienced neighbour.

Such plants as the delphinium, kniphofia, peony, Madonna lily and the iris object to being ruthlessly torn up, so that in the trenching of the border these plants ought to be left to remain and the trenching done around them, and the colour scheme being worked around them accordingly when planting.

Other herbaceous plants should be carefully lifted and "heeled in" in some corner of the garden until the soil has settled down again after trenching, when they can be replanted. All strong-growing plants such as Michaelmas daisies, heleniums and phloxes should be divided before they are replanted in the border.

Trenching is done about November or as soon after the plants have died down. The soil should be dug to the depth of 2½ft. to 3ft., and old decayed manure worked in between the lower spits, *i.e.*, the lower layers of soil. This improves the border and induces the plants to seek their nourishment lower down, which in dry seasons assists the plants in obtaining their supply of moisture. To make sure the border is level allow it to remain until it has had a good shower of rain.

In case there are some who desire a little guidance in the purchasing of new stock, the following are a list of suitable hardy border plants :

Early-flowering Hardy Plants.—Doronicums, peonies, pyrethrums, irises (some), coreopsis, Canterbury bells, aquilegias, geums and pinks.

Mid-season Hardy Plants.—Campanulas (most), delphiniums, eremuri, foxgloves, hollyhocks, verbascums, monksbood, galtonias, lilies, lupins, lythrums, irises (some), moon and ox-eye daisies, phloxes, rudbeckias, anchusas, spiræas, anthericums, carnations, evening primroses, gaillardias, day lilies, incarvilleas, lychnises, poppies and achilleas.

Late-blooming Hardy Plants.—Sunflowers, golden rods, Michaelmas daisies, heleniums, Japanese anemones, pentstemons, kniphofias and Sedum spectabile.

With these and many other kinds of plants and bulbs a discreetly planted border will add grace and beauty to the border and unlimited interest to the owner. M.H.G.

A BORDER OF BULBOUS PLANTS

Why not have a border next year devoted entirely to bulbous plants? If care is given to the selection of subjects the border may be made to provide colour and flowers over a long period.

A BORDER planted exclusively with choice and interesting bulbous plants may become a most pleasing addition to the amenities of the garden, and it is surprising what an extensive collection of plants may be grown in a comparatively small space. The majority of bulbs require all the sunshine possible, and many of them must be subjected to a thorough ripening in order to induce satisfactory floriferousness, so that an ideal position for the establishment of a collection of bulbous plants is a border situated at the base of a south wall, and even better still is one under the southern wall of a glass structure, for in the latter position the bulbs will probably derive a little benefit from the heated greenhouse.

The soil must be of a lasting nature and should consist of good mellow loam three parts, good leaf-soil and plenty of sharp sand, and an appreciable depth of this material, 18ins. to 2ft., should be provided. If the ground is not naturally well drained, it will be advisable to remove the existing soil to a depth of 2ft. and place in the bottom of the border a layer of broken bricks or stones, the former for preference. Over this drainage place a good layer of rough turf or lumpy loam and then fill in with the compost before advised, rendering the whole firm but not unduly hard. The border may be edged with informal stones, and it is an excellent plan to use a few suitable stones on the border itself, as some of the smaller plants undoubtedly enjoy the proximity of a cool stone, and the combination is often particularly charming. Do not, however, overdo the use of stone, but rather use a few carefully selected pieces casually and artistically for the sole purpose of creating a happy environment for certain plants.

From the end of August to the middle of September forms the ideal planting season for the majority of bulbous plants, but there are certain subjects which cannot be planted until spring. The nucleus of a good collection may be formed, and later it is a great happiness to collect and plant such treasures and rarities as the depth of one's pocket and the generosity of one's friends may permit. It is difficult to name another class of plants, hardy plants at any rate, that is capable of giving so much pleasure or creating so much interest as bulbous plants, and it is possible to have something in flower almost every day in the year with the possible exception of mid-winter. Very early in the year the snowdrops will gladden with their drooping white pearls, and a good selection should include, in addition to the ordinary Galanthus nivalis, G. Elwesii, G. plicatus, G. Imperati and G. Fosteri; and contemporaries of these fine snowdrops are the winter aconites, the common Eranthis hyemalis, the little-known E. cilicica and that fine hybrid from E. Tubergeni. Not on any account must the early-flowering Cyclamen Coum be forgotten, and the enthusiast will soon get together a representative collection of early bulbous irises, such as reticulata, persica, the quaint tuberosa, Danfordiæ, Histrio, histrioides and bucharica. Such early crocus as Imperati, Korolkowi, susianus, Tomasinianus, Sieberi and chrysanthus are indispensable, and during the autumn we may again have crocus as represented by C. speciosus, C. pulchellus and C. zonatus, accompanied by the late summer and autumn cyclamen, C. neapolitanum and C. europæum. Colchicums, as C. speciosum, the incomparable C. s. album, C. Bornmulleri and our own native C. autumnale should be in every garden. The crocus-like Bulbocodium vernum, the romuleas, Cypilia Herbertii, the glorious Amaryllis Belladonna, Nerine Bowdenii, choice montbretias, crinums, the pretty little Anamotheca cruenta, such tulip species as Greigi, Eichleri, Fosteriana, clusiana, persica, dasystemon, pulchellus and linifolia, many of the muscari, chionodoxas, scillas, erythroniums and quaintly beautiful fritillarias as FF. latifolia, recurva, pudica, coccinea, Thunbergii, acmopetala and pallidiflora may easily succeed admirably in a well placed and well tended bulb border.

A DECORATIVE SPRING BORDER OF BULBS.

A bright display may be obtained by planting daffodils, scillas, crocuses and snowdrops in bold clumps, such as has been done in this instance.

The list of bulbous treasures is almost inexhaustible, from the dainty little Narcissi Bulbocodium, triandrus, juncifolius and cyclamineus to such gorgeous plants as the calochortus, tigridias, ixias, sparaxis, brodiæas and babianas, these latter somewhat tender plants best succeeding with a little protection. Some few of the smaller lilies may be introduced into the border, the larger species if the available space is sufficiently large, and alstroemerias, not strictly bulbous, always harmonise happily with the plants here treated.

I have accorded but scant justice to bulbous plants, and even as I draw these notes to a close I am assailed with alluring thoughts of such beautiful subjects as sternbergias, zephyranthes, Habranthus pratensis, Schizostylis coccinea and Dierama pulcherrimum.

A collection could be started with crocuses, both autumn and spring flowering, scillas, chionodoxas, narcissi and snowdrops. More uncommon bulbous plants could be added to this collection as time goes on. R. E. A.

CRINUMS WITH THEIR HANDSOME FOLIAGE AND ATTRACTIVE CLUSTERS OF FLOWERS ARE WELL SUITED FOR FILLING A SHELTERED AND SUNNY BORDER.

THE BUSY MAN'S PAGE

September Reminders.

EARLY apples and pears should be gathered. Keep all runners cut from strawberry plants.

Remove mulching from any fruit trees, as it will be an advantage to allow the ground to become sun-baked when all that remains to be accomplished is the ripening of the crops.

Earth up celery and, if possible, plant a few rows for late cropping.

Plant cabbage, lettuce and endive and make a final sowing of the two last-named.

Sow prickly spinach for late crop early in the month.

Some parsley plants may, with advantage, be removed to a sheltered position, where they will continue growing during the winter.

Main-crop potatoes will mostly be ready for lifting, and the ground can then be filled up with cabbages, Brussels sprouts, kale, savoys, onions, etc., that have not yet been taken from the seed-beds.

The haulms of potatoes and also any club-rooted stems of cabbage, turnip, etc., should be collected and burned. If these are allowed to lie on the ground and rot there will be great risk of spreading disease.

After the middle of the month there is not much chance that outdoor tomatoes will ripen in the open. The sizable fruits should be picked and laid out in layers in a warm and dark place. If exposed to direct sunshine the tomatoes will almost certainly shrivel.

By the end of the month the bedding plants will be looking in poor condition. Those required for stock should be cut back and potted or put in boxes and placed in the greenhouse or in a frame for protection.

The beds and borders where the plants grew should be well dug and prepared for the planting of bulbs.

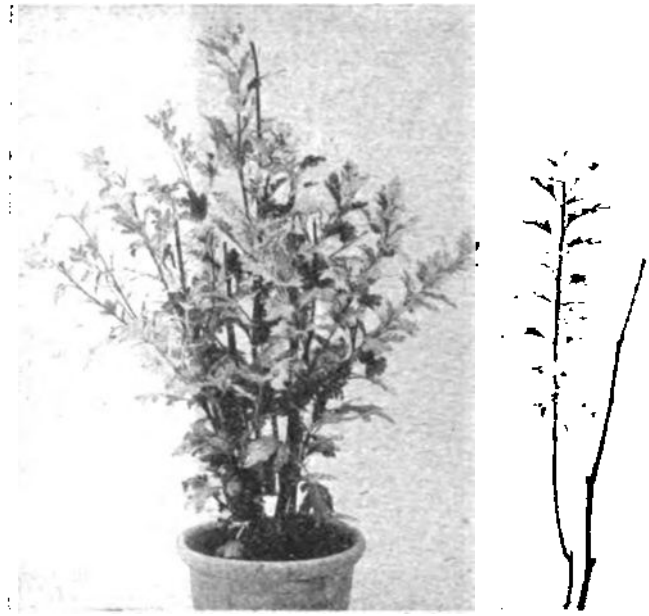
Arum lilies may now be potted up for flowering in winter and early spring.

The corms of gladioli may be lifted when the leaves have withered and, after cleaning, may be stored in dry soil or sand during the winter months.

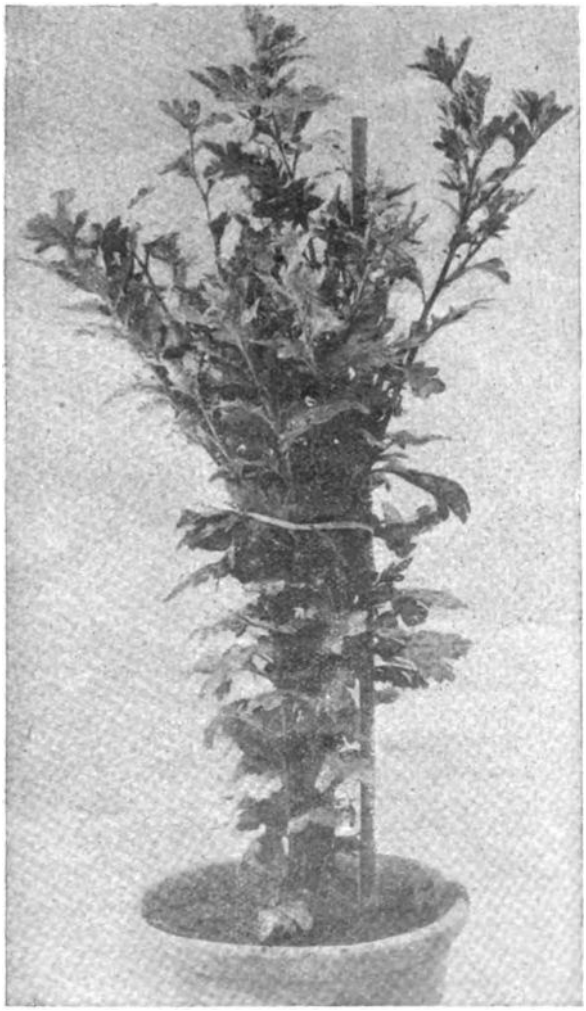
Except in the south of England, it will be time to lift dahlia tubers towards the end of the month, and the same must be done in the case of the tubers of begonias and the rhizomes of cannas.

Cuttings of shrubby calceolarias, penstemons, antirrhinums, phloxes, etc., may be inserted in cold frames at the end of the month.

In all parts of the garden continue the attack on weeds which will often grow with great vigour at this time of the year.



2.—THE CORRECT WAY OF STAKING AND TYING.
Each shoot has sufficient space in which to develop.



1.—A COMMON MISTAKE WHEN STAKING AND TYING CHRYSANTHEMUMS.
All the stems are tied in a dense bunch.

Staking and Tying up Chrysanthemums.

THE staking and tying up of chrysanthemums should be done, as and when required, from the time the plants give evidence of needing support to maintain their growths in an upright position. The object of staking and tying these plants is to afford support to the shoots just when they need this help. A keen observer will be quick to note that, as soon as a plant has reached a certain period of its history, having previously grown along freely and satisfactorily, it appears to stand still for a time until the growths are afforded the support they need, subsequent to which period they invariably go ahead again. For this reason chrysanthemum plants are staked and tied, *i.e.*, the shoots are lightly yet securely looped to the stakes that are inserted here and there among the growths. Neglect in this work is a great misfortune, for, apart from the disadvantages that follow delay in this matter, the plants get out of shape and lose that pleasing contour for which carefully grown chrysanthemums are quite famous. To meet the probable requirements of the beginner, in Fig. 1 is shown just an ordinary small bush plant that is commonly found in most gardens where chrysanthemums are grown for cut flowers or for conservatory embellishment. This illustration shows a plant that has been tied up wrongly. Bunched up as the shoots are when so treated, it is next to impossible to achieve results that are in the least degree pleasing, and it is a practice that should be most rigidly eschewed if the grower desires success to attend his efforts.

In Fig. 2 the same plant, properly staked and tied, is shown. Here it will be noticed that about half a dozen small stakes have been inserted, and in such a way as not to be very aggressive. Another fact that needs attention is that the stakes are disposed at such an angle as to keep the shoots well apart from one another, so that air may pass through them quite freely and that the sun may make its influence felt throughout the whole of the plant. It would be possible with such small bush plants to insert a bamboo cane or stout stake in the centre of the plant and to loop each of the shoots to this. To carry out this method of staking and tying satisfactorily, it would be necessary, first of all, to make a tie with raffia round the stake, and then to bring within another loop-like tie the growth it is desired to control. This must be done so that the loop allows sufficient play for the shoots in windy weather. This method of tying should be adopted in the case of all chrysanthemums, and is clearly portrayed on the right of Fig. 2. (Note the stake to which the raffia is tied, and then the loop-like tie that controls the shoot of the chrysanthemum). Before inserting the stakes in the soil of the pots or in the open border, see that they are sharpened to a point. They should then be inserted 1in. or 2ins. away from the base of the main stem of the plant.

Earthing Celery in Three Stages.

THE process of earthing up celery plants is best done in three stages. Collect the leaf stalks together, and about 8ins. from the base tie round a piece of raffia or string; leave the tops loose at first, allowing the growth to continue. At intervals of two or three weeks, repeat the operation, finishing the earthing up at the approach of frosts. It is best to earth celery when the soil is not too dry or too wet. If a dusting of lime and soot is given along the rows before earthing, insect pests will be kept away.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Taking Cuttings this Month.

ONE is usually advised to take cuttings of the majority of plants during September, but I think that the last week in August and the first in September are ideal for increasing plants, especially soft-wooded plants such as geraniums, salvias, etc. A wet season is favourable to the plant propagator. In showery weather there is no difficulty in rooting many of the common plants outdoors in the open border. It is a little early to make cuttings of hard-wooded plants, like roses and shrubs, as the wood in many cases has not finished its growth, and has not reached that degree of *ripeness* which will ensure the successful taking of cuttings. Where the wood has obviously finished its growth, even these could be inserted in sandy soil outdoors, with every prospect of success.

The following table of soft-wooded cuttings that may be taken now will be useful to owners of small gardens:

Name.	*Length of cutting.*	*Distance apart to insert*
Geranium (zonal pelargonium)	4ins.	4ins.
Salvia patens and S. splendens	3ins.	3ins.
Calceolarias	3ins.	2ins.
Violas and pansies	3ins.	2ins.
Pinks	3ins.	2ins.
Carnations	3ins.	3ins.
Pentstemons	4ins.	2½ins.
Arabis	3ins.	3ins.
Aubrietia	2ins.	2ins.

Of these, geraniums, salvias, calceolarias and pentstemons are best struck in boxes, to be lifted into the cold frame when frosts arrive.

Owing to the sappy nature of growth this year, it would be advisable not to mix any leaf-soil at all when preparing the compost for boxes. Use a mixture of 2 parts fibrous loam and 1 part sharp sand, with a layer of rough leaves at the bottom of the box for drainage. Where only a few cuttings are required, pots could be used instead of boxes.

Hillside Gardens.

THE garden which runs uphill from the house presents a difficult problem to the garden planner. In the accompanying picture, the portion of the garden nearest the house has been excavated, and levelled for about 6yds., using the bank thus formed as a site for a rock garden. The steps lead to the higher level, in which a rose garden has been made. Thus, as it were, there are three gardens in one. A formal garden near the house, with lawn and flower beds, then a rock garden, and through this steps lead to the rose garden on a higher elevation. This is made picturesque by the use of pillars of climbing roses.

A PATH OVERGROWN BY "SNOW IN SUMMER."
Plants should be cut back at this season.

An Overgrown Walk.

CERASTIUM—the grey-leaved "Snow in Summer"—makes a charming edge to the garden path, but it tends to encroach too far on to the footwalk. It can be safely trimmed back at this season, and it will make an abundance of fresh growths from the base in readiness for next season's flowers. The variety shown in the picture is Cerastium Biebersteini, and there is another closely allied species, tomentosum. Both are alike in having pure white flowers, which are borne in profusion in summer, and silver leaves which make ideal edges through the winter. They do not require a rich soil, and I have seen them flourish on a dry stone wall, on a roof garden, and in other positions where moisture is lacking. They can be increased by cuttings taken at this season, or from seeds.

A WELL PLACED SCREEN OF ROSES WILL MAKE A SMALL GARDEN SEEM LARGER.
Note the use of trailing plants over the low boulders and the steps.

Bulbs in Pots and Bowls.

Hints to Ensure Success.

WERE your bulbs a failure last year, or did they not quite come up to expectations? If so, I am going to suggest a method of culture that will ensure complete success. Of course, I am assuming that you will get the best quality of bulbs. Remember that size is not so important as weight, and a relatively small bulb of a hyacinth or daffodil, provided it is solid and *heavy*, will give a fine display of blossom. The whole secret of success with bulbs in pots or bowls lies in keeping them dark, moist but not too wet, and cool. To ensure this, the best method I know is to bury the pots and bowls of bulbs under a layer of finely sifted, moist coal ashes. Where accommodation is limited, an egg-box would be suitable, in which to make a plunging bed of moist ashes. The box could stand out of doors, and be protected from excessive rains by means of a cover. But this is important: *air must have access* to the bed of ashes under which the bowls are plunged. After about six weeks, inspect a few of the bulbs to see how the growth is progressing. They need not be moved from the ashes until an inch and a half of top growth has formed. Then they may be moved to the light gradually.

This plunging method saves a certain amount of labour in watering, as, after the initial watering when the potting is done, no further watering will be required until the pots are removed from the ashes.

Hyacinths in Water.

I WAS in a semi-basement office last spring, where I saw a pleasing display of bulbs, chiefly hyacinths, grown in water. This method of culture is exceedingly fascinating. It affords continuous interest from the time the bulbs are set into position in the special glasses now sold everywhere for this purpose, until the flower spike finally unfolds its treasures.

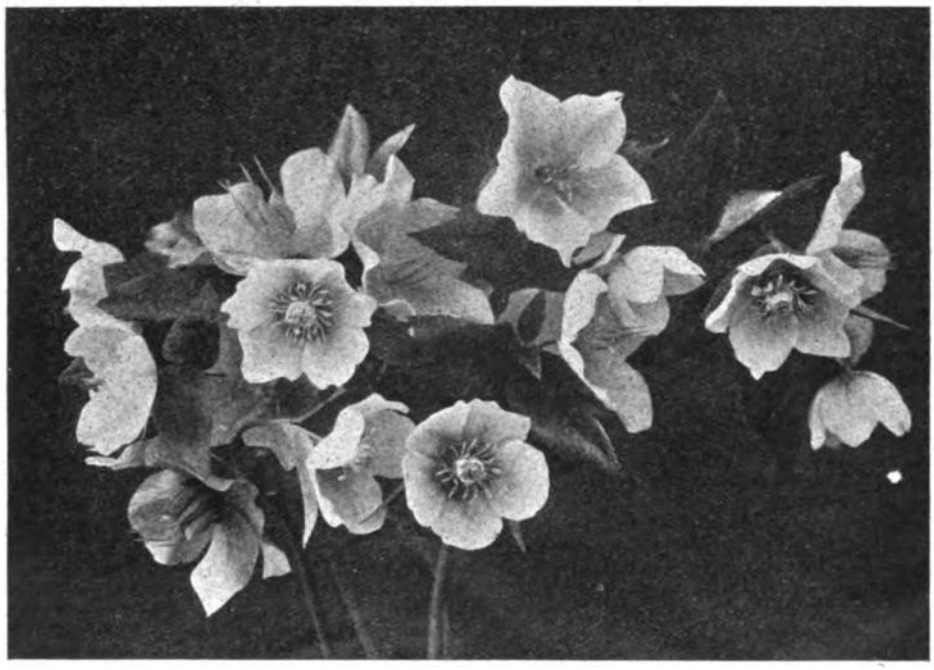
NOTES ON THE FLOWER GARDEN

Some Attractive Christmas Roses.

BESIDES our common Christmas rose, Helleborus niger, H. orientalis with its numerous varieties is a most beautiful one. Among the white-flowered varieties of orientalis the form H. olympicus is a plant of great merit for the wild garden. This spring I saw a large group of it in the famous shady drive of the Botanical Garden at Nymphenburg, near Munich, Bavaria, standing in full flower for weeks. It forms large bushes with its well known evergreen foliage and leaf-like bracts on the forked flower-stems that bear from two to six comparatively small but lovely flowers of a snowy white on the outer side of the sepals, well represented in the accompanying illustration.

H. olympicus is one of the parents of the countless forms of hybrid origin so highly praised in our gardens. A very similar species or variety is H. antiquorum, of which



HELLEBORUS ORIENTALIS, A BEAUTIFUL CHRISTMAS ROSE FOR THE WILD GARDEN.

the flowers are somewhat arger and more bell-shaped, of a pearl-pale white with a pinkish hue. The true H. caucasicus represents a green-flowered variety of H. orientalis. The sepals are suffused with purple. H. caucasicus is dwarfer than its congeners and has single very glossy leaves. Among the deeply purple-flowered sub-species of H. orientalis, H. colchicus is the best known and the finest one. Its stems, too, are spotted with purple and bear a glaucous hue.

A very interesting form is found in Hungary, called H. atrorubens. It has thinner glabrous leaves with narrower segments, and it is regarded by some botanists as a connecting link between H. orientalis and the well known European species H. viridis. Its flowers are of a deep claret outside and rather greenish purple within. I have never met with another variety called H. torquatus, which, according to Reginald Farrer, is the strangest and rarest of all, with noble flowers of a bloomy powdered-looking steely slate blue.—C. S.

A Fine Plant for the Border.

(The scarlet bergamot).

IN the scarlet bergamot (Monarda didyma), we have a robust and strong-growing plant, very suitable for creating a bold splash of colour in the herbaceous border, or in beds during late July and the following two months. Moreover, it is adapted for the semi-wild garden where the surrounding growth is not too rank, and if the soil is on the damp side so much the better. In the ordinary border it is not too rampant, and it will make a clump 1½ft. to 2ft. high and prove most effective throughout the summer. The bright red flowers are produced in whorls, being supported by a leafy bract, while the leaflets are pale green tinted with red. The variety Cambridge Scarlet is much brighter than the type, and this should be chosen in preference to all other forms or named varieties. It is, indeed, a glorious plant, and will succeed in any soil. The growths are stout and strong, and the plants do not require any staking, a fact worth noting. Propagation is effected by division during the autumn or winter months, and a group of several examples is better than a few isolated specimens.—B. T.

A Decorative Shrub for the Border or Rockery.

(Abelia Schumannii).

THE abelias are charming shrubs that flower for the most part towards the end of the summer, and in Abelia Schumannii we have a decided acquisition to the genus. It is a native of China, and received an award of merit from the Royal Horticultural Society on July 13th, 1926. The leaves are ovate and opposite, and the rosy lilac flowers are freely produced from early July till the autumn. The leaves are often tinted with bronze, and the blooms appear at the ends of arching shoots, the side growths also giving their quota of flowers, which renders the plant extremely floriferous.

The whole plant is distinct and forms a spreading shrub, rather pendulous in habit, and for this reason it should be an ideal subject for clothing a large boulder on the rock garden, or covering an isolated stone near by. In all probability it will prove hardy in most districts, but as yet it is too early to make any definite statement. It strikes easily from cuttings, so it should soon be available for every garden; moreover, it begins to flower when only a few inches high.—W.

A Useful Late Summer and Autumn Flowering Shrub.

(Eupatorium Weinmannianum).

THIS is a plant that deserves to be more largely grown, but in all probability many consider it a tender subject, and on that account pass it by. It is not, however, sufficiently hardy for every district, nevertheless, there are many places where it would thrive outside. Around Penzance I have seen some good specimens, and here at Castleford, Chepstow, it forms a fine bush in the shrubbery and near the rock garden, while, I believe, fine examples are to be found in the gardens of Sir Herbert Maxwell. For south-west counties it could safely be grown as a bush, and it would attain a height of 4ft. to 8ft.; in less favoured areas it could be utilised as a wall plant with a south or south-west aspect. It is very free-flowering, and the plant is nearly covered with clusters of white fragrant flowers, which are succeeded by fluffy seed vessels, these being most attractive for several weeks.

As an elegant greenhouse plant it has much to commend it, and for the cool house it can be relied upon to furnish a good display during the month of August. When grown in pots a rich soil is needed, and directly the receptacles are filled with roots, liquid manure or some reliable fertiliser should be given once or twice each week.

The partially ripened shoots make excellent cuttings, and they will readily form roots during August or September in a cold frame or in the spring if afforded a little heat.

This desirable eupatorium is quite distinct, and, moreover, it flowers at a period when flowering shrubs are rather scarce.—T. W. B.

A Good Ground Cover for Sun or Shade.

(The Japanese spurge).

A SPLENDID evergreen ground cover of especial value for planting beneath trees, in shady corners, on difficult banks and in similar situations so well known to every gardener and so difficult to furnish suitably, is the Japanese spurge (Pachysandra terminalis). This is quite a distinct plant from the true spurges (euphorbias), although the plants are related botanically.

My attention was first drawn to the obvious merits of Pachysandra terminalis for this purpose, in New York, where it is planted very extensively in the majority of gardens. The winters there are much more severe than in Britain, while the summers are exceedingly hot, yet the Japanese spurge comes smiling through these extremes of temperature and appears to thrive amazingly.

It has much the habit of Hypericum calycinum (St. John's wort) being semi-woody and evergreen in character, and growing to about 8ins. in height. The foliage is very attractive and the leaves are borne in a cluster-like arrangement at the end of the growths, remaining in good condition two or three seasons. The purplish-green flowers are borne in short terminal spikes in the spring.

Prior to planting the ground should be well prepared and enriched by the addition of some leaf-mould. From 9ins. to 1ft. apart is a good planting distance, and the autumn is the best season for carrying out the operations. Once established, no further attention is necessary for years, as it is one of those all too

Digitized by Google

rare plants that are capable of taking care of themselves. Cuttings inserted during the summer months afford a ready means of propagation.—GREYSTONE.

Bulbs for the Rock Garden.

FOR brightening up the rock garden in the early months of the year one cannot equal some of the bulbous plants. Many of the bulbs will flower at an earlier date than usual on a rockery, especially if they can be given snug, sunny corners. After flowering, the bulbs can often be left where they have bloomed to come up again next season, and in no way will they interfere with the other occupants of the rock garden. In practically all cases planting in masses is to be strongly advised. A good rule is to have each bulb separated from its fellows by the distance of about two diameter measurements across the bulb. When making up the bulb order some, at any rate, of the undermentioned should be included for planting on the rock garden.

Several anemones are highly suitable, but none of the following should be omitted: blanda, hepatica, apennina, fulgens and St. Bavo. Anomatheca cruenta is a pretty little South African plant with carmine flowers. It is hardy in warm positions in most parts. Practically all the chionodoxas and crocuses are excellent subjects for the rock garden. A place should also be found for some of the dog's tooth violets (erythronium), especially grandiflorum robustum, yellow; Hendersoni, lilac shaded with maroon, with yellow centres; White Beauty, large creamy white with maroon base; Johnstoni, rosy pink. Both the feather and grape hyacinths are strongly to be recommended for positions on the rock garden. Several of the early-flowering iris are valuable subjects for the purpose under consideration, but special mention may be made of II. tuberosa and reticulata. The dwarfer kinds of narcissi should also be considered, and of these the following are worthy of note: hoop petticoat, moschatus, nanus, Queen of Spain, triandrus albus, juncifolius, minimus, and Tom Thumb. Oxalis adenophylla has proved to be quite hardy in most places and, apart from its bright pink flowers, the plant is attractive on account of its foliage. Scillas and snowdrops may be freely used. Most of the tigridias flower in the summer, but T. violacea develops its rosy purple blooms in April and May. Triteleia uniflora, with very fine lilac blossoms, flowers at about the same time. Duc van Thol tulips, in all available shades, can be relied upon to give some fine patches of colour in the rock garden at an early date.—S. L. B.

Sowing Seeds of Antirrhinums and Pentstemons.

THE antirrhinum, especially, is a very accommodating plant, and if the variety Nelrose is included in the collection, flowers may be grown nearly the whole year round. Of the sort Nelrose, I have had splendid spikes of flowers in boxes in spring, the seeds being sown in late August or early September. When the spikes of flowers were cut, the plants were planted out in the open border, where they soon produce a little forest of flower spikes again, and continued to do so throughout the winter in the south of England. I am now advocating the sowing of the seeds with a view to flowering the resultant plants in the open borders early next summer, so we shall have to treat the plants hardily throughout the winter months.

A PLACE SHOULD BE FOUND IN THE ROCKERY FOR THE DOG'S TOOTH VIOLETS.
These may be planted this month.

I have wintered them in a cold, clayey soil, but this is not an ideal rooting medium. These plants thrive best in a naturally light, dry soil, but quite in the open quarters, and they will prove ideal, too, for flowering next summer in naturally dry borders. Sow the seeds now in boxes and duly transplant the resultant seedlings 3ins. apart in a nursery bed. To succeed with the pentstemon you should select a sheltered border or a cold frame for the resultant seedlings in the northern counties. In the southern, an open border will do nicely.—CHRISTCHURCH.

PRIMULA MOOREANA WITH ITS HANDSOME HEADS OF VIOLET PURPLE FLOWERS AND WHITE POWDERED STEMS FLOURISHING IN THE ROCK GARDEN.

An Attractive Primula.

DURING the month of August, Primula Mooreana has been making a fine display on the rock garden, and, apart from its beauty, it deserves to be largely grown on account of its late-flowering qualities. With the exception of P. Littoniana, which is quite distinct, no other member of the primula family is in bloom. For ordinary purposes it may be considered a form of the well known P. capitata, but P. Mooreana may be looked upon as the best of the group. It is certainly similar to P. capitata, but its handsome heads of violet purple flowers render it a valuable subject for the rock garden. We have it growing in a cool, partially shaded spot, and well drained, the soil being a mixture of loam, leaf-mould and sand.

Like many others of the genus, I do not think individual plants are long lived, and a friend of mine at Newport tells me he has lost most of his plants immediately after flowering. This may be due to the heavy rains during the last few weeks, but readers' experience with P. Mooreana would be helpful, especially the longevity of the plants or otherwise. It sets seeds freely, so no difficulty should be experienced in keeping up a stock. With many primulas, I believe, it is necessary to raise a batch occasionally from seeds.—CHEPSTOW.

HOW TO MAKE AND MAINTAIN A LAWN

Work to be Undertaken during the Autumn Weeks.

AFTER a strenuous season's wear and tear, every lawn should receive care and attention if it is to remain in good condition over the winter. This summer, although we hear few complaints of lawns wearing bare in droughts, many look debilitated, and all will be improved by attention. As a "refresher," nothing is better than a thin mulch, spread evenly over the lawn, not deep enough to bury the grass. Sand is most commonly used, but it is well known that porous soils produce better grass when the mulch is composed of finely sifted soil which is rich in humus, finely sifted leaf-mould, sifted fibreless manure, or a mixture of these. After application, the grass comes up wonderfully strong and, by spring, the mulch is part and parcel of the soil itself. In addition, patching may be required for lawns badly worn in places; take care that the turf used to replace a worn corner is clean and as nearly as possible uniform with the lawn. Scarifying such a bare patch, sowing seed and rolling, may serve, provided that birds, feet and other nuisances are kept away until the grass becomes established and robust; this takes a good time.

Daisies, moss and clover are pests in some lawns. First of all, clean the surface with a short-toothed rake or with a heavy harrow made of wood beams and nails; this removes a great deal, but a chemical mulch is required in addition. On a wet lawn apply ground lime (lime encourages clovers, however), but the usual dressing is sulphate of ammonia and sulphate of iron, the commercial copperas, 4 to 1, at 1½ oz. or so per square yard, or, better still a ready-made mixture bought from one of the many firms advertising in THE GARDEN. Deep-rooting weeds must be spudded out by means of an extractor first dipped in a caustic fluid, or by getting a stout kitchen fork and going down on hands and knees. Daisies and plantains can be removed with a weed grubber.

A feeding mulch of loam and manure will do good to exhausted and patchy lawns, or artificials can be used. Basic slag, 4–6 oz. per square yard, is good for fine grasses (encourages clover); kainit is required in a light soil, or potash salts (3 oz. of either) may be applied. Coarse bonemeal is first-class, although I like to apply this best in January. A sour lawn, one in which weeds begin to grow and increase, needs lime; the lime, of course, must be in fine powder form. For a bad case I recommend at least 4 oz. of ground lime per square yard; but in other cases the lime dressing may be sifted, slaked lime, or ground carbonate of chalk.

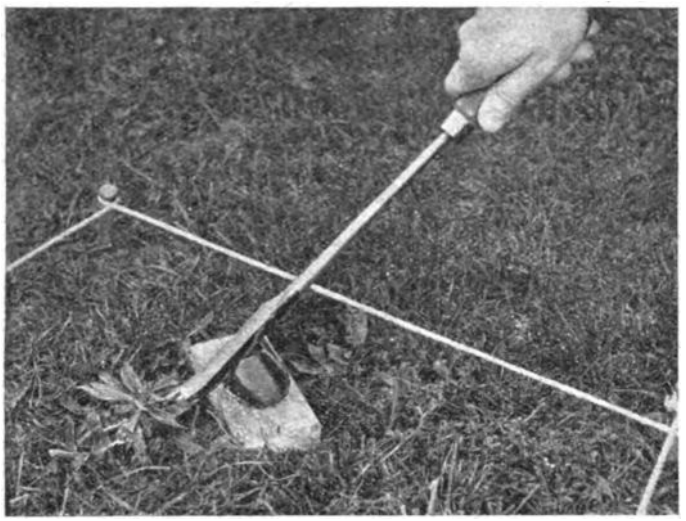
A curious souring results from over-rolling, especially when the ground is damp; this causes the surface to become hide-bound and as tough as leather, the grass being poor and the whole unsatisfactory. Holing is adopted as a cure, holes being made with a fork as closely as may be, all over the lawn; if sand is scattered after this, it enters these holes and keeps them sufficiently open to assist aeration and drainage. Mowing may cease at an early date; I always like to see the grass left to grow a little longer than usual in winter, even at the expense of neatness, because such grass seems to gain vigour thereby.

The time is at hand when new lawns may be made, and if it is decided to raise them from seed then the sooner the work is commenced the better. Except where the ground is of an open porous nature, it is essential to dig up the ground first to a fair depth. After this, however, it must be allowed to settle and become firm; a wet day or two is good for this and rolling it for that purpose should be avoided, unless dryness prevails. Needless to say, every effort must be made to secure a firm level surface in fine tilth. If turf is laid it must then be laid evenly and fine soil brushed into the seams as far as possible. Slight irregularities, as determined by means of a long board laid on edge, may be removed by beating with a wooden maul.

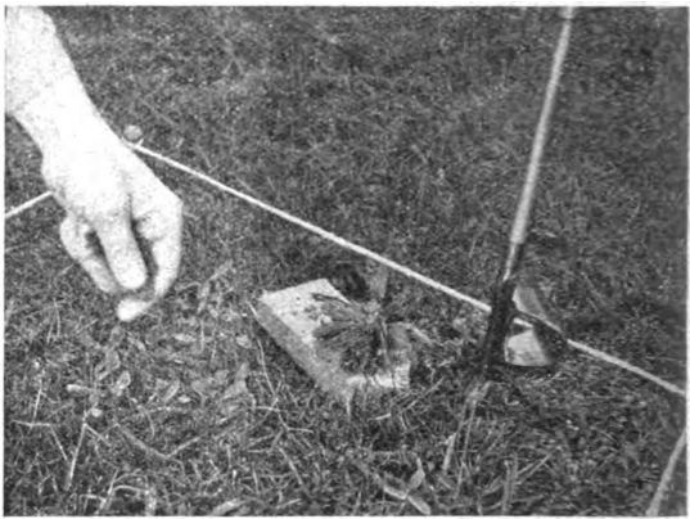
Seedsmen now supply excellent grades of lawn seed mixture, so that the gardener needs only to consult them and purchase; allow 1 oz. to every square yard. Rule off a yard breadth of the lawn with the garden line; the length of this, paced out, is square yards; allocate the exact amount of seed for this; mix with soil or sand in a pail and then scatter uniformly, and rake in. Repeat with another breadth of 1yd., use the same amount of seed, and so on. Finally, rake the whole lawn evenly and roll very lightly. Protect from birds by a net, or by means of suitable "scarers." When the grass is well up, rake off stones exposed after rain, and again roll. It may also be possible to mow once before winter. Weeds of an annual nature need not be troubled about in an autumn-sown lawn as a rule, because they die down in winter and leave the lawn weed-free next spring.

A light roller only should be used for a new lawn raised from seed, and, if possible, it should be a wooden one. The first cutting should be done by hand, or with a light side wheel mowing machine with the blades set high.

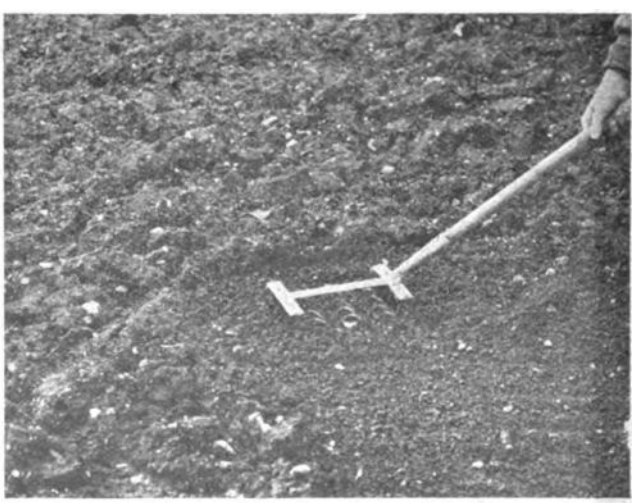
C.



REMOVING WEEDS FROM A LAWN WITH A SPECIAL WEED GRUBBER.



FILLING UP THE HOLE WITH A MIXTURE OF SIFTED SOIL AND GRASS SEED.



A USEFUL TOOL FOR BREAKING UP THE LUMPS OF SOIL AND SECURING A FINE TILTH.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

THE weather is said to be responsible for an outbreak of American gooseberry mildew in widely scattered districts of Scotland, and more particularly in Perthshire and the Midland counties. This fungoid disease may be identified by the white powdery patches which appear on the leaves, shoots and fruit in the earlier or summer stage, and as the season advances the mycelium becomes dingy brown in colour with little black dots visible on the surface. The first berries to be attacked are usually those on the shaded parts of the bushes, and the fruit not only becomes unsightly in appearance but is eventually destroyed. There is no known cure for American mildew, which seems to spread rapidly under the atmospheric conditions prevalent this season, and when once the flower-like patches make their appearance the only effective treatment is to cut out all the infested parts and burn them. As a preventative measure the soil immediately beneath and around the bushes should be turned over towards the end of the year for the purpose of burying the fallen winter spores. Some authorities also recommend spraying the bushes with Bordeaux mixture in January.

At their recent show the Dumbartonshire Sweet Pea Society departed from the usual custom of judging the decorated dinner-table competition by leaving the decision to the popular vote of the public. The experiment was an unqualified success. On entering the hall visitors were provided with a voting card which invited them to name the exhibits in the order of merit. A large preponderance of the voters placed the table of light-coloured roses first, lavender sweet peas second, and the arrangement of crimson roses third. Nobody could find fault with that verdict, which fairly represented the artistic value of the respective tables.

In our report of the Scottish Sweet Pea and Rose Society's show the exhibit of Messrs. Austin and McAslan, Glasgow, was made conspicuous by its absence, for it was one of the two trade displays which received a large gold medal award. The staging in front of the platform, which extended across the hall, was occupied by a massive collection of hybrid tea and polyantha roses, flanked by groups of ferns; while the background, composed of palms, completed a pretty decorative scheme. Newer introductions were represented by Princess Elizabeth of Greece, Duchess of York, Gynneth Jones, Mrs. Barraclouth, Norman Lambert and Golden Salmon, a new polyantha rose of charming colour.

The popular Coltness Gem dahlia has disappointed quite a number of its admirers this season by the absence of the free-flowering habit which, in the past, has been regarded as one of its valuable assets. In some gardens the plants are only coming into bloom, and in others, where flowering was much earlier, the colour display has been poor and intermittent, quite unlike the brilliant scarlet dwarf bedding dahlia with which amateurs have been familiar in the past. There is evidence that some of the stocks in the market are not true to character and that the profusion of foliage has been obtained at the expense of the bloom. As a contrast, the old favourite Geranium Paul Crampel are conspicuous for the size and number of the flower trusses, notwithstanding the unseasonable weather, and the opinion is freely expressed that fewer dwarf dahlias of the Coltness Gem type and more geraniums will be used for bedding purposes in future. This is, probably, an exaggerated view that is not justified by the experience of this abnormal season.

"You cannot grow roses in Glasgow." This remark was made, half in jest and half in earnest, by Mr. Thomson, Edinburgh, President of the Royal Caledonian Horticultural Society, at the luncheon given by the *Daily Record* to the ladies and gentlemen engaged in the judging of the gardens connected with the Corporation Housing Schemes. It was a courageous thing to say, and was as frankly confirmed by Miss Roberts, Glencarse, who confessed that she had not seen a decent rose in any of the gardens she had visited. To see ourselves as others see us is advantageous in many ways, and it is well that folks should be acquainted with their deficiencies as well as their efficiencies; but reliable conclusions cannot be formed regarding the culture of roses in Glasgow by the condition of the roses grown in housing scheme gardens, for the owners are severely handicapped in most cases by the situation and the nature of the soil. In the newly formed schemes the tenants who have recently entered into possession have had little time to improve the soil and bring it up to a state suitable to the requirements of roses. Moreover, the exceptional season must be taken into account, while the absence of bloom may be explained by the fact that the bushes were seen between the summer and autumn period of flowering. Undoubtedly, there are in Glasgow, as in other large industrial towns, districts that are not well adapted for successful rose culture; but, as Mr. John Bell reminded the company, there are lots of places within the city boundaries where good roses are grown. The personal element, too, is a factor that should not be overlooked, and once the amateurs, who are in possession of a garden for the first time, have gained experience, they will be able to improve on their earlier results. Another point: it is not in Glasgow alone that roses have been disappointing this season. I know of several country gardens where the partial failure of the roses might suggest a similar verdict, and the folks who own them have nothing to learn in the art of rose culture.

No fewer than ninety-four applications were received for the vacant post of Assistant Director of Glasgow Parks, and the subcommittee have selected the following six candidates as a short list: James W. Atkinson, Chief Assistant of Parks, Blackpool; W. J. Hepburn, Superintendent, Greenwich Park, London; W. Lamberton, general foreman, John Innes' Institution, Merton, London; Leslie E. Morgan, General Assistant, Parks Department, Manchester; George E. Roden, Superintendent of Parks, Folkestone; and W. A. Watson, Assistant Superintendent of Roe Lee Park, Blackburn. A motion that four additional applicants on the staff of the Glasgow Parks Department be added was defeated in committee by 10 votes to 7.

Miss Whyte, Barnhill, has presented a solid silver cup to the Dumbartonshire Sweet Pea Society for competition in the amateur classes, to take the place of the cup won outright this year by Mr. George Blackie.

ST. MUNGO.

FLOWER SHOW FIXTURES.

September 7-8.—Glasgow and West of Scotland.

September 9.—Dalry.

September 10.—Avonbridge, Barrhead, North British Locomotive, Springburn and Cowlairs, Haddington, Kilbarchan, Moffat, Singer's (Dalmuir).

September 14-15.—Royal Caledonian, Edinburgh; Scottish National Union of Allotment Holders, Edinburgh.

September 16-17.—Springburn Northwestern; Hutchesontown Chrysanthemum.

WHAT OUR READERS SAY

THE BLUE MARGUERITE.

SIR,—Agathea coelestis, popularly known as the blue marguerite, is one of those useful subjects for the cool greenhouse which, with simple treatment, may be had in flower practically throughout the year. The plant is allied to the cineraria, and succeeds with similar care, although it is even of more easy culture. A compost of loam, leaf-mould and sand should be employed, and it is rather an advantage to let the plants be somewhat pot-bound, for in this state they are much more likely to continue in bloom. Propagation is carried out by means of cuttings, which may be rooted in the spring or autumn in light soil. Those struck at the present time may be brought into flower in the early months of the year. The blue marguerite is of neat habit and forms compact little bushes thickly strewn with the sky blue daisy-like blossoms. After a specimen has been in flower for some months it may be cut back rather severely, when it will shoot again with great vigour. The plant is a perennial, although it is a good plan to raise a few new specimens from cuttings each year. —L. B.

PROTECTION OF PLANTS, ETC.

SIR,—I have used an emulsion made of paraffin and soft soap for the above and find it very useful for all kinds of vermin on chrysanthemums, etc., but I think there is too much paraffin in the recipe that you published in THE GARDEN recently, which I think will burn the foliage of the plants that are sprayed, and there is not enough of soft soap. I send you the following recipe which I have found efficacious, and which kept at bay numerous insect pests in my garden: 3 pints of rain water, 12 ozs. of soft soap, 3 quarts of paraffin. Bring all to the boil. Use at the rate of one part paraffin emulsion to twenty parts of water. —P. S., *Fife*.

A JULY-FLOWERING GENTIAN.

(*Gentiana Lagodachiana*).

SIR,—This July-flowering gentian is a particularly charming plant of its family, very easy to cultivate and can be relied upon for a prolific annual blooming. It sends out long red-brown stalks from a neat centre; the trumpet-shaped flowers, soft sky-blue in colour, are in loose clusters at the extremities.

Your readers may like to do intentionally with this satisfactory gentian what I did accidentally in my rock garden. The plant happened to be in the centre of some flat pieces of stone about 2ins. high, outside which were patches of silvery achillea. The gentian sent its recumbent stems over the stones so that its blue flowers lay upon the silver bed, enhancing their beauty and protecting them from soil-stain in wet weather.

Raoulia australis would, perhaps, make a still more beautiful grounding for the gentian. —G. H.

CLASSIFICATION OF DAFFODILS: ERROR IN NAMING.

SIR,—I have just had the opportunity of perusing the classified list of daffodils, 1927, issued by the R.H.S., and wish, in justice to the memory of the late Mr. A. E. Lowe, to correct an error appearing in it with reference to the variety "Silver Plane," there bracketed with the name of Mr. Cranfield.

This variety was well illustrated in the Midland Daffodil Society's Annual Report for 1925, and on page 9 the information is given: "*Silver Plane*, shown by the *Donard Nursery Co.*; this is a New Zealand seedling, raised by the late *Mr. A. E. Lowe* of Otahuna."

Mr. Lowe was for many years head gardener to Sir R. Heaton Rhodes of Otahuna, Christchurch, N.Z., and one or other of these gentlemen should in the list, be given the credit for raising this plant, described in the M.D.S. report as "the most distinct flower in its class."

I may add that this past summer and autumn here have been very favourable to our parks, and hydrangeas and cannas in particular have made a wonderful outdoor display. The hydrangeas are only now finishing their second crop of bloom, though we are well into winter, and have had two or three white frosts quite unusual for us. I enclose a little photograph of a bed of cannas in Albert Park, one of our city gardens, which you may think of interest to readers of THE GARDEN.—A. E. GRINDROD, *Mount Eden, New Zealand.*

A FINE BED OF CANNAS IN A NEW ZEALAND PARK.

THE RESERVE GARDEN.

SIR,—I feel sure that many amateur gardeners do not fully appreciate the value of a reserve garden. Even in a small place there should always be some kind of reserve garden. This might be in a corner of the kitchen garden, and here seedlings and cuttings can be raised. The reserve garden may be used as a kind of nursery where young plants and rooted cuttings can be given a chance to get up their strength before being removed to permanent positions in the main garden. New plants that have been purchased can profitably be given a spell in the reserve garden where they can receive a little special attention and be brought into a more presentable condition. The most convenient form for a reserve garden will be a square or oblong which is laid out in parallel beds 5ft. or so wide, so that the plants can be easily hoed and weeded. The paths need not be more than 18ins. wide, just enough to give space to walk between the beds and attend to the plants. Such beds need never be idle, for if not actually wanted for growing on young stock, can be planted with annuals and perennials to produce flowers for cutting. Another purpose of the reserve garden is to accommodate plants that have done their work in the spring border. After division, daisies, aubrietias, forget-me-nots, etc., can be started in the beds in a new career. Then bulbs which have been lifted before the foliage dies can be put into the reserve garden before they are finally taken up to ripen off.—H.G.

THE SOVEREIGN OF ROCK GARDEN SHRUBS.

SIR,—An able critic of alpine flowers once said that "Dryas octopetala is the sovereign of all shrubs for the rock garden," and it is difficult indeed to controvert the remark without a departure from the truth, unless one is specially swayed by love for other subjects. But the sight of a small plant only would make it hard to agree with the verdict, and it is only when we see D. octopetala in a spreading sheet of its lovely oak-like leaves, thickly covered over in summer—especially in June—with cream white flowers of large size, which are borne on 2in. stalks, which eventually develop in length until they are 4ins. to 6ins. long, when the silvery seeds are produced. D. octopetala is really lovely when spreading into masses a yard or two in diameter, and I think it looks specially pleasing when hanging over a sloping bank. It is a real sun-lover, but fails to flower freely in some gardens owing to the absence of lime, and I have seen plants immensely improved by working a top-dressing of old mortar among the branches. It may be raised from seeds, but they are of slow growth, and cuttings root satisfactorily in sand in autumn. Old plants may also be layered, so that roots may be emitted from the branches and then these taken off when rooted.—S. ARNOTT.

OUR PHOTOGRAPHIC COMPETITION

Readers have little time now in which to take photographs for our competition which closes with the issue of September 17th. We hope that early September will provide better opportunities. It may be impossible to publish immediately all sent in, but we shall introduce, from time to time, into our pages all suitable pictures, and make awards on the same conditions as those gained in the competition.

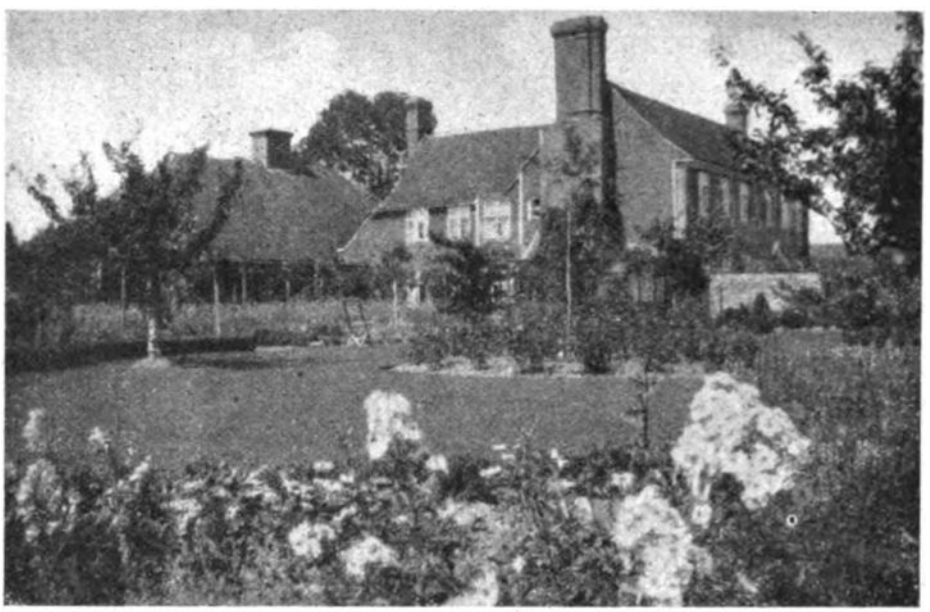
This photograph shows part of my iris garden, where countless Japanese irises flourish. Many varieties have been planted, including shades of mauve, white, deep purple and blue. Here, in New Zealand, the irises begin to flower early in December and continue for over two months, and sometimes they grow to a height of 4ft. 6ins. to 5ft. They are planted at the edge of and surrounding a shallow natural pond.

The guinea photograph, sent in by MISS D. H. BROWN, *Mount Thomas, Canterbury, New Zealand.*

Digitized by Google

I took this photograph of a corner of my cottage garden during last May when the tree peony was in flower and had over twenty blooms on it. This peony made a very pretty picture with the old apple tree in full blossom beyond; while in February and March the garden was gay with crocuses and daffodils of every kind, all of which I plant out after flowering in my greenhouse. MISS C. M. GIBSON, *Newick, Sussex.* Award of 5s.

A well grown yucca makes a splendid subject for the centre of a carriage drive. This specimen has eight flower spikes this year, rising to a height of over 10ft. The plant measures about 8ft. in diameter and is surrounded by rockwork, planted with aubrietias, saxifragas, etc., making an extremely effective display.—B. H. BALLS, *Cambridge.* Award of 5s.



From early spring until late autumn there is always something of interest in this garden. First come the crocuses and daffodils, and then the standard fruit trees are smothered with bloom. After the tulips, the roses, in large circular rose beds, begin to come into flower, and later phloxes, pentstemons and numerous other hardy plants brighten the mixed border which can be seen in the foreground. MRS. W. WELLER, *Tenterden, Kent.* Award of 5s.

When planning this garden I found the ground sloped considerably. At the end of a level lawn this wall was built of old red bricks and large flints. Each year, aubrietias, perennial candytuft, rock roses and many other plants form a mass of colour. MISS E. ROBERTSON, *Longfield.* Award of 5s.

This little lily pool and rockery are made in a town garden. The work was started in March this year and the rock plants have done very well for the first season. Raspberries and loganberries screen the pool, and the small lawn is edged with violas. J. H. STOCKIT, *Halifax.* Award of 5s.

FRUIT AND VEGETABLES

September in the Vegetable Garden.

THE August sowings of colewort, lettuce, etc., will be ready to plant out. This may be done after rain or during dull weather. Cabbages and cauliflowers may be pricked out for spring planting. The cauliflowers may also be put in a cold frame or in a square bed that can be covered with a frame when hard weather sets in. By all means let the plants have as much air as possible except when there is frost.

Earth up celery and leeks while it is dry, and tie up lettuces and endives. Thin out any crops where the plants are too numerous, and lift those early vegetables that are ready for storing. Onions and early carrots may be lifted and stored when they are moderately dry.

Potatoes do not keep any better in the store clamp if not lifted when they are ripe. It is always an advantage to dig the potatoes during dry weather. If tubers are wanted for seed, it is a good plan to lay them out in the sun for a day or two before storing. Only the seed-sized tubers should be exposed in this way. To "green" table potatoes is to spoil them; nay, render them poisonous as well as unpalatable. Eating potatoes should never be exposed to cold winds at lifting time, nor be stored in a draughty shed, because they turn bitter. Put them into a clamp, cover with straw and earth; or place in bags or boxes, etc., in a dark cellar or shed beyond the reach of frost.

Seed potatoes may be put into the sprouting boxes at once and stored thus. They should be picked over now and again and any unsound tubers thrown out. A decaying tuber will spoil the others in contact with it. It is important that the skin be not ruffled or broken in course of lifting or handling. Greening in the sun makes the skin of the tubers tough; but they must not be left out of doors uncovered if there is any frost by night. Mats or straw may be spread over the greening potatoes at sunset.

Plant up ground now being cleared of ripe crops with such vegetables as borecoles, cabbages, leeks, etc. Sow prickly spinach for winter use. A sowing of onions may even yet be made if there is an available space in a sunny border.

Plant out the main crop of cabbages in rows about 2ft. apart and 1½ft. between the plants. Give the ground a good soaking with very weak liquid manure if it is dry.

Gather late peas and beans when young, and give copious drenches of liquid manure to stimulate the production of fresh pods. This tip is worth a lot, and the peas may be kept green until caught by frost.

Clear off old crops of peas, cabbages, etc., and trench the ground.

Jerusalem artichokes and beets should be lifted just as required, even during the winter months, but a mulching of littery material should be spread over the rows to keep out the frost. Saladings, like radishes, mustard and cress, should now be sown under glass or in a south border where hand-lights may be put over the beds in the event of an early frost.—J. W.

Earthing-up Winter Greens.

WINTER greens have made much growth during the past few weeks owing to the dull, wet weather. It is the hard-stemmed plant that withstands the severe winter best. To help the soft-stemmed ones, and even those more matured, earthing-up is advisable. The earthing is done much the same as in the case of potatoes, and the work should not be delayed or roots will be damaged when the soil is disturbed. Furthermore, the work cannot be done as well when the whole space is covered with big leaves. Those plants not very much advanced may be assisted by one application of 1 oz. of sulphate of potash per square yard before the soil is drawn up to the stems. Sprinkle the sulphate very evenly on the soil, keeping it away from the stems of the plants. Then draw up the soil so that the stems, if possible, are buried right up to the base of the lowest leaves. Firm the soil by treading before the earthing is done, and again afterwards if the soil drawn up is naturally light. But do not tread down heavy soils, allow them to settle gradually. All blind plants should be drawn out and replaced with healthy ones. If left in they would be useless and rob the good ones, too.—HANTS.

Strawberries.

OLD strawberry plants are not profitable. Considering how freely the plants of most varieties produce nice, strong runners, it is bad policy to retain the old ones beyond three years. Some cultivators treat the strawberry plant as an annual, raising rooted runners and planting them every autumn. The plants are planted out 18ins. apart each way. Expert cultivators can succeed well and some amateurs may. It is well worth while trying a few plants in this way. But the main object of this note is to induce cultivators to scrap all three year old plants and replace them with newly rooted runners, not, however, on the same plot, but on one previously occupied by a totally different kind of plant—preferably potatoes. The plants should be 18ins. apart in rows 24ins. asunder. Deeply dig the soil first and enrich it with rotted manure if it is poor. The best time to work the soil is when it is moderately dry, as then it can be firmed again a little after the digging. Rich soil need not have any manure added to it now; a surface mulch after planting and one again in spring will be sufficient. When an autumn mulch is put on care should be taken that the crowns of the plants are not buried under it for any great length of time, or the crowns so covered up will decay and eventually rot away.—CHRISTCHURCH.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful and interesting hint sent in by a reader. Five shillings will be paid for all others published. Payments for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF-GUINEA HINT

Economising Space in a Small Garden.

In a garden where space is limited and it is desired to grow spring flowers (such as daffodils or narcissi, which can be left in the ground), I find it a good plan to plant the bulbs in clumps, marking the position with labels or sticks, so that the surrounding ground may be dug without disturbing them. In the spring, sweet peas or other tall-growing annuals, such as lavatera, can then be sown in circles outside the bulbs. If the annuals require staking before the spring flowers are over, short twigs will provide temporary support, the pea sticks being put in position later. The unsightly appearance of the dying foliage will thus be hidden—an additional advantage.—C. W.

Mignonette for Winter.

For late blooming, seed of mignonette may be sown now in the pots where the plants are to flower. Use good loam, sand and manure, adding also a little charcoal and crushed lime scraps. Sow thinly on the surface of the soil, which may previously be watered. Cover the seed lightly, and stand the pots in a frame. Shade from the sun until the seed germinates. After that, expose freely to light and air. Thin out the seedlings 1in. apart, eventually leaving five or six in a 6in. pot. Water carefully and give the coolest possible treatment all through the early stages. On the approach of sharp frosts, transfer the pots to an airy shelf in the greenhouse.—A. J.

Bulbs in Bowls.

One potent cause of failure with bulbs grown in bowls is that the fibre is not properly moistened in the first place. When dealing with small quantities, a bucket may be half filled with the fibre, then rain-water added to fill the bucket to the top. In a few hours the fibre will be found to have absorbed all the water, and though in this state it is probably too wet, it is an easy matter to squeeze out all superfluous moisture with the hand. The right condition is attained when only a few drops of water fall out when a handful is squeezed. With larger quantities, it is more convenient to soak the whole sack of fibre in a tub of water for some hours, letting it drain a day or so before using.—B. D. S.

When Making a New Lawn.

There are probably a number of gardeners who, intending to put down a new lawn and unable to afford the cost of turf, will sow seed this September. It is a good plan to obtain sufficient turf to edge the site of the lawn and then to seed the remainder, after, of course, making up the ground to the level of the top of the turf. A firm edge is thus obtained without using boards or tiles to retain the earth. I find that this is also a great aid in obtaining a level surface for sowing, particularly if the proposed lawn is fairly large.—E. C. E.

To Get Rid of Wireworms.

Wireworms are very destructive pests, especially in summer, when they attack all kinds of root crops. A favourite food of wireworms is potatoes, and you can turn this liking to good account in getting rid of them. Get some old tins, pierce the sides with holes made by a bradawl, attach a wire handle, then fill with potato bits or peelings. Bury these traps in the garden, and pull them up in a month's time. They will be found full of wireworms, which you can then destroy. This is a most efficient way of getting rid of both wireworms and millipedes, as the pests scent the food from quite a distance away, and soon find their way to the traps.—M. J.

Raising Anemone Coronaria from Seed.

Mix the seed well in moist sifted soil, put in pots and lightly press down. Directly germination takes place, sow thinly in pans or boxes of soil free from worms—the coarse soil in the bottom of the pan—place some old sacking on this, then some fine soil, sow on this and press lightly with the hand. Keep moist. Directly they come up sprinkle with fine soil lightly. The sacking makes a perfect drainage. The seed germinates in about three weeks. I have been very successful with the above method. Transplant carefully in open ground when large enough to handle.—J. H. A.

THE GARDEN

VOL. XCI.—No. 2910. SEPTEMBER 10, 1927. PRICE TWOPENCE.

BULBOUS IRISES FOR GARDEN DECORATION

IT is a matter for regret that this section of the great iris family does not appear to receive the attention it deserves, considering the ease with which the various types may be grown, their inexpensiveness, and their usefulness as flowers suitable for garden decoration or as cut bloom. With these strong recommendations in their favour, the bulbous irises are very obviously flowers for every garden, be it large or small.

It is advisable to obtain supplies and plant as early as possible, although bulbs planted as late as December will give good results.

The Spanish irises are very cheap, and make a splendid show of bloom during that "between the seasons" period which occurs in June, after the spring flowers have ceased to be attractive and summer flowers have not yet attained their best. They may be planted in nursery lines, consisting of double rows 1ft. apart and allowing 3ins. or 4ins. between the bulbs if they are required for cut bloom. Plant so that the noses of the bulbs are 3ins. below the surface of the ground. For garden decoration, clumps of twenty or twenty-five bulbs, planted in the border, are most attractive; while as subjects for filling flower-beds they are equally as useful. Planted with pansies or violas as a groundwork, they make a splendid early summer show; and if gladiolus corms are planted in between the irises in the spring a succession of bloom is maintained. When grown in beds or borders, a distance of 5ins. or 6ins. may be left between the bulbs. After flowering, the foliage should be allowed to die down naturally, and the bulbs will thrive and multiply from year to year. Although not fastidious, they prefer a rich, rather light soil, and in exposed situations they should be afforded some protection from cutting east winds. When the flower stems appear, bi-weekly applications of dilute manure water are exceedingly beneficial. Every third year the bulbs should be lifted as soon as the foliage has faded, sorted according to size, and replanted after the ground has been deeply dug and enriched with applications of well rotted manure and some bone-meal. The smaller bulbs may be planted separately in nursery rows, where they will quickly attain flowering size. It is a matter of opinion whether the best effect is obtained by planting the various colours separately or mixed together. In the border, clumps of one colour only are to be preferred; but a good bed of mixed Spanish irises forms a most attractive feature during its blooming season. The bulbs may be obtained either mixed or in named varieties.

By planting some English iris a succession of these bulbous irises is maintained, for these English irises come into bloom a fortnight later than the Spanish kinds. They are more vigorous growers, but are equally as hardy and easy to cultivate. Plant them at the same depth as advised for Spanish iris, but a little more room between the bulbs may be allowed with advantage. Although more limited in range of colour, there are at least fifteen or sixteen worth-while varieties.

The Dutch iris is of more recent origin, and is somewhat more expensive to purchase than the other classes. It flowers a fortnight earlier than the Spanish iris, which it resembles except for the fact that the flowers are larger; it can be obtained in an equally fine diversity of colour. A distance of 5ins. or 6ins. should be allowed between the bulbs when planting.

Although a rather light soil has been advised as preferable for these flowers, the possession of a heavier medium should not deter one from planting bulbous irises, for with deep cultivation and the addition of any material tending to increase the porosity of the soil excellent results are obtainable. The fact that these irises are gross feeders should always be borne in mind, and an adequate supply of suitable food material incorporated with the soil prior to planting, unless the soil is naturally very rich.

Housing Greenhouse Subjects.

IT will soon be time to think of bringing into the greenhouse all those plants which have been given a holiday in summer in the open. Before the plants are removed, pick off all broken stems, dead leaves, etc., and then spray them thoroughly with soapy water, slightly warm, or with insecticide; this last essential ensures that all pests or potential pests are removed and that the plants are taken into the greenhouse in a clean condition. To the same end, clean out the greenhouse and, as a last point, scrub the pots down with an ordinary scrubbing brush and hot soapy water. All summer shading matter may now be washed from the greenhouse roof, every effort being made to give the plants ideal winter quarters. When the plants are once inside, remember that a close, stuffy atmosphere will lead to trouble. Ventilate at first to the very utmost possible, and so avoid a sudden plague of insect pests, an outbreak of disease or a most annoying leaf-dropping. Even at night admit some air. Water with care, giving less and less water as the season advances, and what has to be given should always be applied early in the day, and discard old plants unlikely to give much satisfaction, in order to make room for fresh and more robust stock.

This Week's Work

For Gardens in the South and Midlands.

Thin out shoots of dahlias and feed the plants with liquid manure.

Prick out cabbages and cauliflowers sown last month.

Earth up celery and leeks and lift early onions.

Continue potting up hyacinths and narcissi.

Sow onions and winter spinach in drills.

Gather apples and pears when ripe.

Disbud early-flowering chrysanthemums.

Propagate bedding plants of all kinds.

Sow hardy annuals in the open.

Finish planting out strawberry runners.

This Week's Work

For Gardens in Scotland and the North.

Sow sweet peas in pots or boxes.

Pot rooted cuttings of pelargoniums.

Remove late-flowering chrysanthemums to the greenhouse.

Prepare cold frame for cuttings of calceolarias, penstemons and antirrhinums.

Continue to plant up strawberry beds.

Take cuttings of fuchsias.

Transfer a few parsley plants to a frame for winter supply.

Begin planting daffodils and hyacinths in beds and borders.

Lift and divide herbaceous plants that are out of bloom.

Pot up a few chrysanthemums from the open ground.

Propagate catmint by cuttings.

HOW TO GROW FINE PÆONIES

Herbaceous pæonies are among the most beautiful of our hardy flowers; their requirements are simple, and there are few gardens in which they may not be successfully cultivated.

FEW of our hardy flowers are as beautiful as herbaceous pæonies, combining as they do handsome foliage and beautiful flowers with a wide range of form and colour, varying from pure white, through varying shades of cream and creamy yellow, through rose, pink and red to deep crimson. Their culture presents no difficulties, and in addition, many of them are deliciously fragrant.

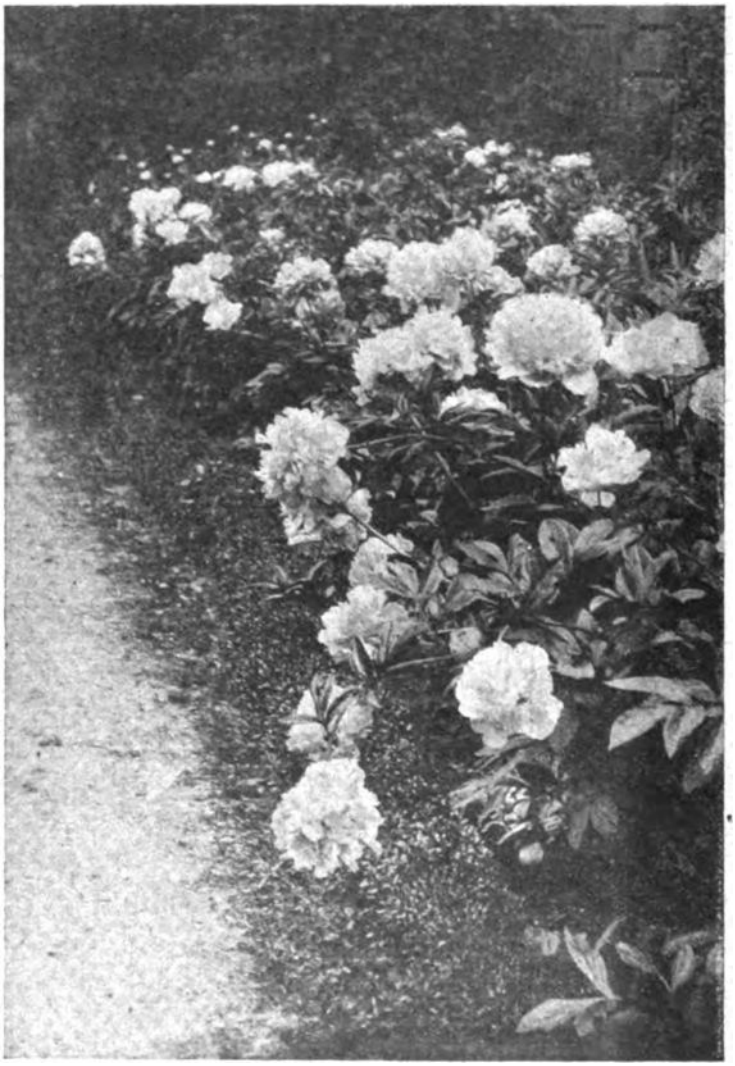
Position.

In this respect they are very accommodating, as they may be grown in beds or borders by themselves, and where large collections are cultivated they are usually done in this way. This system has its disadvantages, as their flowering period is rather short, and one is left with a long, flowerless period in that particular part of the garden. This difficulty can, however, be got over, as I shall presently indicate. Apart from large special collections, pæonies can be used to advantage in various parts of the garden, either for grouping in the mixed border or for planting in clumps or masses along the margin of shrubberies; or they may in many cases be used with excellent effect in the semi-wild parts of the garden or in the hardy fernery. They are specially useful for such positions, as they do not mind partial shade. It is, however, wise to choose the stronger growing varieties for such positions. In such situations the brighter-hued varieties are most effective, especially when one is planting for distant effect. For such positions the old-fashioned double red pæony of cottage gardens is perhaps as effective as any, as it is a strong, robust grower and succeeds perfectly in partially shaded situations. The brilliant-coloured young growths of pæonies are also an attraction in the earlier stages of their growth, and when associated with daffodils the effect is very beautiful. This brings one to the consideration of plants that may be grown with pæonies to furnish a display when the latter are out of flower.

Plants to Associate with Pæonies.

In addition to some of the strong-growing varieties of daffodils, such as Sir Watkin, Empress and Emperor, which may be interplanted with pæonies to furnish a display during the early part of the season, there are several other bulbous and tuberous-rooted subjects that may be successfully used for this purpose. Gladioli in their many beautiful varieties are most useful, and they may be grown quite well in this way, especially if the pæonies are not planted too closely together, although it is surprising how well they do even when they have to push their way up through the foliage. Strong-growing varieties are, of course, to be preferred for this purpose. Hyacinthus candicans is a fine bulbous plant which is useful. Where there is large planting of pæonies and a second display is required, there is no reason why they should not be interplanted with groups of some of the free-flowering varieties of kniphofias; they would also give a furnished appearance to the beds and borders during the winter.

In the herbaceous border it could be arranged to plant alongside of them some slender-growing herbaceous plants, the shoots of which could be trained partly over the clumps of pæonies. Some of the slender-growing varieties of Michaelmas daisies might be used.



PLANT YOUR PÆONIES NOW.

Cultivation.

As already indicated, the successful cultivation of this class of pæonies presents no difficulty, as they grow well in a variety of soils and positions. They, however, prefer a good, rich, moist loam. When preparing the sites for them it is important that the ground be thoroughly cultivated, as they dislike frequent disturbances, and usually take about two years to recover from transplanting. The ground should be trenched two spits deep, at the same time working in plenty of well decayed farmyard manure: this is important, and at no time should green manure be used, especially for surface dressings, as this is undoubtedly a fertile source of infection for pæony disease. Heavy wet soils may be improved by the addition of opening, gritty material. The planting sites should also be given a dressing of lime or basic slag, applying the latter at the rate of 6 oz. to 8 oz. per square yard. A dressing of bone-meal may also be applied at the same rate.

When planting, they should be given plenty of room, remembering that in time they make large clumps, also having in mind the fact that you may wish to interplant them with some bulbous subject. Generally, 4ft. apart may be regarded as a good distance to plant. When well established they enjoy yearly dressings of well rotted manure, and when the flower buds show they may with advantage be watered with dilute liquid manure. When the clumps get large and give signs of losing vigour it will be necessary to lift, divide and replant them, if possible on a new site. Failing new ground, the old sites must be thoroughly trenched and manured.

Pæonies for Cut Flowers.

They are in many ways ideal for furnishing a supply of cut flowers, their range of good colours and delicate perfume rendering them specially useful for this purpose. They also pack and travel well, and for this purpose can be cut in bud. Cut in the bud and tightly wrapped in grease-proof paper, they travel well in cold storage. The single varieties are very beautiful for decorative work, but do not last so well as the double varieties. Where they are required for a supply of cut flowers they are best grown in the kitchen garden, or in beds or borders in the reserve garden.

Diseases.

Pæonies are subject to attacks of a species of botrytis, which has been called B. pæonia, and often proves very troublesome in collections. The young growths become black and gradually shrivel. If they escape at this stage the flower buds are often attacked later on. There is no doubt but what green manure, especially when used as surface dressings, is a fertile source of infection, and for this reason should not be used. All affected shoots should at once be removed and burned. The surface soil may also be removed and replaced with fresh loam. If the plants are sprayed with a solution of liver of sulphur at the rate of 1 oz. to 3 gallons of water it should act as a preventive.

Varieties.

There are so many varieties that it is very difficult to give a selection, and it is best to see a collection in flower and then make a

Digitized by Google

selection of the desired varieties. The following short list, however, includes varieties that the beginner may safely plant, *viz.*, Asa Gray, pale lilac; Boule de Neige, white; Couronne d'Or, white, inner petals tinted carmine; Duchesse de Nemours, white, primrose centre; Duchess of Teck, creamy white; Felix Crousse, flame red; Mme. Jules Elie, pink; Mme. Moreau, pink, blush white centre, fragrant; Marie Lemoine, white, creamy centre; Mons. Ch. Leveque, rosy salmon; officinalis rosea; officinalis rubra, old double scarlet; Rubens, dark crimson; Sidonie, pink blush centre; Philomene, rose pink; and albiflora grandiflora, single white, scented: this is a very beautiful variety and should certainly be in every collection.

Other fine varieties include Sarah Bernhardt, a late-flowering pink variety; Lady Alexandra Duff, a beautiful white pæony which is tinted in the young stage with delicate pink; François Rousseau, a brilliant velvety red; Kelway's Betty, a sweetly scented cherry red, a lovely colour; Marconi, which has large pure pink flowers with yellow anthers; and Baroness Schröder, with its enormous flowers of blush white.

There are a number of beautiful single Chinese pæonies, all varieties of P. albiflora, and among these are Sir Visto, a large flower shell-pink pæony, opening to a delicate blush, which is one of the best for cutting; the Bride, a profusely blooming snow-white variety; and the tall-growing Victoria, which bears handsome brilliant crimson flowers.

Some of the hardy double European May-flowering pæonies are particularly suitable for shady situations and north borders; they are varieties of P. officinalis.

K. E.

A WELL-ESTABLISHED CLUMP OF A GOOD DOUBLE VARIETY.

SMALL BULBS FOR POT CULTURE

Snowdrops, crocuses, scillas, chionodoxas and many other small growing bulbous plants can be grown in pots and are excellent for decorating a room or greenhouse.

FEW gardeners realise the value of some of the smaller kinds of bulbs for pot culture. Many of these are quite inexpensive and, in their way, will give as fine a show as the more widely grown hyacinths, tulips and narcissi. Pots of crocuses, for instance, are without rival for the decoration of room and greenhouse, especially if care is taken to select varieties specially recommended for indoor culture. The bulbs will grow well in any light common soil. Pans or bowls may be employed instead of pots and, where there is no drainage, fibre should be employed instead of soil. Give the bulbs a chance to root well in some dark place, or, better still, bury the pots in dead leaves, fibre, sand or similar material. The crocuses can be taken out in batches as required, and in this way a fine succession of blossom is secured.

Of course, nothing in the way of forcing is required. Chionodoxas and scillas may be treated in much the same way, five to seven bulbs being grown in a 48-sized pot. With early planting and a good rooting period, these bulbs may easily be brought into full beauty about Christmas-time, when they will be very much appreciated. Both these bulbs can be grown in fibre but better results are usually secured when they are grown in pots of soil with a free drainage. Snowdrops are easily brought into flower in time for Christmas if care is taken to select the right kinds. The common sorts, most often seen in gardens, are not good pot subjects, but splendid results are secured with the giant snowdrop (Galanthus Elwesii) and what is, perhaps, the best variety of all, Sutton's Winter-flowering. Give the snowdrops a chance to root well before encouraging the growth of the shoots by exposure to light.

In mentioning the foregoing one does not by any means exhaust the list of small bulbs suitable for pot culture. In looking over the bulb catalogues it is worth while considering the purchase of some, at any rate, of the following. A charming little anemone for flowering just after the turn of the year is A. blanda Ingramii. Here the flowers, which are of a bright blue colour, are produced in great abundance. Pot up in any light soil and keep in some sheltered place out of doors until the late fall, and then bring indoors. Some of the little irises suitable for winter culture are rather expensive, but it may be pointed out that I. pavonia and I. tingitana are quite a reasonable figure. With early potting the latter can easily be had in bloom by Christmas.

Not many people think about growing fritillarias in bowls of fibre, but, with simple treatment, these do extremely well and produce their quaint flowers in profusion very early in the New Year.

THE BLUE-FLOWERED GLORY OF THE SNOW (CHIONODOXA LUCILLIÆ).

Lachenalias also deserve to be more widely grown, and of these L. pendula is especially to be recommended. This plant has large, bright red flowers which are extremely showy.

By potting up these bulbs at once it is quite easy to have the plants at their best in time for Christmas. Several species of oxalis may, with protection and, if possible, a little heat, be induced to flower at a very early date.

Special mention must be made of O. adenophylla, which has rosy pink flowers and finely cut foliage; O. Bowiei, with crimson flowers; and O. rosea. Sutton's Golden Cup is a glorious yellow variety which, with the simplest treatment, flowers on a most lavish scale.

L.B.

A SIMPLE MORAINE AND HOW TO MAKE IT

This part of the rock garden can be easily made, and many of the choicer rock plants prefer it.

THOUSANDS of choice rock plants are killed by mistaken kindness annually, simply because they are treated too generously, being planted in deep rich soils, which do not give them the acute drainage that is an absolute necessity. All the little mountain gems flourish in very rocky places, sometimes making a congenial home in the merest fissure in the rock, and at other times being found quite happy on a natural moraine or a heap of scree containing no true soil but just some rooting material here and there made up of finely powdered rock and the peaty remains of dead plants. A tiny subject only a few inches in height will send its roots to a depth of 2ft. or 3ft. among the rocks seeking moisture and food.

The production of somewhat similar conditions is quite necessary as an aid to success in growing many of the plants that come from lofty altitudes. The term "moraine" may seem to suggest an elaborate and expensive construction, but one can be made quite easily and cheaply.

It may be well to say in passing that a little moraine is a delightful feature in a garden where there is no room for a large rockery. The moraine should, if possible, be arranged so as to look like a natural part of the rock garden. The best place for it is just below a high bed or bank of rock, from which it falls away like a slope of scree at the foot of a precipice. It can also be arranged as if it were a dry river bed sloping down between two rocky ridges; and, when it is necessary to make it as an independent feature, large rocks may be laid down to form the retaining sides, and these would also accommodate some interesting plants. It is possible to make a moraine on the general level of the soil, but for my own part I prefer to have it well above the level for the sake of perfect drainage, and to have it gently sloping towards the south.

A CLUMP OF SILENE ACAULIS FLOURISHING IN A WELL-DRAINED SITUATION.

ARMERIA CÆSPITOSA, A DAINTY THRIFT FOR THE MORAINE.

Working on the simple plan of what is usually termed "dry moraine," it is desirable to have 10ins. or 12ins. of rough hard material at the bottom to form perfect drainage. This may be composed of fairly large pieces of rock, broken bricks, flints, or even large stones dug out of the garden will serve the purpose, and on the top of this rough material should be laid 2ins. of finer stone or gravel to prevent the soil from filtering down among the drainage.

Then comes the question of "soil," and on this leading authorities will never agree. For my own part, I like the upper 10ins. or 12ins. to be formed of at least half-broken rock and half soil, the soil being made up of good loam with a moderate addition of leaf-mould and sand. For the sake of economy fine gravel or any ordinary stones can be used in this part. If gravel is used, it must be quite free from clay.

If any number of plants are to be grown that are fond of limestone, it is helpful to fill in part of the moraine with broken limestone, but a few handfuls of old mortar rubble will usually supply all that these plants need.

Then the work should be finished with a 2in. layer of fine rock chippings, and it is well, for the sake of harmony, that these should be similar in colour to the rock used in the surroundings.

Another important point is to have a few rather bold pieces of rock rising out of the moraine, for they relieve its flatness and some little plants will ramble over them.

A tiny moraine can easily be made by simply laying down four large rocks, having the lowest one towards the south and filling up the space between as recommended above. An ordinary pocket on the rockery can also be treated in the same way, for with 6ins. of drainage and 9ins. of "soil" it will make a good home for some difficult things. Later experience has taught me that nearly all our rock plants do better if given more stone and less soil, for I secured for my own rock garden some alluvial soil that had about an equal quantity of small stones mixed in it, and the result has been most satisfactory.

The "wet moraine," a somewhat complicated structure, cemented at the bottom and sides and always having water at its disposal, is a luxury that has its uses, but gives few advantages over its dry rival. Choice plants are always supplied in pots, and the balls of soil can be safely put among the scree, or a little soil such as the plant loves can be mixed in around it to give it a good start.

Plants for the Moraine.

It is not desirable to fill the moraine excessively full of plants, for a portion of the rock chippings showing up here and there will prove a dainty relief to the foliage and flowers. Nor is it desirable to plant in a muddled way with just one plant of a

Digitized by Google

species. With some new or rare plants it may be only possible to obtain a solitary specimen, but others that are easily obtainable may well be planted in groups. It is well to avoid any plants that grow too strongly, especially the coarser linarias, for these, spreading by underground stems, will soon take complete possession of the whole moraine to the destruction of the choicer subjects for which it was made.

All the saxifrages of the Kabschia section are very much at home in the moraine, and its perfect drainage helps to keep the flowers in perfection for a longer period. The quickly spreading S. apiculata and S. a. alba also will do well enough in an ordinary pocket if well drained, and it is best to save the moraine space for such gems as S. Burseriana major, S. Elizabethæ, S. Faldonside, S. Irvingii and many others. The oppositifolia section are all useful for the moraine, and the Wetterhorn variety is a gem whose large flowers are a perpetual surprise, coming as they do on such minute growths.

If Gentiana verna or any of the smaller gentians prove difficult elsewhere, it is well to try them in the moraine, putting them in the lower part, where they will not be likely to get too hot and dry.

Other good subjects are all the smaller androsaces, Armeria cæspitosa, Asperula suberosa, Campanula arvatica, C. excisa, C. Waldensteiniana, C. Zoysii, Dianthus alpina, D. neglectus, the drabas, Gypsophila cerastioides, Leontopodium alpinum, Linaria alpinum, L. a. rosea, Myosotis rupicola, Omphalodes Lucilliæ, Papaver alpinum, the smaller pentstemons and potentillas, Raoulia australis, Silene acaulis and its varieties.

This is by no means an exhaustive list, and it merely indicates some of the most useful and interesting subjects. Any plant that has proved difficult or a failure on other parts of the rock garden should be given a trial in the moraine.

In spite of its acute drainage, this simple style of moraine does not dry up very quickly, for moisture will be retained among the stone even in the driest weather, and a bulk of stone is much cooler than soil. Watering may be freely done in the evening or early morning, and if any little things in bloom are likely to become draggled by watering it is easily possible, given a fair surface of rock chippings, to pour water between the plants without wetting their flowers and foliage. T. H. W.

SOME CHOICE NEW ZEALAND DAISY BUSHES

OF the many handsome New Zealand olearias grown in the British Isles, there are two or three of outstanding merit which deserve to be in every collection of choice shrubs in the milder districts of Britain.

Olearia insignis is a most striking low-spreading bush. It has large, thick, leathery leaves, as a rule 5ins. to 6ins. long and 3ins. wide, both sides of which, when young, are white, but the older leaves retain the white tomentum on their undersides.

The flower-heads (borne in early summer on stiff whitish stems which may be anything from 6ins. to 12ins. long) are hemispherical, and when fully open are 2ins. across, the rays being white and the disc florets yellow.

This plant, known in England for half a century, is far more hardy than it is credited to be, and where the better known Veronica Hulkeana thrives out of doors there also should this compositæ flourish. For it is the hardier of the two. Both grow together up to a height of 3,000ft. above sea level in the South Island; while this olearia is still at home at considerably higher elevation, growing on poor dry banks, which fact may

A DAISY BUSH OF STRIKING APPEARANCE, O. INSIGNIS.

point to the nature of the hospitality it needs in this country; but the site should be sheltered.

Good drainage is most essential to this plant, which is reported hardy in many places inland, even the Midlands.

Recently the botanists have removed it into a new genus, and their decree is that henceforth it shall be known under the name of "Pachystegia insignis." Nevertheless, no matter its name, it is a plant of easy culture, and, to quote from Cheeseman's "Manual of New Zealand Flora," "a very remarkable and handsome plant, quite unlike any other."

Olearia semi-dentata, of more recent introduction, is a much taller bush. A native of the Chatham Islands, this has lanceolate toothed leaves with grey undersides, 2ins. to 3ins. long and about ¼in. wide.

In early summer it bears in profusion beautiful mauve-rayed, purple-centred daisies 2ins. across on long, slender arching stems, and continues to flower spasmodically throughout the summer.

An additional feature of this shrub is that the flower is slightly fragrant, which fragrance two out of three people will resemble to "scented soap."

Olearia chathamica, introduced about twenty years ago, is possibly the handsomest. In leaf and flower it bears resemblance to O. semi-dentata, but it is altogether a more audacious plant. Its leathery dentated leaves (almost white on the undersides) are about 5ins. long and 2ins. wide; while its flowers, almost 3ins. across, with purple discs and rays paling with expansion to white, are, in June and early July, things of exquisite beauty.

The two last-mentioned olearias are essentially plants for mild seaboard districts, and the three now figure in more than one catalogue of choice shrubs. All the daisy bushes are of great value for garden decoration. They are beautiful in habit and bear a profusion of bloom. The hardy Olearia Haastii, which smothers itself with clouds of white blossom, and the ornamental O. macrodonta, are known to most gardeners, and are extensively grown; but it is the more uncommon daisy bushes, particularly the three that are described here, which deserve to be more widely cultivated, and there must be many gardens in the British Isles where conditions are favourable for them to succeed. W. R. J., *Anglesey*.

THE BUSY MAN'S PAGE

The Garden in September.

Work to be Done Now.

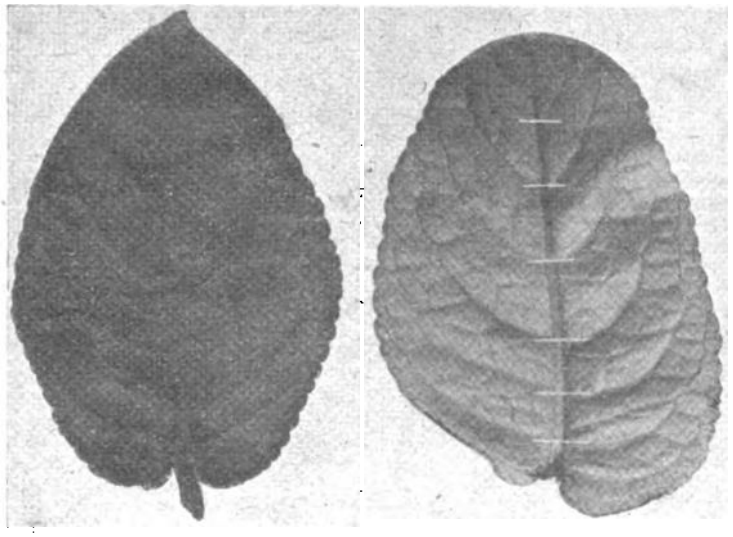
DURING September clear up, regularly, falling leaves from off lawns and flower beds. Tie dahlias and cut away all the side shoots. Later on in the month put out bulbs for spring display, hyacinths and narcissi being placed simultaneously in pots and glasses for window decoration. Earthing-up celery may be proceeded with, potatoes dug and arrangements for the winter and spring cropping of the vegetable ground carefully completed. Lift onions, drying them well in the sun, and gather tomatoes; transplant lettuces into frames for winter cutting, and thin spinach. Allow apples for keeping to hang as long as possible, and, after picking, lay them carefully away in a dry storing place. Borders may now be made ready for planting young trees, and strawberry beds for the forthcoming crop should be filled with healthy young plants. Damp must be avoided in the vinery where late grapes are ripening, and firing attended to. Cucumbers still bearing in the frames need air by day more than moisture now, and mildew is a danger to be overcome by caution in this respect and by the timely sprinkling of sulphur over the leaves. Before the greenhouse is filled for the winter is a good time for repainting, which should be quickly and efficiently done on dry days. The propagation of half hardy plants by cuttings should be completed, frames as well as the warmest spots in the underpart of the greenhouse or conservatory being fully utilised for the purpose. Watering in the greenhouse must be moderate, and ventilation free so long as frost is never allowed access to the houses.

Propagating Gloxinias by Leaves.

THE gloxinia, like many other beautiful plants with fleshy leaves, may be increased quite readily from leaf-cuttings. For many years the gloxinia was regarded by some as a subject that could only be well grown by those who possessed a stove-house; but such an erroneous idea has been exploded, and enthusiastic devotees of this plant find that it can be grown very successfully in just an ordinary greenhouse where a comfortable temperature can be maintained. The work of propagation by leaf-cuttings is usually done in the early autumn; the present period affords a most excellent opportunity for beginning this interesting work. This may be commenced as soon as the leaves are fully matured, and the older leaves are almost invariably selected for the purpose. Either pans or boxes should be utilised, as it is customary to deal with the whole leaf. Preference is usually given to the use of a compost of sandy peat and leaf-mould.

2.—THE LEAVES SPREAD ON A FLAT SOIL SURFACE AND HELD IN POSITION BY SMALL STONES PLACED ON TOP.

The whole leaf of the gloxinia is laid with the under side downwards, so that this rests on the surface soil. Before adjusting the leaf in position, incisions should be made at regular intervals along the mid-rib. The incisions should be made with a sharp knife, the mid-rib being cut through, or half through, at intervals of about 1in., more or less, either at the junction of each pair of ribs or alternately right along the whole leaf, as shown on the right leaf of Fig. 1. In consequence of this treatment of the leaf, little bulbs should form at each incision; in other words, a callus will evolve, and in due course tiny plants will develop, which, when well rooted, should be potted up individually into small pots. These little bulbs, or corms, will evolve before the leaf decays. The temperature in which the propagation of gloxinias by leaf-cuttings is carried out should be any figure between 60 degrees and 75 degrees. This is a wide margin, but it only goes to prove how very accommodating this subject is. No foliage will be developed on the little bulbs reared in this way; it is not until they are potted up in the spring, and grown on in the ordinary way, that they will be represented as young growing plants.



1.—GLOXINIA LEAVES SUITABLE FOR PROPAGATION.
The leaf on the right has been cut several times along the mid-rib. Roots form at these incisions.

Another method is that of cutting a gloxinia leaf in halves and inserting the leaf-stalk of the lower half in prepared soil in pots. Such pieces root readily enough if the pots are stood on a moist bottom on the bench of a warm greenhouse. Instead of pegging down the leaves, the same object may be achieved by placing two or three small pebbles thereon to keep them in position, as shown in Fig. 2. The soil should be made moist throughout in the first instance, and the surface of sand maintained in a moist condition by damping the ashes, etc., on which the pans and boxes should stand during the rooting process. Shade the leaves from the direct rays of the sun.

How to Treat Vacant Ground in the Kitchen Garden.

ROWS of peas, runner and dwarf beans and onions will be cleared off the ground during the early part of September. Now, it frequently happens that the surface of such soils is soon green with the seedlings of weeds which, if left, will grow rapidly and soon be beyond the Dutch hoe. Many kitchen gardens are neglected in this way during September and October, and some weeds are left untouched until spring, when they quickly flower and seed again, especially those of the groundsel. It is a great mistake to neglect this vacant ground. It could be profitably used in the following manner: When the summer crops are lifted, the weed seedlings are usually quite small, and the ground should then be hoed at once, and the majority of weeds are then totally destroyed in a very short time. Follow this hoeing immediately with raking, then the seedlings are destroyed quickly if the day is a sunny one.

There need not be any digging work or special preparation of the ground; simply clean the surface and sow, at once, and broadcast a few seeds of Green-top Six-weeks Turnip or a similar early variety. Sow the seeds thinly and rake them in well. Sow some French Breakfast and turnip-shaped radishes in the same way. Plant out endive and lettuce plants quite 9ins. apart, and they will come in very useful during the winter months. All The Year Round Lettuce or a similar hard variety should be selected. The soil is warm, and seeds in it germinate quickly; new roots form and grow rapidly on transplanted subjects. If, however, such catch crops are out of the question, the soil should be deeply dug or trenched forthwith and left in a rough condition throughout the winter. This course is much better than digging or trenching while the soil is sodden later on.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

After the Holidays.

IT is surprising how plants, when left alone for a couple of weeks, will run riot. A friend who has a small garden that is her great pride and care has just returned from a holiday in Switzerland, where she has been studying the alpine flowers. A few innocent, tall nasturtiums against a fence, acting on the principle that when the cat's away the mice will play, have literally overrun the tiny garden. To a lesser extent this is true of many plants this season. Owing to the continuous rain and warm weather, herbaceous plants also have produced an abundance of leaves, and in many cases only a few flowers. It does show how difficult it is to apply manure and fertilisers to the garden to avoid excessive foliage in a wet season.

Plants grown in poor soils naturally tend to make less foliage in a wet season than rich ones.

It would be worth while, at this late season, to go through the flower border and ruthlessly thin out overcrowded growths. Despite the paucity of blossom, a wet season is, on the whole, a good garden season. The Ministry of Agriculture's crop reports are encouraging to read, and from all parts of the country crops are reported to be good. Perhaps the amateur will be most concerned with keeping weeds down, owing to the difficulty, if not impossibility, of keeping the surface soil hoed. Giant weeds arise in two or three weeks, and these must be pulled out by hand. I am often asked if one should burn weeds of this character, and my advice is, unless they have already seeded themselves, to bury them in the part of the garden which is being dug, or to put them in the compost pit and scatter a little soil over them as well as a handful or two of lime to assist the decomposition. Weeds that are bearing seeds should, of course, be burnt; but if they are only in flower and no seed-pods are ripened, it can be safely assumed that, from the compost pit, no dissemination of the enemy will result.

SEPTEMBER IN THE TOWN GARDEN.

WHAT TO DO THIS MONTH.

1. *Lift and divide perennial plants that have finished flowering.*
2. *Clean up the garden. Rubbish and dying weeds quickly accumulate at this season.*
3. *Sow sweet peas intended for exhibition.*
4. *Plant all kinds of hardy spring flowering bulbs—hyacinths, narcissus, muscari, scillas, iris, snowdrops, crocus, chionodoxas, crown imperials, etc.*
5. *Plant tuberous-rooted anemones.*
6. *Plant winter aconites in bold patches at the edge of the shrubbery.*
7. *Lift tuberous-rooted begonias from the open ground, and commence to withhold water preparatory to drying them off for the winter.*
8. *Under the shade of trees plant hardy cyclamen.*
9. *Plant out cabbages on the vegetable plot. Allow 2ft. between plants.*
10. *Lift and store potatoes as they are ready. If any are attacked by blight be specially careful to sort them before storing.*
11. *Earth up celery.*
12. *Plant out cauliflower and endive.*
13. *Cut leaves from outdoor tomatoes to allow the sun to reach the fruits. Small green fruits can be used for pickling.*
14. *Keep the lawns well rolled and cut. Sow new lawns.*
15. *Renovate the rock garden. In towns it is usually necessary to rebuild this feature each three years.*
16. *Plant new strawberry beds.*
17. *Thin out canes of raspberries and loganberries.*

Raising Plants from Cuttings.

AS will be seen from the accompanying photograph, many town gardens grow plants that have to be kept through the winter, and a few hints on making cuttings will be helpful to most town gardeners.

For those who have no cold frame or greenhouse, early September is the best time for striking cuttings. In the garden there are many such plants, such as geraniums (zonal pelargoniums), fuchsias, salvias, heliotropes, etc., from which cuttings can be taken and rooted. Cuttings root more easily in warm weather, and while the commercial grower can use artificial heat, the amateur has to rely on the sun's warmth. Light sandy soil, with some leaf-mould intermixed, ordinary flower pots and a sharp knife are all that are required for preparing and planting cuttings. Choose sturdy side shoots, without flowers, about 4ins. or 5ins. long. Remove the two lower pairs of leaves and cut the stem below a joint, as roots develop best from the joints of a stem. The clematis and willow are two of the few exceptions to this rule. Place broken crocks in the bottom of the flower pots for drainage, and cover this with the flaky leaves and rougher bits of soil before filling the pots. Make holes for the cuttings (six in a 5in. pot) with a sharp pointed stick, and each hole should be just deep enough to take the cutting. You can easily tell if the cutting is touching the bottom of the hole, and if a space is left beneath it may result in "damping off," the common disease among unrooted cuttings. The pots can be stood out of doors and watered thoroughly, after which they should only be given water sparingly. Damp the foliage each evening, using a fine rose can, and shade from bright sunshine. Of course, if a cold frame is available, the pots can be put in this until the cuttings have rooted, but on no account coddle the plants, but give them plenty of air. The sturdier and hardier they are, the better will they be able to withstand the damp and frost of winter months.

AN ATTRACTIVE DISPLAY OF BEDDING PLANTS.
To raise a stock for next year, cuttings should be taken now.

How to Get Big Chrysanthemum Blooms.

EARLY sorts, like Horace Martin, still one of the best yellows, are in full bloom, but others that are only just showing their buds can be disbudded if you wish to have a few special blooms. Take hold of the shoot and carefully rub off all the side buds, leaving only the one at the top. This causes all the sap to go into the one flower, making the blossom larger than if all the buds were allowed to grow. One of the best of fertilisers is soot water. This makes the foliage a healthy green and gives added colour to the flowers. Owing to the weight of the flowers many varieties need the support of stakes. If left untied the shoots become twisted and untidy, and the flowers are spoiled by rain which splashes soil on to them. Those who grow these flowers in pots will need to water them more frequently now that the soil is full of roots. A top-dressing of rich soil increases the size and colour of the flowers.

THIS WEEK IN THE FLOWER GARDEN

A Decorative Lilac—Syringa Palibiniana.

DURING the last twenty years western and northern China have sent to us quite a number of highly decorative species of the genus syringa. Like other genera, as, for instance, berberis and cotoneaster, the lilacs show an astonishing development in this paradise of hardy ornamental garden plants. Among the true lilacs we have two distinct groups, S. villosa and S. vulgaris, of which each contains some very fine species.

Of the second group, S. vulgaris is the type. While S. villosa and its relatives flower from the terminal bud and develop their panicles just before the end of May, lasting until almost July, S. vulgaris, S. pubescens and S. oblata var. affinis often commence to flower rather early in April. Among the species related to S. pubescens there are some more from northern China of great garden merit on account of their hardiness and rich and ornamental blossoms. They are still very little known even in English gardens. I had the good fortune to study them in the Arnold Arboretum. One is S. Meyeri, a rather compact shrub with dense inflorescences of deep violet flowers. It had been detected by the late Dutch collector, Meyer, in a garden near Peking. According to a specimen collected by A. Bunge and preserved at the Museum at Paris, it seems to be wild in the north-eastern parts of China, where S. pubescens is at home. A second species forming a small shrub from north-western China is S. microphylla, a fine plant for a small garden. The last introduction from Korea is S. Palibiniana, of which I took this photograph in Mr. Lemoine's famous nursery at Nancy, France, at the end of May. It forms a slender, upright shrub of about 9ft. to 10ft. high. The leaves are densely pubescent on the mid-rib and the veins beneath. The panicles, the form of which is clearly shown in the picture, reach a length of about 7ins. There is an apparently even more ornamental variety, Kamibaysshii, which was also introduced in 1917 to the Arnold Arboretum.—C. S.

SYRINGA PALIBINIANA, AN ATTRACTIVE LILAC FROM CHINA.

Some Rockery Violas.

POPULAR as the pansy and garden viola have always been, it cannot be wondered at that the small-flowered violas are considered indispensable in the rock garden. Certain species might almost be called ubiquitous; and, in addition, there are rare little gems to gladden the heart of the connoisseur. Among the common kinds which merely require mention in passing are Viola gracilis, V. cornuta and the sweet violet, odorata. Speaking particularly of the first two, I would point out that named varieties are becoming plentiful and, in the main, are eminently desirable. Let me mention, in particular, the white Clarence Elliott, the black Black Knight, Perry's Yellow, Royal Blue, Purple Robe, blue Lady Crisp and Bambour, an improved type. As a variation to cornuta itself, we have the old alba, blue papilio and the deep purpurea; newer, perhaps, are Mauve Queen, G. Wermige (white) and a deep blue, Colorado. Coming to other species, I must enumerate lutea, a fine yellow, which also can be had as a soft purple, The King; Munbyana, an early-flowering violet-coloured kind; pedata, the "peat" violet—best, perhaps, in its variety bicolor, violet and blue; bosniaca has red magenta flowers; Fondrasi-lactea, smallest of all the violas, has white, dainty flowers; and, to close the list, I add adunca (purple), arenaria (rose red), glabella (yellow), palustris for wet places, and biflorus for shade.—LANARKSHIRE.

Plant the Madonna Lily Now.

THE present time is undoubtedly the best in which to plant the old Madonna lily, Lilium candidum. By this time the flower-stem has almost died down and the bulb is inactive. Before winter, the bulb will manage to make a basal tuft of leaves, and it is then certain to flower again next season. Planting at any other time means the sacrifice of a year's flowers. Plant this lily at least twice the depth of the bulb and place a handful of clean sand below and another above the bulb to prevent decay in a wet soil. Correct preliminary preparation of the soil is an additional guarantee of success. Dig the site deeply and enrich the soil by adding well rotted leaf-mould, rotted but not excessively rich manure or sifted mould from decayed rubbish; a soil rich in humus is best for them. Amateurs who cannot get either of these will find that hop manure or coarse bone-meal is the best substitute. A final word to those who must buy new bulbs—buy them as soon as you can get them and plant at once; also mix a dessertspoonful of sulphur with the sand used at planting time when the bulbs come from an unknown source, as a preventive against disease.—H. H. A.

How to Grow Nigella and Cornflowers from an Autumn Sowing.

THE nigella is a lovely flower, delicate in appearance but quite hardy, but it is stronger in both plant and flower from an autumn sowing than from a spring one. The present time is a suitable one for sowing the seeds, and the resultant plants will bloom early next June and continue to do so throughout that month and until the middle of July. In order to extend the flowering period cut down the plants to within 3ins. of the ground level directly the main flower stems are denuded of their flowers. In the course of a fortnight new shoots will be growing freely, and these should be assisted by weak doses of liquid manure applied twice weekly and very frequent applications of clear water during dry weather. The second crop of flowers will be available throughout August and the first half of September. From two spring sowings flowers will be plentiful from early in June until the end of September without a break. These remarks apply, also, to the cornflowers.

The situation must be an open one, as drawn-up young plants will not be satisfactory. The soil for the nigella should be rather richer than that for the cornflowers. In medium good loam the nigella plants attain a height of 18ins.; in poorer soil the cornflower plants grow 4ft. high. Each individual nigella plant will measure, approximately, 18ins. across, and each cornflower 3ft. across. The quantity of bloom that the plants bear is really wonderful. Sow the seeds in shallow drills in very clean ground, and duly cover lightly with fine soil. The drills for the nigella being 2ft. apart, and those for the cornflowers 4ft., leaves ample room for the resultant plants to attain to their maximum size. Thin out the young seedlings in both cases to a distance of 16ins. at least in the drills; then the plants will meet and overlap but yield a great quantity of high-class bloom.—HANTS.

Chrysanthemums and Dahlias.

Feeding and Staking.

BOTH dahlias and chrysanthemums have grown rapidly during the past few weeks. The first named, possessing rather heavy foliage, suffers severely from strong winds if they are not well supported by stakes. Where they are grown in new shrubberies a few branching sticks will afford the necessary support as the shrubs act as a screen to a great extent. In the more open quarters stronger stakes will be necessary to supplement those fixed earlier in the season. If ordinary care be taken, all, or nearly all, the stakes may be hidden from view by the foliage, and at the same time afford the necessary support. In the case of chrysanthemums growing in herbaceous borders, the branching sticks will support the plants sufficiently and in such a way as to retain the natural bushy form of each. The sticks should be fixed firmly in the ground near the outside portion of each specimen. Those plants, grown in the open ground now and intended for the supply of cut blooms when the plants are lifted and re-planted under glass later in the month, need only one stake to each.

Digitized by Google

This stake should be inserted firmly in the soil on the south-west side of the plant and a strong piece of soft raffia fixed to it and then passed round the main branches, entirely enclosing them at about two-thirds of their height. With regard to the feeding of both kinds of plants discretion must be used, for indiscriminate feeding would do more harm than good in some cases.

Where judicious feeding will be beneficial, use weak doses of liquid manure and cool artificials where liquid manure cannot be obtained. If the plants are growing in a rich soil, do not feed at all; but where they are planted in a poor one, feeding twice a week will greatly strengthen them and also the flower stems.—G. G.

A Beautiful Rock Rose.

(*Cistus Loreti.*)

AMONG the dwarfer rock roses there is none more charming than Cistus Loreti, also known as C. lusitanicus. This is a hybrid between the true gum cistus (C. ladaniferus) and C. monspeliensis. It makes rather a spreading bush, not often above 3ft. high. The foliage is an attractive fresh green which affords a delightful setting for the flowers. These latter, which are nearly 3ins. across, are singularly beautiful, the pure white petals each having a blotch of vivid carmine-crimson at its base, while the prominent wreath of stamens is golden yellow. C. Loreti excels also in a natural elegance of growth. It is one of the hardiest of its race and, unlike most others, its flowers are retained until evening, or, in dull weather, even to the following day. C. Loreti is a most prolific bloomer, and all it asks is a root-run in the poorest of dry, stony soil (with or without lime) and full sun. Propagation is carried out by means of cuttings. Any unflowered shoot of half-ripened wood about 4ins. long will readily strike if potted in sandy soil during the later summer and placed in a closed frame. Such cuttings will often commence flowering the following year, but it is usually wisest to pinch them back once to encourage a more bushy growth.—J.

A FREE-FLOWERING ROCK ROSE, C. LORETI.
It makes an admirable plant for clothing a dry wall.

A Good White Oxalis.

IT is not often that an albino variety excels in vigour and prolificacy over the typical plant, but the white form of the beautiful Oxalis floribunda is an exception. This is one of the best of its race in its own colour where a rock plant is wanted that will bloom continuously and abundantly from spring to autumn. In my garden, at any rate, this cheerful little plant comes into flower before O. floribunda itself has opened an eye, and it is full of flower for months after the latter has gone over. Moreover, O. f. alba is willing to grow and do well in the poorest of soil.

THE DECORATIVE WHITE FORM OF OXALIS FLORIBUNDA.

I have it in shade and sun and in the drip of trees, and it is invariably bright and happy. While it is easily propagated by breaking up the knobbly roots during autumn or winter, it never spreads of itself or becomes in any way a nuisance. In the rock garden, or front of the border, it can be placed with one's choicest plants without fear of undue trespass. It does not grow quite so large as the best forms of the type, my plants averaging about 8ins. in height and covering a space 1ft. across at the most.—A. T. J.

The Cleft Gentian.

A Decorative Late-flowering Species.

SOMETIMES known as the crested gentian, G. septemfida is at once one of the most beautiful and easily grown of its race. Indeed, it is so amenable to cultivation that half a dozen plants (some of which come into my photograph) put into ordinary light kitchen garden soil

AN ATTRACTIVE LATE FLOWERING GENTIAN, G. SEPTEMFIDA.
It is well adapted for the rockery or for edging a path.

have prospered abundantly for several years. Moreover, they have always afforded an unusually long blooming season, the first flowers appearing early in July and the last not being over until the end of September. The colour of the large bell-shaped beautifully fringed blossoms is a particularly good, clean blue, and the habit of the plant all that could be desired. G. septemfida is especially useful in the rock garden, since it is at its best during a period when there is comparatively little colour, and among gentians it bridges the space between the earlier ones and the ornate and willow gentians which follow it. It is, of course, a true alpine and perfectly hardy. The plants referred to never get any attention beyond a cutting back when flowering is over, but under drier conditions they are the better for a good top-dressing of leaf-mould, sand and loam in spring. There are several varieties of this gentian. Lagodechiana is a rather smaller but very attractive form, and G. s. cordifolia and G. s. latifolia are distinct and good. Division in autumn or spring is the best means of propagation, but the cleft gentian may also be raised from seed.—A. T.

A Strong-Growing Border Perennial.

(*Inula glandulosa.*)

A VERY useful plant for the herbaceous border or for the semi-wild garden is Inula glandulosa. This plant, which is a native of the Caucasus, produces solitary flower heads of a very fine shade of yellow. As a rule the height of the species is about 2ft., but in good soil this is much exceeded. The flowering time is in the late summer, when a fine specimen of I. glandulosa is really very effective. The plant is easily increased by root division either in the spring or autumn.—L. B.

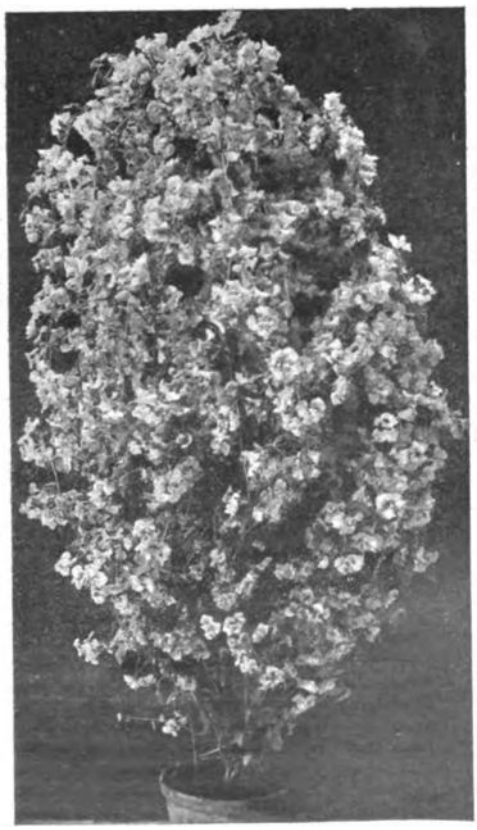
SEED SOWING & BULB PLANTING IN THE GREENHOUSE

Nemesias and Clarkias in Pots for Early Flowering.

THESE two kinds of flowering plants are remarkable for the freedom with which they flower and for their long period of flowering. The nemesia is half-hardy and must be grown under glass during the winter and spring, and the clarkia is quite hardy and may be grown in a cold frame; but as the object of this note is to show how the plants may be had in bloom early in the year, they must be grown in pots and afforded greenhouse treatment.

Old soil in which there may be fungus should not be used. Do not use old potting soils nor soils from old boxes, nor any from heaps that have remained for a long time under trees. Rather use new sweet loam and half-rotted leaf-soil with old mortar rubble. The seeds should be sown from now on until mid-September. Select 3½in. pots, place one hollow crock in each pot, then a tuft of fibrous loam to secure good drainage. Three parts fill the pots with the compost, press and level it; then water through a fine-rosed watering-can. One hour later, sow the seeds in a circle a little more than half an inch from the sides of the pots. Sow the clarkia seeds thinly and those of the nemesia rather thickly, as they do not germinate as freely. Cover with fine soil, but do not water the covering soil. In due course the seedlings will appear and they must be grown on very hardily, subjected to plenty of air and thinned out, the clarkias to three and the nemesias to four or five in each pot. The object of the cultivator should be to obtain strong root action. If the pots are well filled with roots by December, the plants will make splendid progress in January, February and March, after being, early in the year, transferred to 6in. pots. Clarkias may be grown 18ins. across and nearly 4ft. high, well clothed two-thirds the length of their stems with flowers. At the final potting use a small quantity of bone meal in the potting soil and be very careful not to apply any strong manures in liquid form afterwards. There are now many brilliant colours, but Salmon Queen, White Queen, Orange Queen and Ruby King will be sufficient. If some plants are grown in boxes 6ins. deep, the spikes of flowers will be charming used in a cut state in vases for decorative purposes.



CLARKIA IS ONE OF THE MOST DECORATIVE AND EASILY GROWN ANNUALS FOR THE COOL GREENHOUSE.

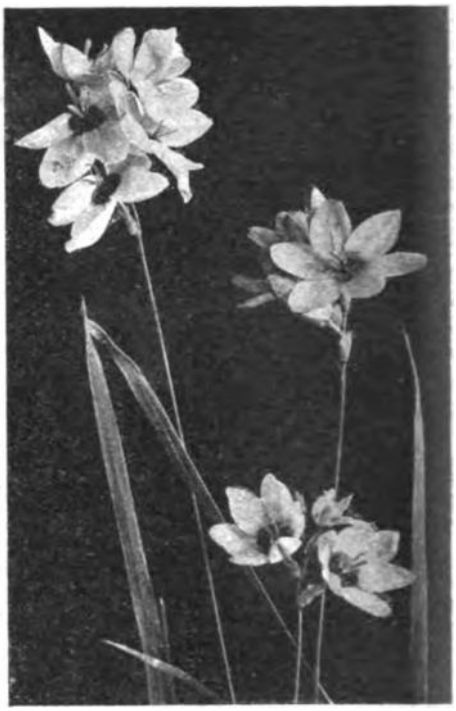
Ixias: Dainty Bulbs for the Cool Greenhouse.

THE arrival of a bulb catalogue to-day reminds me that I must order a fresh supply of these pretty, half-hardy South African lilies, both for the cool house and for outside planting. The bulbs are potted up in succession from now onwards until December, rather firmly, and in a compost not definitely enriched with manure but containing good-hearted loam as a basis. Six or more bulbs fill a 5in. pot, and they may be completely covered with sifted compost to a depth of 1in. Plunge the pots to the rim in ashes outside, or stand them in a cold frame, the treatment being much the same as that given to freesias. Water very sparingly at first; but, as growth advances, give more and expose fully to light and air. Later on, when taken inside the greenhouse, stand them on a shelf near the glass. After flowering, dry off gradually to plump up the bulbs for another year. The flowers are borne in clusters on stiff wiry stems; they open widely and look very pretty, and in a cool house last long. In the open, ixias succeed in a sheltered, sunny corner where the soil is well drained. Plant 3ins. deep in clumps and cover the soil with some kind of protective mulch. The old varieties, Galatea, Snowflake, Excelsior, Village Maid, Golden Eye, Bridesmaid and Vulcan, are first-class, while a mixture produces flowers of rich and vivid colouring.—A.

Raising Fine Cyclamen from Seed.

THIS is the only satisfactory way of raising new batches of these plants. The corms may be divided when new growths are about 1in. long, but it is not a method that one can advise. The corm is solid and only an expert cultivator can deal with it in this way. Seeds may be sown in September or in February, and it is not difficult to raise good batches of seedlings from seeds sown at either of these dates. The most suitable compost is one of light turfy loam, a little sandy peat and a small proportion of half-rotted leaf-soil. Pans or pots are better than boxes for sowing the seeds in. Provide very sound drainage, cover the latter with half-rotted leaves, then place in the compost, firm and water it. One hour or so afterwards sow the seeds 1in. apart and cover them nearly half an inch deep with the finer part of the compost.

Place the pan on a stage in a cool part of the greenhouse or in a cold frame, and cover with glass and paper. Do not water on the surface, but three parts immerse the pans in a vessel of water when the latter is needed. The seeds may not germinate regularly, but as the resultant seedlings are free of each other, the more forward ones can be transplanted in pots or pans at 2ins. apart quite near to the edge, then they will winter well on a greenhouse shelf if the structure is heated a little. This method means express culture of these plants and is superior to the old one of sowing thinly and allowing the resultant seedlings to remain undisturbed in the seed vessel for a year. The soil becomes sour and many young roots perish in it. The young plants should be potted singly directly new leaves and roots begin to grow in the spring.



GRACEFUL FLOWER SPIKES OF THE AFRICAN CORN LILY (IXIA).

Stocks for the Greenhouse.

Make Sowings at the Present Time.

FEW plants are more easy to manage and better worth growing in the greenhouse than the East Lothian, intermediate and Brompton Stocks. These naturally flower in the winter and early spring, and in some localities do quite well out of doors. With protection, much better results are secured, and the modern varieties with their wonderful range of colours are worthy of special cultural care. Excellent results are secured by growing the plants in an unheated greenhouse or frame and, as a matter of fact, the sturdy specimens produced without artificial heat often flower more freely than those which are coddled. The best time to sow the seed is now. Sow in boxes or pans of fine soil and place these in a frame. Thin sowing is important and, if by any chance the seedlings do come up thickly, remove a proportion of them to prevent overcrowding. When the plants are big enough to handle easily place them in small pots and then move on as required. In the end it is a good plan to have two, or possibly three, plants in a 6in. pot. Light soil may be used up to the last potting, and here it is well to employ something a little more substantial. The double varieties are the most decorative and, as a rule, the single-flowered specimens (of which there is sure to be a certain number) may be discarded or placed in some odd corner of the garden in the open. The double forms show an altogether more stocky development. During the dark days of winter water should be given sparingly and, except in very bitter weather, the ventilation should be as free as possible.—S. L. B.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

THE official report of the Scottish Sweet Pea Trials in 1927, which has been compiled by Mr. John Smellie, makes instructive reading. A total of eighty-eight varieties were received from eighteen raisers, of whom Messrs. Robert Bolton and Sons were the chief contributors, their efforts in the production of new sorts being represented by sixteen varieties. Mr. J. Stevenson, Wimborne, and Messrs. C. Morse and Co., California, came next in order with fourteen and thirteen entries respectively. The information contained in the detailed record testifies to the difficulty experienced by trade growers in their endeavour to produce true stocks. No fewer than twenty-seven varieties were unfixed, a number which works out approximately at 30 per cent.; and as showing the degree of impurity distinction is made between mixed lots and those containing rogues. As the latter vary in number from one to three, it is obvious that the mixtures exceeded the latter figure. The seedlings sent by seven firms are certified as pure, but their contributions were proportionately small and in no case did the varieties exceed five in number. There was a time, and that not so long ago, when American seed obtained a bad reputation in this country because a number of the stocks were unreliable in respect of fixity; but the Helensburgh trials prove that the leading American firms are no worse than the English raisers in that respect, and, compared with certain home growers, they occupy a more favourable position. Messrs. Burpees' trio are all true; while Mr. Damerun's three are all lacking in purity; and of Dr. Hinton's little lot only one variety came true. Then, if a similar test is applied to the larger individual collections, the results favour Messrs. Morse, who are credited with eleven true and two unfixed seedlings, which compares with Messrs. Bolton's group of eleven fixed and five unfixed introductions, and Mr. Stevenson's record of eleven fixed and three unfixed sorts. Messrs. King and Co.'s position was worse than either of these English firms, for only three of their eight varieties are declared to be true: all of which goes to prove that the sporting character of sweet peas is an ever present source of worry and disappointment to breeders of our popular annual.

Scottish exhibitors were well represented at the Southport Show and are to be congratulated on the measure of their success as reflected in the prize list. Competition was exceptionally keen in the pansy and viola classes, and, while the northern contingent excelled in those classes which recognised the Scottish system of showing the flowers on boards, they have much to learn in the art of staging the blooms in vases, a practice of long standing at English shows and one that has recently been introduced at the more important exhibitions in Scotland. The entries in a number of classes exceeded twenty, and in proportion to their numbers the Scots did remarkably well. It was expected that the first prize for twelve bunches of grapes in four varieties would go to Glamis Castle, and when it became known that Mr. Donald McInnes had been defeated by a very few points there was a general feeling of disappointment among his countrymen. Mr. David Airdrie, Dunlop House, had also to be content with second place in the class for four bunches of grapes; and, singular to relate, Mr. S. Gordon, Monreith Gardens, was assigned a similar position by the judges in the other three grape classes; while Mr. McInnes added two additional second prizes to his list of honours. And what is to be said of Mr. Grigor's triumph in the sweet pea section? Located as I was in the secretary's tent, it became an almost monotonous repetition as each successive sheet was received from the judges. Twelve first prizes gained in the single vase section practically exhausted all the colour classes, and as the northern grower also excelled against fourteen opponents in the trophy contest for twelve vases one welcomed his defeat in the Eckford and Bolton competitions, on the principle that the honours should go round. It was a remarkable record, and an inspection of the well grown blooms suggested that Banff had been favoured with better weather than had been experienced in other parts of Scotland, an inference that was confirmed by the fact that Messrs. Dobbie and Co. had to give up the idea of showing flowers and confine their exhibit to a collection of potatoes which, in its own way, was an object lesson in the cultivation of clean tubers of uniform size and quality. Messrs. Smith and Son, Stranraer, represented the Scottish rose nurseries in the prize list; an amateur, in the person of Mr. D. Whitelaw, Station House, Lawrencekirk, was responsible for the best six vases of gladioli; and the first prize collection of twenty-four living British wild flowers staged by Mr. Robert Hogg, Greystone Cottage, Castle Douglas, was a most creditable effort. The Glasgow and West of Scotland Horticultural Society sent a deputation, consisting of Messrs. Charles Young (Kinnishead), Joseph Dobson (Glasgow), David Torrance (Busby) and John Smellie (Helensburgh), the latter of whom also officiated as a judge.

August will be long remembered in Scotland for its unseasonable weather. The rainfall was abnormal, cloud-bursts and thunderstorms were common, and during the few brief dry spells several degrees of frost were registered in different parts of the country. Occasionally the wind was high, especially on the west coast, and snow was the only kind of weather that was not sampled. Such extreme conditions have had an injurious effect on garden bloom, which is usually at its best in August, and this, again, is reflected in the decreased entries and inferior quality of the exhibits at the various flower shows. The trade has also been badly hit, and as a consequence the firms have cancelled space booked at various exhibitions. ST. MUNGO.

Flower Show Fixtures.

September 10th.—Barrhead, Springburn and Cowlairs Chrysanthemum; Haddington, Kilbarchan, Moffat.

September 14th-15th.—Royal Caledonian, Edinburgh.

September 16th-17th.—Springburn Northwestern.

September 17th.—Hutchisontoun Chrysanthemum.

September 24th.—Renfrew Plotholders, Walkerburn, Caledonia (Glasgow) Chrysanthemum.

WHAT OUR READERS SAY

A NEW HYBRID FRUIT.

SIR,—This is a corner of my new hybrid fruit plantation. We call the fruit "Jamberry," because one can make the most delicious jam from it, by merely adding a correct proportion of sugar to the fresh picked berries, no cooking whatever being required to preserve it. Its flower is large and white, something like a clematis.—MISS J. R. MCCORMICK, *Williamstown, Kells, Co. Meath.*

A PLANTATION OF THE "JAMBERRY"
This fruit requires no cooking to preserve it.

MY IRIS GARDEN.

SIR,—These notes on a small iris garden may be of interest to some of your readers. I am planting the irises at the present time, and as the season is such a wet one I can go straight ahead with the work and the roots will have time to go down into the earth and get a good grip of it before the winter comes. The main part of my iris garden is a long border facing due south, with a thick hedge of laurels and flowering shrubs to ward off the north wind, and, what is more necessary, a 6ft. grey stone wall to break the west wind which sweeps across the country from the Bristol Channel in devastating strength.

Some little distance from the shrubs I have an irregular hedge of tall and dwarf lavender, and among it in groups of the tall-growing Pallida dalmatica, whose opalescent, sword-like leaves look so beautiful among the lavender. I have three sorts of pallida—Princess Beatrice, Albert Victor and Mist, the latter being extraordinarily vigorous. I bought a couple of plants of it eighteen months ago, and it was a glory in the garden for two

Digitized by Google

months this last spring and has spread into huge clumps.

Many of the new irises are most beautiful, but I am keeping mostly to old and tried friends which I am gathering together from various parts of my very mixed garden. There is a big clump of the golden-banded I. Ochroleuca in the coolest corner under the old grey wall, which has been there some time now and gives us many beautiful flowers in the early summer. Then, there are clumps of my much-loved (true) Fleur-de-Lis with its lovely pearl-tinted flowers, and Flavescens with its soft yellow blooms; and Mrs. H. Darwin, where you can cut and come again; and Thorbecke and Elizabeth and Canarie, another very floriferous iris; and Queen of May, such a lovely pinky lilac flower; and gracchus and Isolene, Mme. Chereau and Madonna—but the latter has not yet flowered, for I think I planted it too deeply, as I used to do many of my irises.

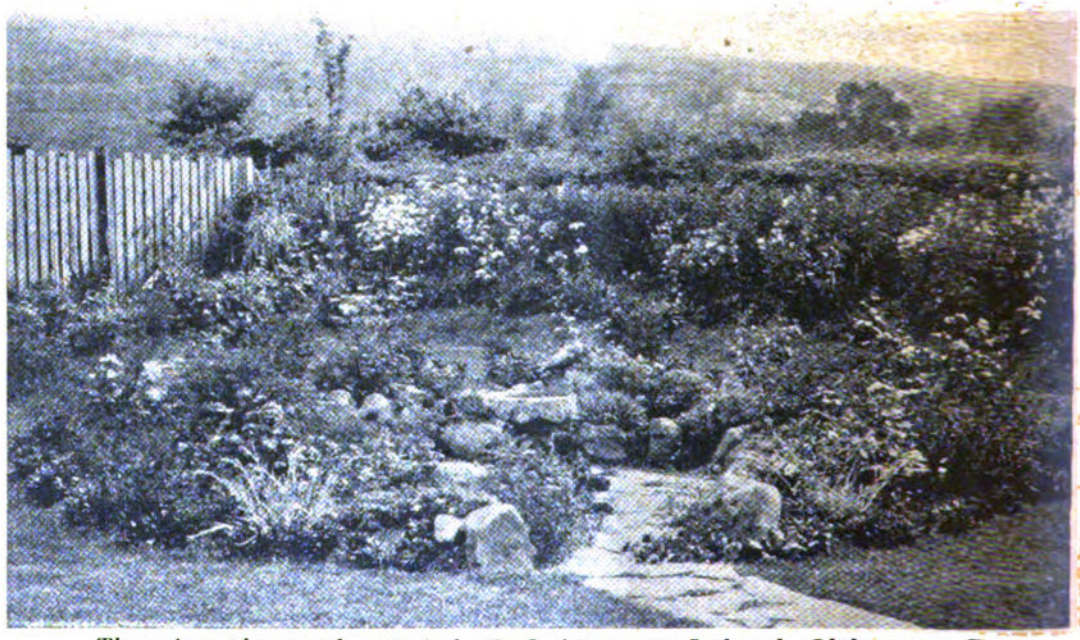
Rather alone, for she brooks no rival, is Longipetala, most exquisite of blooms. Princess of Wales is a grand white iris. Kharput I have just put in and shall plant dwarf thyme and rosemary and early crocus about her feet, to remind her of her home in sunnier climes than this; and only so late as yesterday I planted sambucina, the plum-scented iris, and she came to me with some of her seed-pods on, and I shall sow some of the seed if I can ripen it. I am not quite clear as to sambucina being plum-scented, as described in the catalogue issued by the firm I got her from, for I am told that graminea has the scent of ripe greengages However, we shall see.

Then, I have sibirica orientalis and Perry's Blue, a lovely thing, and Snow Queen, and, running in and out towards the front of the border, I have the dwarf pumila and chamæiris hybrids Cyanea (which is in flower at the present moment, August 16th), also lutescens and Aphylla Ditton Purple, with Snowcap and atropurpurea and other unnamed pumilas. This ends the list of the present occupants of my iris patch, but I hope to go on collecting—I like to feel that there are always more to come. As Robert Louis Stevenson aptly remarks, "It is better to travel hopefully than to arrive." — M. W. BOTHAMLEY, *Yatton, Somerset.*

OUR PHOTOGRAPHIC COMPETITION

The announcement made last week that our Photographic Competition would close with next week's issue and that readers should use their cameras during the finer days that promised, has produced a large number of photographs. It may not be out of place to repeat that fellow readers will benefit in due course when, from time to time, we publish examples of the delightful and constructive pictures which have been received and will continue to be received if opportunities are seized during the remainder of the gardeners' harvest time.

This small sunk rock garden my wife and I made in March last. The paved inner circle—which is approached by two shallow stone steps—is bordered by a rockery of Dartmoor stone and is surrounded by an outer bed planted with choice roses, carnations, mignonette, etc. In the rock garden we have had a succession of plants in bloom since early spring, such as several varieties of saxifrage, alpine phlox, veronicas, linaria, arenaria, etc., and now the red linum makes a blaze of colour, as also does the beautiful orange mimulus. The bird bath in the centre is an attractive feature, and the varied colour of the crazy paving, which is of local stone, gives a warm and pleasing effect to the whole scheme.

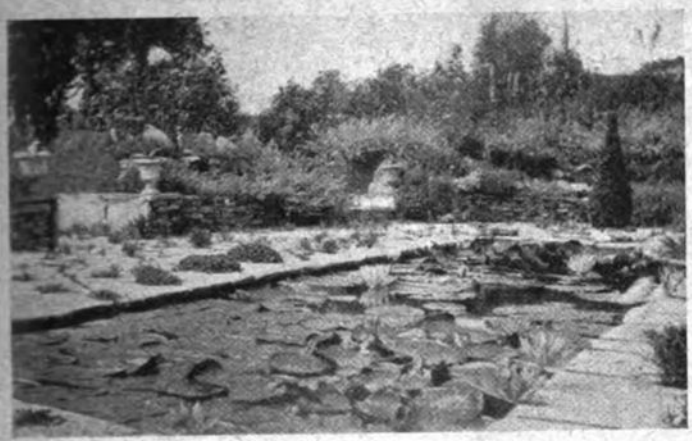


The guinea photograph, sent in by G. J. ATKINSON, *Inglenook, Okehampton, Devon.*

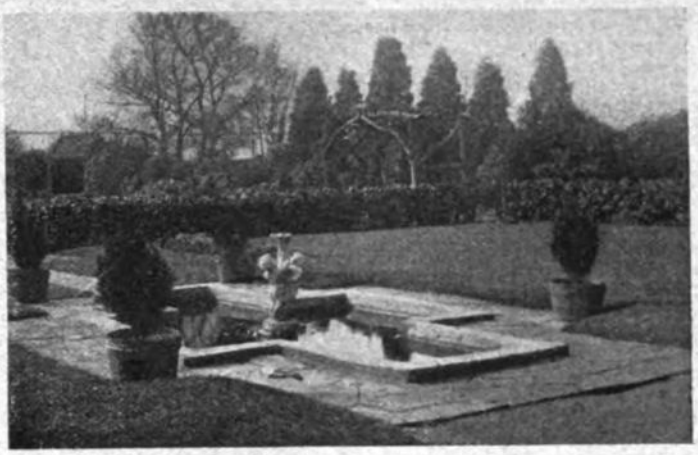
In the foreground of my border on the left are flowers of mauve and violet colour, including viola (Juliet), viscaria, Campanula (carpatica), Campanula (persicifolia, Telham Beauty), scabious, agapanthus, platicodon, veronicas backed by delphiniums; then come scarlets and crimsons, verbena, phlox, antirrhinums, backed by gladioli and dahlias, galtonias merging into pinks, including phloxes, pentstemons, linums, polygonums (Affine), Shirley poppies and sidalcias. On right are yellows, then orange, orange scarlet, scarlet Shirley poppies and montbretia; then yellows again, anthemis (in variety), heleniums, violas, achillea (eupatorium), œnothera (missouriensis), genista (tinctoria), sedums; then whites, and lavenders at intervals throughout the border. J. FRANK WHITE, *Redlands, Longstanton, Cambridgeshire.*

Award of 5s.

Digitized by Google



I took this photograph of my lily pool and rock garden last July. Only eighteen months ago it was just an ordinary flat lawn, but now it is the most delightful part of the garden. Between the crazy paving stones and in the crevices of rock work numerous rock plants are growing, such as saxifrages, rock roses and dianthus, and in the background are brooms, azaleas and other flowering shrubs. J. B. NEWMAN, *Lansdown House, Harlington, Middx.* Award of 5s.



This small formal lily pool, which I constructed entirely by myself, has greatly added to the charm of my garden. The pool is made of concrete and has a cement lining. The water is supplied by the town water supply, and the overflow drains away into a sump pit. The water-lilies are now doing well, and the four plants of Cupressus Lawsoniana erecta viridis in the tubs are extremely ornamental. P. BLUNDELL, *The Grange, Leagrave, Luton.* Award of 5s.

This part of my garden is quite secluded. Crazy paving surrounds the old sundial, and in the cracks between the stone I have sown love-in-a-mist and poppies. J. B. KING, *Foxley Lane, Purley.* Award of 5s.

The raised beds on either side of this winding, paved path give a pleasing effect. An arrangement of this kind seems particularly useful where the space is limited, and in avoiding straight lines a larger variety of planting schemes can be adopted, while the flowers have a much prettier setting. H. G. SHORT, *Oxgate Gardens, Cricklewood, N.W.2.* Award of 5s.

This photograph shows part of what was once an unsatisfactory herbaceous border. Nothing grew well, as part of the border is very dry and sunny and part is very damp and sunless. We took it up bit by bit, and by introducing large stones and making different levels it is now a most satisfactory addition to the rock garden. MISS A. CAMERON, *Duns, Berwickshire.* Award of 5s.

NOTES ON FRUIT AND VEGETABLES

Staging Vegetable Exhibits.

HAS it ever struck you what a difference is made to a vegetable exhibit by the way in which it is staged? A judge is, of course, expected to examine each exhibit and judge it according to the quality of the produce; but he would be scarcely human if he were not to some extent influenced by the superficial impression which he receives first. It is extraordinary, too, how easily the novice is led into the fatal error of disobeying rules, how he confuses "kinds" and "varieties," adds trimmings where these are forbidden, or puts seven where six fruits or flower spikes are demanded. Vegetables do not need any adornment. Onions should be neatly cut off, turned over and tied; the root crops clean, trimmed of surplus leaves, and not too coarse; the beet of even size; cauliflowers trimmed of only the toughest of the outside leaves, and the cabbages, though large, should not be overgrown and coarse.

I have known amateurs take their vegetables to shows just as they came from the allotment or garden. Think what this means. In the first place, the roots cannot be properly cleaned without scrubbing. To try to do this at the show itself is to make yourself a nuisance to your fellow-exhibitors, and to the stewards. As far as possible, the exhibit should be ready to place on the allotted space before you start for the show tent. If outer leaves, stems and other odd trimmings are removed at the last moment, it should be the care of each exhibitor to see that his rubbish is cleared from the show room or tent, and not left for others to remove. In small flower shows such small points as these mean a great deal to the organisers. Flower shows are essentially co-operative affairs, and I would plead with all intending exhibitors to help and not hinder those who are in charge.—R. S.

Gathering and Storing Potatoes.

THE in-gathering of the potato crops usually extends over a wide period, beginning with the first earlies, which this year are proving more or less disappointing on account of the dry spell. Fortunately, the later planted varieties seem more promising.

The first consideration is the selection of seed from the varieties to be planted next year, the best results being naturally got from well developed and fully matured plants. Use, if possible, a five-pronged fork, care being taken not to insert it too near the stalk, otherwise many tubers get pierced. The fork should be passed through the soil again in order to bring any stray tubers to the surface. If the weather is favourable they are benefited by being left on the surface for a day and turned over, but not exposed long enough to start greening. At the same time, a diligent watch should be made for any diseased tubers; such should be consigned to the fire with the haulm. Sorting is best done as each plant is dug out. The seed potatoes may be left on the surface for several days in order to get thoroughly greened, as they not only keep better through the winter, but become distasteful to animal raiders. The small potatoes, which are generally cooked and given to pigs and fowls, should all be removed, otherwise they will give trouble the following year.

There are different methods of storing potatoes according to circumstances, the most convenient being a cellar or building where they can be protected from frost and light. Many people place them in heaps or clamps in a convenient spot in or near the garden, covering them with straw and a good spit of soil, care being taken to leave a vent at the top for the escape of heat. On the approach of severe frost extra covering should be added. When the weather warms up on the approach of spring, sprouting begins, to retard which it is a good plan to let in more air by removing some of the earth from the top.—G. S. T.

Established Strawberry Beds.

THESE should be put in order as soon as the layers for making fresh plantations have been removed. The old, useless leaves should be cut off, as, if left, they may be a source of danger by spreading disease—strawberry mildew, for instance, the spores of which they frequently harbour. Care, however, must be taken not to damage the young leaves in the centres of the plants, as every healthy, fresh-looking leaf adds to the strength of the crowns, and this enhances the prospect of a good crop of fruit the following season. All runners should be removed, and, with this object in view, the bed should be inspected frequently during the remainder of the growing season. All rubbish—leaves, runners, mulching material and weeds—is best disposed of by being burnt, and the residue scattered around the plants near the crowns will be made good use of. Healthy plants which are backward in growth will benefit from a sprinkling of a good, quick-acting fertiliser; debilitated specimens are not worth consideration. To complete the work, break up the surface soil with a draw hoe, or lightly prick it over with the fork, but during the process the greatest care must be taken not to damage the feeding roots. A careless worker, by cutting deeply into the soil, may easily do more harm than good. Surface cultivation may be continued, to accelerate growth and promote cleanliness, whenever the ground is in fit condition to work on and the need for such attention is apparent.—J. C.

Treatment of Greenhouse Peaches After Fruiting.

WHEN all the fruits have been gathered from peach trees under glass, the earliest opportunity should be taken to do what is necessary to facilitate the ripening of the new wood, for on this largely depends the success of next year's crop. Every shoot retained should be fully exposed to sun and air, and though, where the trees have been properly cared for, there will not be much superfluous growth to cut out, a final inspection at this time will be almost sure to reveal the presence of some shoots of the current season for which sufficient space is not available. The old bearing wood should be removed generally; it should be retained only to the extent of preserving any desirable young growths supported by it. Admit plenty of air by night and day, both doors and ventilators being left open, and keep the border moist. Perhaps the latter point needs emphasising, as every spring there are many anxious enquiries concerning the cause of the fruit buds dropping just as growth is recommencing. Without sufficient moisture at the roots after the fruit has been gathered, the leaves drop prematurely, and the development of the buds is thereby arrested, the result being apparent by bud-dropping when the sap begins to rise. Plump, well matured buds produce strong blossoms, and by watering the borders when necessary and regularly syringing the leaves to keep them healthy till they drop naturally, the desired end is most likely to be achieved. A dressing of a suitable artificial fertiliser will be beneficial to established trees whose growth is below normal.—C.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful and interesting hint sent in by a reader. Five shillings will be paid for all others published. Payments for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF-GUINEA HINT

Propagating Lemon-Scented Verbena.

Many people find this difficult to strike from cuttings. It can easily be done in spring, the main object being to keep the cuttings from flagging. Another way which, perhaps, is easier for the amateur, is by layering in early autumn. Select half-ripened shoots, make a tongue by cutting through a joint in the same way as you would a carnation, using some leaf soil and sand to keep the tongue open. Lift in spring when growth commences.—F. D.

Sending Flowers by Post.

At this time of year many gardeners will be thinking of sending boxes of flowers to their friends. Here are a few simple rules to ensure them arriving in good condition and lasting as long as possible. First and foremost, never send flowers directly they are picked. Always put them in water for several hours first. Pick in the early morning or the cool of the evening. Don't pick during or immediately after heavy rain. Choose a box that will only just hold them and pack as closely as possible. If possible, secure the stems to the bottom of the box by means of string. Line the box with tissue paper and put another sheet on top of the flowers. They should now arrive in perfect condition, but in case of lengthy postal delay, tell your friends to plunge the stems into very hot water if they arrive looking limp, and they will revive remarkably well.—K. B.

Taking Cuttings.

Now is the best time of the year for taking cuttings of various soft-wooded plants and in doing so one of the things to avoid is the bruising of the stem of the cutting by making it with a blunt knife.

For making a good, clean cut I have found nothing to equal a disused safety razor blade. Being thinner and sharper than the ordinary pocket knife it does not require as much pressure in making the cutting, and consequently minimises the risk of bruising the stem.

With a little ingenuity a handle can be made to take the blade, or with some types of razor the ordinary razor handle could be adapted to answer the purpose quite well.—H. A. H.

Removing Tomato Stains.

Gardeners growing tomatoes in any quantity are always faced with the unpleasantness of stained hands after they have been attending to the plants. It is not generally known that a few loganberries or raspberries, crushed in the hands, and used as "soap," will entirely remove the stain, if the hands are afterwards washed in the ordinary way with clean water.—L. A. R.

A New Life for Old Poles.

Old poles, which have been in the ground some time, may be given a new lease of life by digging out a small hole a few inches deep round each and then filling it up with concrete, bringing it well above the ground level. When the concrete has set, it can be painted with flat brown paint.—N. B.

THE GARDEN

VOL. XCI.—No. 2911. SEPTEMBER 17, 1927. PRICE TWOPENCE.

CLIMBERS FOR NORTH WALLS

AT one time in quite a number of gardens it was no uncommon thing to see north walls and fences neglected, if not altogether bare of climbing plants. If you were curious enough to ask the cause of this, you would probably receive the reply that it was too cold and shady for plants to grow, but in many instances no attempt had been made.

To-day this is no longer the case, and we see in all parts of the country, walls, even in exposed positions, covered with foliage and flowering plants that in their season are a source of interest and attraction. It is true we are limited in our scope, yet there is enough variety, and the difficulty is to select what we like best. In a few weeks hence we shall be in the planting season, when one may with safety set about transferring things to their final quarters. Before removing any plant, however, there must be preparation of the soil. A good rooting medium for climbers is essential. This is rarely found close to walls, as it seems a common practice everywhere for builders to deposit the remains of rubbish there. It will be obvious to the most inexperienced that a climber intended to remain in one place must in the first instance have something better than the flotsam and jetsam of a builder's dump, and while some of it may be useful 3ft. or so below the surface, above that line there must be provided proper soil in which roots may thrive. In these circumstances it is well to examine the ground, and if the soil is poor or sparse to bring in loam and rotted manure, or leaves.

What to Plant.

We will take plants valued for their foliage first. For quite a number of years the small-leaved forms of the Virginia creeper were always employed, like Ampelopsis Veitchii and A. muralis, until they almost became monotonous, but even these "self clingers" are preferable to bare walls, as for most of the summer at least they clothe with their greenery, while in the autumn the leaves are suffused with deep rich tints, as to make the most unpretentious wall beautiful. There are other things that one may use as a covering for a cold, exposed wall that all the year round give a furnished and pleasing appearance so long as they are attended to.

A consideration of ivies noted for the beauty of their foliage is suggested. If an all the year round furnisher for hiding brickwork and masonry is required, ivies are very suitable. A brief list is given below:

Palmata aurea, yellow.
Atropurpurea, purplish green.
Argentea marginata, green, margined white.
Variegata elegantissima, green and gold.
Cænwoodiana, finely divided foliage.
Chrysophylla, green with yellow blotches.
Lee's Silver, green, with broad margin of silver.

To get the most from ivies, and to have them in their freshest condition, it is needful that they should be clipped annually in March, divesting the plants of all old leaves, shortening the shoots as may be necessary, and doing what nailing up is wanted. Only by this method is one able to keep them in good form and avoid that dingy, drab appearance which must follow when they are allowed to go from year to year untouched.

There is one wall plant that deserves to be seen oftener because of the early beauty of its flowers that come in advance of its leaves. It is well known. It is the winter jasmine, J. nudiflorum, which brightens a wall from December for several weeks with its starry, golden flowers. And we also include the white sweet scented form J. officinalis, the blossoms of which come with the summer days, and though we see it oftener possibly on warm walls and on arches, it is quite hardy, and on a north wall may be a little later flowering. In the large family of the berberis there are those which are evergreen, amenable to training on a wall, and are hardy. They are beautiful in autumn both from a foliage point of view and for their fruit—Darwinii, acuminata and Fortunei may be cited. The hardiness of that very popular Clematis Jackmanni is well known. It will succeed on a north wall once established, though the blossoms may be a little late in appearing. Comparatively few look upon the forsythias from the point of view of a subject for wall covering, yet it has to be said if the shoots are trained out the flowers will come, as is the case with F. suspensa. Who is there who has not at one time or another been attracted by the bunches of fruits of the fire thorns (pyracanthas), those useful evergreen climbing shrubs that are at home on a cold wall and reveal the clusters of berries amid foliage of dark green? Lalandei, with orange scarlet fruit, is one of the most useful. One could add to this list, but enough have been given to show that walls which may be exposed need not because of this be entirely devoid of beauty or left unclothed. Autumn is a convenient time to make plans and to plant any of these climbers.

This Week's Work

For Gardens in the South and Midlands.

Make an autumn sowing of annuals.

Continue to pot up bulbs for greenhouse and room decoration.

Take cuttings of geraniums, pentstemons, antirrhinums and other bedding plants.

Plant bulbs in the rock garden.

Cut out old fruiting wood from loganberries and raspberries.

Earth up celery, plant out spring cabbage, and sow cauliflower seed.

Lift and store potatoes.

Plant peonies, bearded irises and delphiniums.

Top dress and feed lawns.

This Week's Work

For Gardens in Scotland and the North.

Sow seed on bare patches of grass.

Plant bulbs in window boxes.

Earth up leeks.

Continue housing late-flowering chrysanthemums.

Divide old pyrethrums and plant new varieties

Prepare ground for making or replanting herbaceous borders.

Pot up bulbs for succession.

Begin the making of new lawns or greens.

Cut back straggling lateral shoots of wistaria.

Lift and store carrots and beetroot.

Prune honeysuckle directly after flowering if needed.

Select and prepare sites for new rose beds.

SOME MODERN DELPHINIUMS

A Description of the Varieties Constituting the Wrexham Strain.

IN reviewing the evolution of most hardy plants, there is usually some sort or strain which evokes more enthusiasm and creates fresh interest and demand for that particular plant. In such a category may be placed the now famous Wrexham delphiniums. Much has been claimed for these newcomers since their introduction a few years ago, but much also remains to be done by the hybridist before they reach perfection. Out of the many that have appeared of this new strain about a dozen stand out as superior to the others, and these are undoubtedly an advance on anything yet raised. The spikes of these select few possess the true spiral tapering habit, the length of spikes and gorgeous colouring which originally brought the Wrexham delphiniums into favour. The individual flowers are most artistically spaced, just sufficiently to avoid heaviness or thinness, and possess a charm that is not known with the heavy, closely packed hyacinth spike of the older types.

A BORDER OF DELPHINIUMS OF EVERY SHADE.

MRS. TOWNLEY PARKER, A TRUE BLUE VARIETY OF THE OLDER TYPE.

Although an ardent admirer of the Wrexhams, I am by no means desirous of adopting a habit too common with many of our plant raisers, of styling my geese as swans! It would be foolish to claim that all the members of this new type are improvements in every way on the older sorts; for, as yet, I have not seen a hybrid from Wrexham with that perfect form and beauty in the individual flowers possessed by Millicent Blackmore, which variety, although by no means a huge spike, has superiority of form over any other delphinium that I know of which is in commerce. These new hybrids, however, have opened a new field for delphinium raisers by showing to what lengths a spike may reach, and the possibility at once arises of blending the best of the Wrexhams with the best of the older type and thus producing, in time, varieties with the combined virtues of both. From my experience I have found that the finest variety sent out from Wrexham for breeding purposes is Advancement, a variety possessing the true spiral habit with the artistic placement of each individual flower, making, with remarkable regularity, a flower spike of well over 4ft., tapering from a base of 10ins.

Another all important virtue held by this variety is its habit of opening nearly all its flowers simultaneously—a habit happily inherited by the greater proportion of its progeny. It is a delightful shade of pale mauve, in fact, as near pink as I should imagine a delphinium could be. One of the most remarkable seedlings it has produced appears this season under the name of Norah Phillips—a lovely counterpart of its parent, but of a gorgeous shade of gentian blue with scarcely any mauve at all. This brings us in contact with another point for discussion in the modern delphinium. When one speaks of delphiniums one usually visualises a blue flower; yet, how many of our modern varieties may be described as true blue? Of recent introductions, Mrs. Townley Parker, is the most gorgeous true blue of all and if only its flowers were semi-double and of decent form, it would indeed be an advance in the improvement of colours in delphiniums. Take all the giants of recent years—Sir Douglas Haig, Purple Splendour, Wales, Jenny Jones, Countess Cowley Mrs. Foster Cunliffe and even Millicent Blackmore—where is a true real blue self? One has to resort to such sorts as Blue Bird, Blue Boy and Lord Lansdowne to find real blues and each of these varieties are pure singles. I would not for a moment suggest that mauve should be eliminated, for it is undoubtedly a fine shade if grown in contrast with pure blue sorts and preferably light shades. One has only to possess a little of the artist and attempt to stage a group of modern delphiniums in order to realise the great need for true blues of good quality, for without them a mass of mauve delphiniums in the shade of the floral tent gives a somewhat dowdy appearance. At a recent meeting at Vincent Square I was greatly attracted by a group which stood out from the others (and there were at least four well known delphinium firms exhibiting), on account of the delightfully refreshing cleanliness of the colours—granted the spikes may not have been up to exhibition standard, but they were real blues

COQUETTE, A WREXHAM DELPHINIUM WITH TAPERING SPIKES OF VIOLET AND BLUE.

Digitized by Google

and stood out very brightly in contrast to the somewhat monotonous tones of mauve which overburdened the groups of the others. It needed but little imagination to visualise the effect of a similar group with larger spikes and flowers of better form.

Turning to the matter of varieties, I would not care to say which are the best of the Wrexham sorts, for what pleases one taste may not please another. Of the varieties I have myself grown, the following may be given as worthy of comparison with the best of the strain and all have vigour and constitution and are as easy to propagate as any of the older sorts.

Cambria (pale blue and mauve), Coquette (violet and blue), Joy Bells (rosy mauve and blue), Jenny Jones (violet and gentian blue), Monarch of Wales (deep blue and reddish mauve), Queen Mauve (pale blue and pinkish mauve), The Bishop (deep blue with white eye), and Violet Queen. Although the individual flowers are not of ideal form, Violet Queen possesses a shade of colour which appeals to nearly all who have seen the beauty of its long tapering spike evenly furnished with florets of pure violet tinged with ruddy mauve. It is, indeed, a thing of beauty when seen towering above its neighbours in the July border.

When reading these few remarks on the Wrexham and other delphiniums, it should be remembered that my aim has been purposely to criticise and select a few sorts of the newer ones for the guidance of those who have not yet grown them; also, I have tried to show where they both lack virtues, the attainment of which must bring to them a still greater popularity. G. A. P.

SINGLE ROSES: THEIR GRACE & BEAUTY

A charm of their own is possessed by single roses. There are single hybrid teas suitable for bedding, single climbers for arch or pillar, as well as varieties which will soon clothe a pergola.

THE introduction of single roses years ago gave us a new class. It cannot be said that they were received with open arms, as at that time single blossoms were looked upon as unorthodox, and not a little prejudice stood in the way of their popularity. But this only obtained for a while, as they won their way into many a garden and captivated gardeners who at first had been indifferent to them.

One has only to pay a visit to a few shows where roses are exhibited to be convinced of the fact that they have now reached a high standard of excellence, and have certainly come to stay. Particularly is this to be seen among table decoration exhibits, their light, graceful blossoms earning for them commendations from the public thronging the place where they are displayed.

Roses for the Home.

Just as they attract by the simplicity of their blossoms, so do they appeal to that wider circle of growers who love to have their rooms and tables made bright and tasteful by roses that ask but simple culture and are not judged by size of individual flowers. Some of them, as we know, are to be admired for the beauty of blooms growing on dwarf plants; others give us lavishly of charming clusters nestling amid green leaves on pergola or arch; while one may, if it is desired, have porches or window frames garlanded with flowers that are a joy to behold.

Earlier and Later Introductions.

Unlike some other flowering plants—the chrysanthemum, for example—roses do not rise and fall in popularity in a few years, and it speaks much for single roses when it is remembered that some of the varieties first introduced are with us still, and enjoy a good measure of popularity. In this category mention may be made of Carmine Pillar introduced by Paul and Sons more than thirty years ago, still one of the best free-growing and free-blooming roses for arch, wall or pillar, giving immense quantities of blossoms of a rich carmine. It is one of the first to flower.

Single Roses for Various Positions.

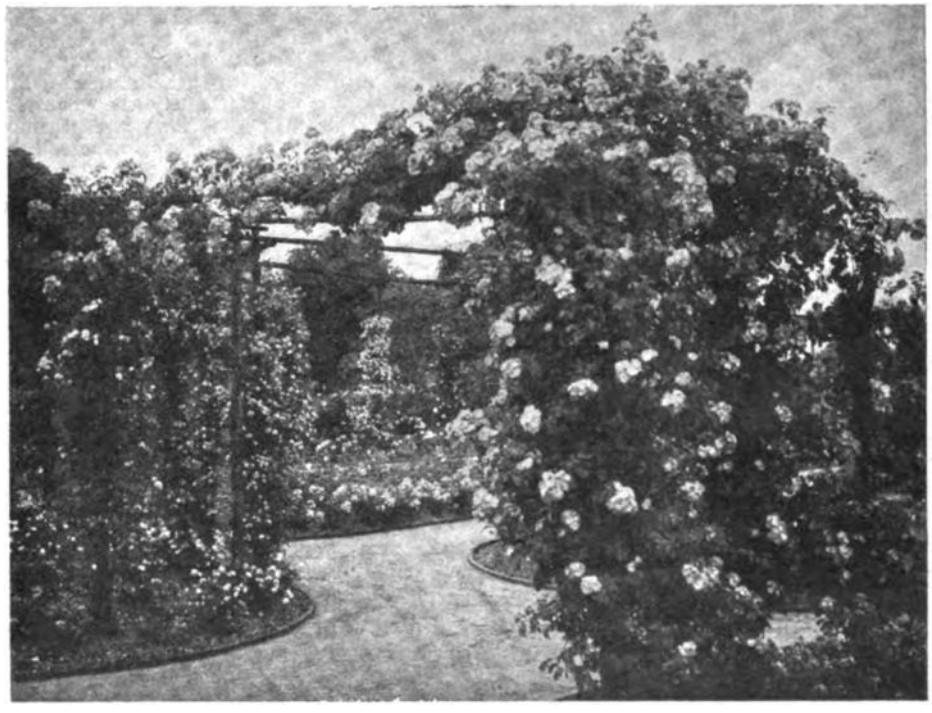
A consideration of single roses, and their value for different positions in a garden, is suggested, and to those who are favourable to growing dwarf sorts in beds of one colour, the singles cannot fail to appeal, as they are noted for their lavish output and diversity of colours.

For beds and borders we have, among singles, some that are very charming, and, in thinking of sorts in my own garden, one cannot but remember how much we owe to Irish firms like Messrs. Dickson and Sons and Messrs. McGredy and Son for their introductions. Some half-dozen are to be found in:

Hybrid Teas.

Irish Elegance, orange scarlet.
Irish Beauty, pure white.
Irish Brightness, crimson, shaded pink.
Irish Glory, rose pink.
Irish Fireflame, orange, flushed crimson.
Irish Afterglow, tangerine in the bud, opening to a tint best described as crushed strawberry.

Two others from Messrs. McGredy and Son are worthy of note—Isobel, a dwarf



AMERICAN PILLAR, ONE OF THE BEST ROSES FOR ARCHES.

of vigorous growth, with long tapering carmine buds which develop into large flowers of great beauty; and Ethel James, of more recent introduction, dwarfer than the preceding, the flowers larger, embracing tints of orange and flame and carmine, an altogether beautiful variety. Among other sorts of single hybrid teas are Mrs. Oakley Fisher, of a rich orange yellow and sweetly scented; Innocence, a pure white yielding many large individual flowers; and Princess Mary, a deep crimson scarlet with yellow anthers. My experience, however, with the last-named sort is that the blooms lack stamina, and, unless shaded from the sun, are of little service for cutting, as I have not found it to be possessed of the staying power so necessary for table decoration. Of course, it is generally understood that roses for cutting should be selected and gathered first thing in the morning, while the dew is upon them if possible, and this applies particularly to the singles.

Single Roses as Climbers and for Pillars.

Attractive as single roses are when grown in beds and borders, they are even more so when used for covering walls, fences, pergolas and the like in and about a garden. In this connection one's mind reverts to sorts like Blush Rambler, that for nearly a quarter of a century has never failed, summer by summer, to yield masses of its apple blossom-like clusters in the greatest profusion. Mention has already been made of Carmine Pillar, and American Pillar, with flowers of a rose pink borne in clusters, blooming at midsummer and lasting for weeks, is never more at home than when clothing a pillar or arch. The evergreen Mermaid is a sulphur yellow with amber stamens, and is a continuous bloomer from early summer to late autumn, and the flowers are enhanced by a wealth of deep bronzy green foliage. These four are useful in almost any position in a garden, often doing as well on an exposed wall as in a more sheltered position. It is upwards of twenty-five years since Hiawatha first made its appearance, a valuable climber among the singles. On purchasing it from a local nurseryman, he expressed his opinion that it lasted in bloom longer than any other variety. It has lived up to its reputation, as it is not unusual for

Digitized by Google

the trusses to remain in a good condition for three or four weeks. In colour it is a deep crimson, with yellow anthers. When the anthers drop it leaves a white centre. At the time this note was written, one in my garden was showing its clusters for the twenty-fifth year in succession, and every season one has to cut away the old rods to enable the new ones to grow, and to keep it within reasonable limits. A garden where roses are grown cannot in these days be regarded as complete without some of the singles. Their colours are varied and their form charming; single roses look most effective either for house decoration or for clothing a pergola or arch. CLAREMONT.

HOW TO TAKE GERANIUM CUTTINGS

In order to have a good supply of bedding geraniums (pelargoniums) for next year, cuttings should be taken now. Full details on how to increase your stocks are given here.

THE amateur who has at his disposal a greenhouse from which frost can be excluded can easily raise enough geraniums to satisfy his own requirements, providing he sets about the task of propagation

A SUITABLE SHOOT FOR MAKING A CUTTING.

in the correct manner. Mid-September is without a doubt the best time to insert cuttings of these plants, although it may appear to be something akin to sacrilege to spoil flower-beds by taking cuttings at this time. Nevertheless, such a sacrifice must of necessity be made if the best results are to be obtained, unless the alternative course of planting out a special batch of plants to provide cuttings has been followed. This latter is an excellent plan and one that should commend itself to all who raise their own stock of bedding geraniums. Plants intended for this purpose should be planted out in firm and not over-rich ground in an open, sunny position, these conditions favouring the production of the best kind of propagating material.

Select firm, short-jointed growths from 3ins. to 5ins. in length and cut them cleanly across with a sharp knife immediately below a joint, taking care that the tissues are not unnecessarily bruised. The lower leaves should then be trimmed cleanly away.

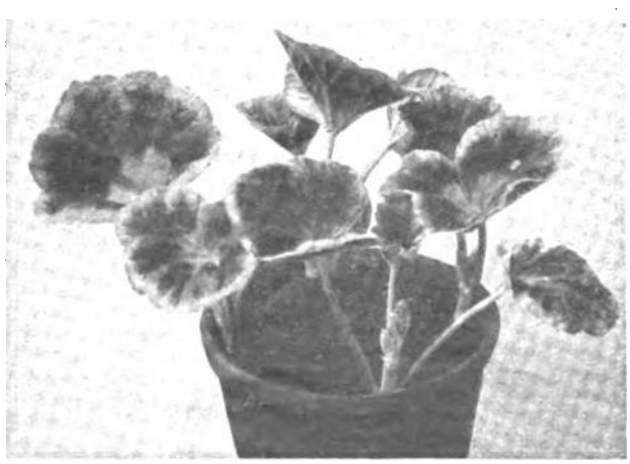
Many growers advocate leaving geranium cuttings lying in the sun for twenty-four hours prior to insertion, until they become quite limp and flaccid—a procedure which they claim removes the superfluous moisture from the tissues and thus lessens the risk of damping off. Personally, I quite fail to see that this can make any difference, for immediately the cuttings are placed in damp soil they commence to absorb water, until the cells of the plant have regained their former turgidity and the water content is as before. I am inclined to think that the only possible benefit which can result from the drying off of the cuttings is accounted for by the fact that they shrink somewhat in the process, and immediately they absorb the moisture from the soil they swell again, and this tends to tighten them in the soil—a most important detail if a good strike is to be ensured.

The compost in which to place the cuttings should consist of sifted loam, leaf-mould and sand, with a preponderance of the latter ingredient. Where possible it is advisable to insert each cutting separately in a small thumb pot, but where this is not convenient five cuttings may be placed around the side of a 4in. pot or six around a 5in. pot. Cuttings placed close to the sides of a pot root much more readily than if placed in the centre of the body of soil. A good sprinkling of sharp sand should be placed on the top of the compost in the pot, so that when the holes are made with the dibber a little falls into each for the base of the cutting to rest upon. See that the compost is pleasantly moist and moderately firm. Use a blunt-ended dibber and make the holes just deep enough for the base of the cutting to touch when inserted to the requisite depth, and then firm the soil well around the cutting so that it will not easily pull out, but take care that the cutting is not "hung" with an air space below it. When the pots are filled water them well with a can fitted with a fine rose. This settles the soil. Stand the pots on a bed of ashes in a cold frame—no shade from

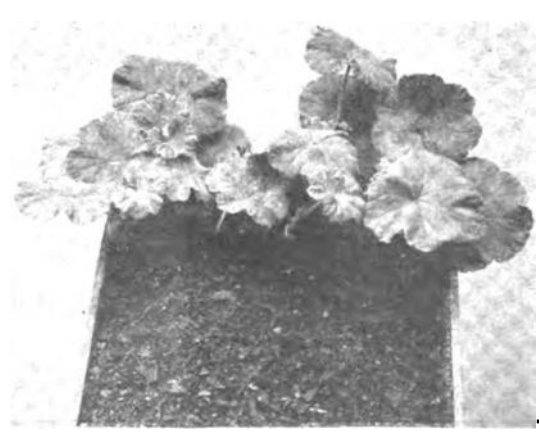
THE CUTTING PREPARED FOR INSERTION.

sunshine will be necessary. At intervals carefully look over every pot and water those which are very dry; but they must never be allowed to become dust dry, while overwatering is fatal. Dead leaves should also be removed. If a frame light is not available, they will root quite well in the open, the only adverse condition being heavy rains and thunder storms.

At the end of September or early October remove to a position in the greenhouse where they are near to the glass. During the winter only water when absolutely necessary, and in February they will commence to grow and require repotting and growing on in readiness for the approaching season. T. H.



CUTTINGS INSERTED ROUND THE EDGE OF A POT FILLED WITH SANDY SOIL.



WHEN A LARGE NUMBER OF PLANTS ARE REQUIRED THE CUTTINGS MAY BE PLACED IN BOXES.

BULBS FOR BOWLS

Successful Culture in Fibre. Little Difficulties which Trouble Amateurs.

BULB-GROWING in bowls of fibre is probably the most democratic branch of horticulture in existence at the present day, for this fascinating hobby appeals to all classes of the community. Its pleasures may be shared by the cottager in the country and the gardenless tenement dweller whose lot is cast in the drab places associated with large towns and industrial centres of activity. Each and all are inspired by the desire to brighten their homes during the days that are short and sunless, and cut flowers are scarce and selling at prices beyond the resources of many a purse. Being comparatively cheap, bulbs are a good investment. Four shillings spent on cut flowers at Christmas or the New Year does not go far, but an equal outlay would purchase sufficient bulbs of daffodils, miniature hyacinths or tulips to furnish three or four bowls and the period of bloom would extend over two or three weeks. Here is the way in which that proportion would work out:

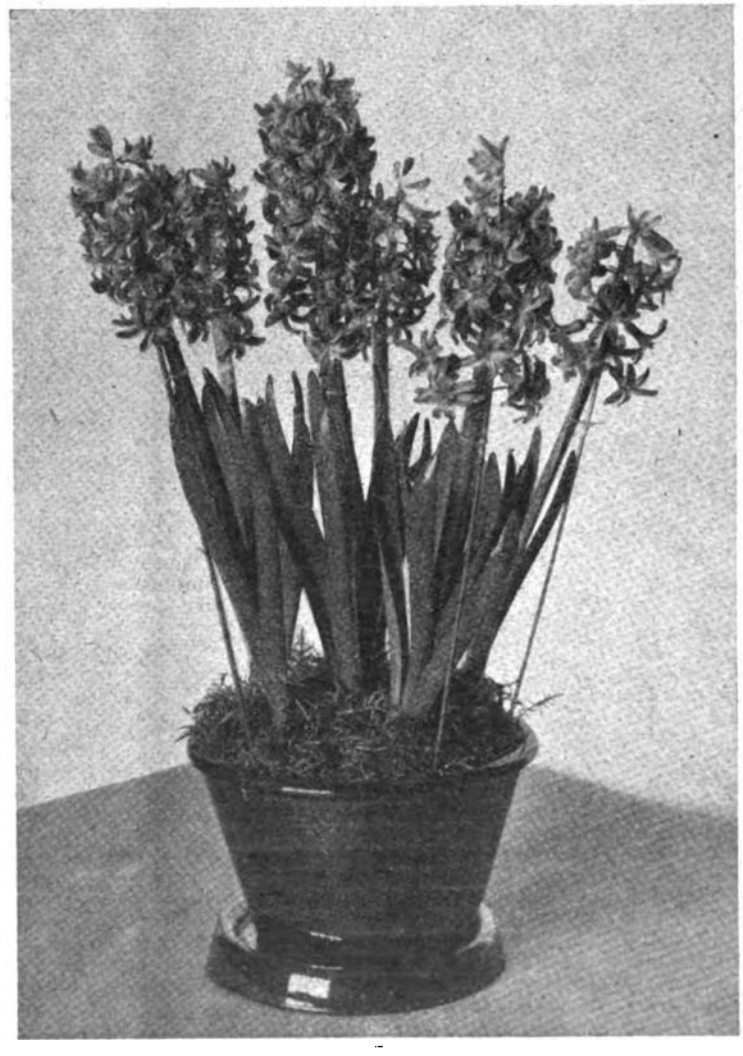
	s.	d.
No. 1 bowl 6 daffodils Golden Spur ..	1	0
No. 2 bowl 9 daffodils Barrii Conspicuus ..	0	9
No. 3 bowl 6 miniature hyacinths	1	6
No. 4 bowl 6 Duc Van Thol tulips ..	0	9
TOTAL ..	4	0

Prices vary, of course, and in some cases larger sized bulbs may cost a little more than is indicated above. If the bowls were planted in pairs at an interval of two or three weeks, the extent of the flowering period would be greatly increased.

Another point in favour of growing bulbs in bowls of fibre is simplicity of culture. Tulips are a little more difficult to produce successfully than daffodils or hyacinths, but the process in either case only involves a little care and attention, particularly during the few weeks [the bulbs are kept in the dark while the root system is in course of formation. First class flowers are only obtained when the roots are properly devolved and in nine cases out of ten failure may be traced to the absence of moisture during the earlier stages of growth. Once the roots are allowed to become dry they receive a check from which they never properly recover. The presence of stagnant water is also injurious and if these extreme conditions are to be avoided, the bowls should be inspected at regular intervals and water applied about once a week. A good plan is to soak the fibre thoroughly and after allowing the bowl to stand for a few minutes, run off the surplus water by tilting the bowl with the left hand and place the right hand over the surface to keep the material in position.

A not uncommon cause of complaint is the tendency to dwarf flowering on the part of hyacinths and tulips. This is generally caused by the premature removal of the bulbs from the dark to full exposure to the light in a heated room. To obviate such a defect the plants must be kept heavily shaded from the time they are brought into the warmer atmosphere of the living room until the buds begin to show colour. By that time the bowls can be placed at a window and a little more water can be given with safety. Always use tepid water, as the flowers will appear earlier by that method of treatment.

When planting bulbs it is essential that the fibre should be thoroughly moistened. That object may be simply accomplished by placing the material in a pail or deep basin and kneading it well as the water is added gradually. In this way it becomes uniformly moist throughout and when transferring the fibre to the bowl a gentle pressure of the hand will squeeze out any surplus water. The depth of the bottom layer will depend on the size of the bulbs, but in any case a space of half an inch should be left at the top to allow for watering. Press the fibre round the bulbs, but do not leave the surface too firm as the bulbs are apt to be forced upwards when the roots begin to develop.



MINIATURE HYACINTHS MAKE AN ATTRACTIVE COLOUR DISPLAY.

Varieties to Grow.

The catalogues of seedsmen who specialise in bulbs contains a wide choice that will satisfy every taste. Prepared hyacinths are generally used for early bloom and planting should be done as early in September as possible. The miniature forms are more satisfactory then the white Roman hyacinths which cost double the price and when grown under favourable conditions the former produce lovely spikes with a variety of colours almost as early in the season as the latter.

Large flowered hyacinths maintain their popularity and the following are representative of the best varieties: Edith Cavell, pure white, combines all the good qualities of L'Innocence and La Grandesse; Czar Nicholas, pretty porcelain blue; Grand Maitre, deep lavender with large handsome spikes; City of Haarlem, one of the finest of the yellows; Pink Delight, lovely shade of soft pink; La Victoire, brilliant scarlet; and Jacques, pale rose with large pyramidal flower spikes that sometimes measure 12ins. in length.

The ten divisions into which daffodils are classified provide great variation in the form and size of the flowers and to provide a succession of bloom on till spring the bowls should be planted at intervals from now until the middle of November. For bowl culture readers are recommended to make a selection from the undernoted sorts:

LARGE TRUMPET. — Horsfieldi and Victoria of the cheaper priced bi-colours; Weardale Perfection and Olympia, more expensive and refined; Emperor, Golden Spur, Glory of Leiden and Cervantes, low priced yellow forms; and King Alfred, a noble yellow of great size and substance; Mme. de Graaff and Mimi, white trumpet varieties.

INCOMPARABILIS. — Lucifer, Sir Watkin, Gloria Mundi, and Orange Sulphur or Primrose Phœnix.

BARRII. — Conspicuus, Albatross and Seagull.

POETICUS. — Glory of Lisse, Ornatus.

POETAZ HYBRIDS. — Laurens Koster, Helios, Admiration.

The Duc Van Thol tulips of dwarf habit are easily forced in the living-room with only gentle heat, but for later bloom any of the following varieties may be planted during the ensuing two months:

SINGLE.—Cottage Maid, rose pink shaded white; Kaiser Kroon, crimson scarlet with yellow margin; De Wet, golden yellow flushed orange scarlet, a sport from Prince of Austria; Proserpine, carmine rose; Thomas Moore, terra cotta; Pink Beauty; Red Admiral; Vermilion Brilliant; White Hawk; and Prince of Austria, orange scarlet.

DOUBLE.—Couronne d'Or, golden yellow flushed orange; Toreador, chestnut red edged orange; Vuurbaak, scarlet: Peach Blossom and Tea Rose, primrose yellow flushed scarlet.

J. Y.

THE BUSY MAN'S PAGE

Work to be Done Now.

IN THE FLOWER GARDEN.

WITH the summer bedding almost over, it is advisable not to delay with the replanting of spring bedding subjects. Bulbs, such as hyacinths, snowdrops and narcissi should be planted as early in September as possible. They make very effective schemes, either in beds by themselves or interplanted with forget-me-nots, polyanthus and pansies. A charming combination is one where pansies form the outside edging of the bed, polyanthuses in the centre of the bed and narcissi spaced equally between them. Wallflowers in many beautiful shades and in early and late varieties can now be purchased. Cheiranthus Allionii, a species of the wallflower, of a brilliant golden yellow colour, will prove invaluable and will give much pleasure and satisfaction when once grown. It is suitable for a bed where it will not interfere with the arrangement of summer bedding schemes, as it is later coming into flower in the spring than the wallflower. Beds should be dug over as deeply as possible, and enriched with old decayed manure where the bulbs are to be planted, and only lime added to the soil where the wallflowers are to be planted. Plant tulips and hyacinths 6ins. deep, but narcissi 7ins. or 8ins. deep.

IN THE FRUIT GARDEN.

Raspberries and Loganberries.—As soon as the fruits of these are gathered, pruning can be done by completing cutting out the old fruiting canes, leaving two or three of the new canes to each "stool" or plant of raspberries and six or seven new shoots to a plant of loganberries. Each cane should be spaced out 6ins. apart and tied up securely to a 5ft. high wire support. Loganberries can with advantage be trained fan-shape, as it enables the fruit to be most easily picked, and also sun gets access to the berries, producing earlier ripening.

Currants.—By cutting out as much of the old wood as possible after the fruit is gathered, more light and air is given to the production and ripening of the new shoots. Pruning should be done with a sharp knife, and as clean a cut as possible made to prevent diseases setting in. The old fruiting wood is easily recognised by its dark colour in comparison with the light colour of the new wood.

IN THE KITCHEN GARDEN.

Spring Cabbage may continue to be planted out during the month of September, 18ins. between the plants and 2ft. between the rows.

Leeks that are showing signs of growth may be fed with liquid manure water twice a week.

Lettuce.—A good sowing of the cabbage variety Early Snowball and such-like early varieties should be made during September in shallow drills 6ins. apart, to provide an early spring supply.

Early planted *celery* should now receive its second earthing-up, late planted varieties their first earthing-up. The leaves of the plants are bunched in close together and firmly tied in one or two places with raffia. To obtain a perfectly blanched plant, each plant is then surrounded by a sheet of paper and tied again, and then the soil on either side of the celery trench mounded up round the plants, leaving only 4ins. of the plant above the mound in the early varieties and about 9ins. in the later varieties.

Spinach.—A sowing of the prickly spinach may yet be made during September, in shallow drills made by the hoe 1in. deep and 1ft. apart.

Strawberry planting should be completed this month.

Raising Pentstemons and Antirrhinums from Cuttings.

THESE should be taken when the plants are finishing their flowering season from the sturdy side growths. A wet year like this does not suit many flowers, but the hybrid large-flowered pentstemons, as well as the smaller bedding kinds, seem to have done well everywhere.

While pentstemons may easily be raised from seeds, there is no difficulty in raising them from cuttings. This is the method to follow where it is desired to increase the stock of a particular variety. Sturdy side shoots some 4ins. long may be taken this autumn and inserted in boxes of sandy loam placed in frames. Do not crowd the cuttings too closely together. After a few days with the sash of the frame shut, give full ventilation with some cover protection all winter; at all costs avoid damp. Several varieties which are of outstanding merit are noted. First of all, the bedders, Newbury Gem, N. White and N. Pink are really grand; Southgate Gem is equally good, Middleton Gem even better than Newbury Pink, its nearest type. In the hybrid, large-flowered kinds I name as first-class Castle Forbes, Blushing Bride, Countess of Minto, Alex. McRae, Crimson Gem, Lady Northcliffe, Earl Haig, D. McKinnon and William Smith. Very good also are Fairy Queen (from seed), Paul Cambon, Thos. Simpson, Lord Kitchener, Charles Street, Duchess of Atholl, Tullibardine, Mrs. R. Fleming, Mrs. A. Forbes, John Forbes and Lady Hamilton.

CUTTINGS OF PENTSTEMON AND ANTIRRHINUM.

Although most growers raise antirrhinums from seed in autumn or in spring, the older plan of striking cuttings must never be overlooked. Cuttings root easily, and should be treated in the same way as pentstemon cuttings. The plants obtained, also, are hardy and can be planted out at the earliest opportunity in spring, while it must never be forgotten that they flower in advance of ordinary seedlings. Not only does this plan save labour and greenhouse space, in the case of spring-raised plants, but it will readily be admitted that it is a sure plan when colours are required true and uniform plants desired. From the middle to the end of September is probably the best time to take the cuttings. Ordinary garden soil, with, perhaps, the addition of a little sand and leaf mould, is quite satisfactory. Cuttings are plentiful in the form of flowerless side shoots, some 3ins. or 4ins. long, and these may be dibbled in, not too closely, in the boxes. Rooting is speedy and, after the plants have been kept close for a week, full ventilation may be given; indeed, the frame sash during the greater part of the winter may be kept tilted, fore and aft. One or two waterings during the winter generally suffice, and overdampness must be avoided.—H. A.

Replenishing the Salad Bowl.

OPPORTUNITY should now be taken to sow quick-growing crops suitable for salads, such as lettuce, radish, mustard and cress. Of the two latter frequent sowings are preferable and, if possible, under glass, as the quicker grown the better, warmth and moisture being the main conditions. For lettuce and radish the soil should be in good condition in order to produce quick results and succulent growth. If the ground is free from twitch and such-like root weeds, the seed may be sown broadcast, the larger plants being used first. Two or three applications of nitrate of soda greatly encourage growth. It should be applied in showery weather or watered in. Lettuce for early spring use should be sown in a frame or sheltered position. Tom Thumb is very suitable for this purpose. Endive and chicory, although not so popular, need to be protected from frost and snow. Late summer salads comprise the additional advantage of variety, as such good things as tomatoes, cucumbers and beetroot are available.

Rooted Carnation Layers.

WHERE the garden soil is of a sandy nature, the layers may be left attached to the parent plants throughout the winter months, or they may be transplanted forthwith into their flowering quarters. But in gardens where the soil is cold and retentive of moisture, the best plan is to sever the rooted layers in due course and transplant them into a cold frame or into a prepared nursery bed where some temporary protection can be afforded when severe frosts come. At the end of March or during the first half of April the final planting may be done. Autumn planting is best where everything seems favourable to it. Carnations succeed better in good than in poor soils. They are, however, very impatient of fresh manure if their roots come into direct contact with it. When engaged in digging and manuring the soil, be sure that rotted manure is used and so buried in the soil that it will be at least 4ins. below the surface. The roots of the young plants will not come into contact with it before they become active the following spring, when they will be much benefited. Do not tread on the soil of the border after the rooted layers are planted. Keep the surface soil hoed.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Outdoor Bulbs.

THE spring garden may be either a vista of loveliness, or merely a dreary waste, according to whether there is a good display of early bulbs or not. No other plants give quite the same splash of colour, or are quite so certain to bloom. The bulbs should be given a fairly prominent position, and be in view of the windows, for they flower at a time when the garden is largely viewed from indoors. Colour schemes can be attempted by the ambitious gardener, but unless one can be certain of the date of flowering, it is best to confine one's choice to a few varieties, as better effects will probably be obtained.

How to Build a Rockery.

MOST rock plants are resting just now, and this is the time to build or remake the rockery. In or near towns the soil of rockeries tends to become sour, and it is advisable to rebuild a rockery every three or four years. The idea of a rockery is to grow the floral gems from the mountain tops in our gardens. Of course, not all the plants that inhabit the high regions will thrive in the valleys, but a good many will, if suitable soil and situation are provided.

Soil for a Rockery.

Naturally, the soil in the rock pockets and on the ledges of mountains is gritty and well drained. This, then, is the first consideration in building a rockery. Good drainage and plenty of sharp sand or grit in the soil. The type of stone used will depend on the district. Weatherworn limestone is considered best, and those who live near a plentiful supply should use it; but sandstone, flints, and even bricks, cement blocks or clinker can be turned to account. The form of rockery will depend upon the site, size and nature of stone available. Perhaps you can remember a little bit of rock scenery worthy of reproduction. I saw a marvellous model last summer of a Basque valley. Each knoll was planted with rock plants, and even water was introduced, with dwarf aquatic plants to complete the picture. A few points to remember in making a rockery are—to break up the subsoil to ensure good drainage; to make pockets of various sizes to receive plants; to place each stone so that the water drains into the rockery and not off it; and to fill the pockets with prepared soil before planting. A mixture of decayed leaves, soil, sand and lime rubble in equal parts makes an ideal soil for most rock plants.

A WELL FILLED AND CAREFULLY PLANNED ROCK GARDEN.

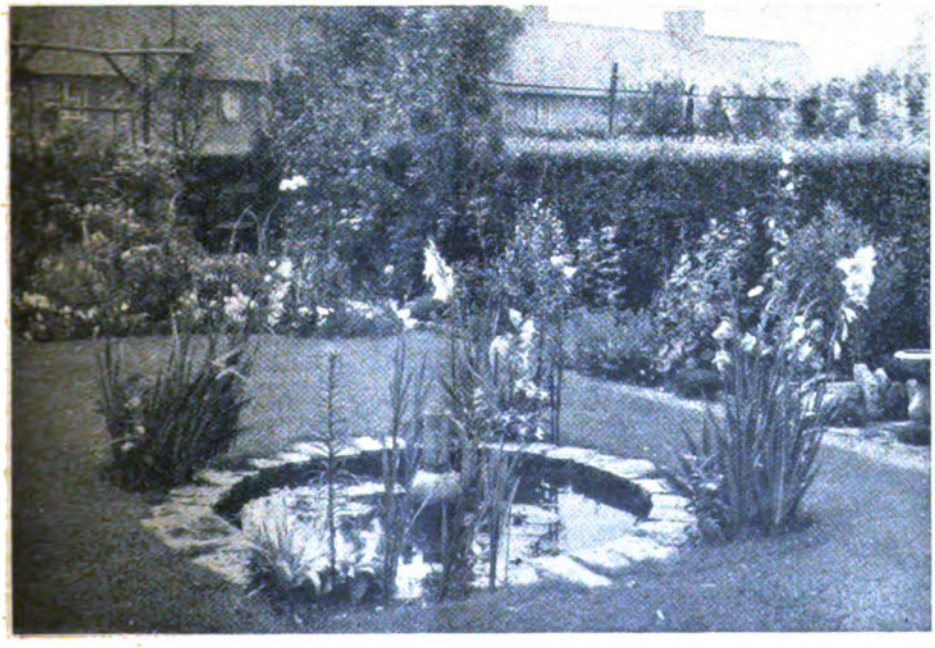
Suitable Plants.

Arenaria balearica creeps over the rocks; aubrietia will hang over the stones; mossy saxifrages, Dianthus alpinus, evergreen candytuft, oxalis and Primula Juliæ are all of value.

An Effective Water Garden.

AS soon as the eye catches sight of a pool of water in a garden one is led instinctively to its side. The reflection of flowers such as are illustrated in the accompanying picture adds to the beauty.

Water gardens are more popular, of course, in warmer countries, such as Italy. They add coolness to the garden. Two of the many new varieties of water lilies that are suitable for the tiniest pools are Nymphæa pygmæa alba and N. p. Helvola. It would be well to plant a few small bulbs of bright colours, *e.g.*, dwarf daffodils like Triandus albus (Angels' Tears), jonquils and grape hyacinths, which show up well against a water background. Of course, polyanthus and primulas are in keeping with the water garden.



A LILY POOL OF SUITABLE DESIGN AND SIZE FOR A SMALL TOWN GARDEN

Greenhouse Flowers in Winter.

THOSE who grow young plants on during the summer so that they shall come into bloom during the winter in the greenhouse must see to it that the greenhouse is made ready to receive them. As early as the middle of September it may be necessary to bring in these plants, for the vagaries of the British climate are such that one cannot be sure that early frosts will not occur by that time. If you have grown plants in frames—such as primulas, cinerarias, genistas, geraniums (zonal pelargoniums), etc.—they have probably been standing in their pots on a bed of moist ashes. When they come into the greenhouse, a similar bed should be made to receive them. By covering the stages with ashes, the plants keep moist, and are less likely to lose vitality as a result of their removal indoors. Ventilate very freely whenever possible, but keep out all frosts, and a fine show of bloom will result.

Daffodils.

THE colour of sunshine in the garden can be achieved even in the dull days, if daffodils are grown. These can be planted in groups in the border, and may be intermixed with other spring plants, such as wallflowers. Lay out the daffodil bulbs on the soil surface, and as you plant put in a wallflower between each bulb. The effect of this is charming. Other spring flowering plants, dwarf arabis, forget-me-nots, or polyanthus, can be used in the same way with bulbs of all kinds.

NOTES ON THE FLOWER GARDEN

Grape Hyacinths for Present Planting.

THE muscari are lovely spring flowers that require no particular culture or soil, and are, therefore, suited to every garden. Known chiefly by the familiar name of "grape" or "starch" hyacinths, they are one of the most beautiful blue flowers we have, if we note the great effect produced by so small a plant.

There are three distinct uses for these lovely little gems. First and foremost, a place on the rockery, well away from any other rambling or overshadowing plant. Here, in little colonies which become more attractive every year, the grape hyacinths provide a very ornamental and colourful effect for a considerable period. Second, as an edging to the flower border in the spring, they can hardly be surpassed, especially if the border is edged with rocks, or bricks on end, which the mass of blue flowers will cover and make beautiful. The third site for the flowers is a piece of short grass, perhaps at the foot of the rock garden, a grassy bank, in little patches here and there on the lawn. As the height of these flowers rarely exceeds 6ins., these three localities are ideal for them, and the grass should be very short in order to exhibit their beauty.

Where many of these flowers are grown, one can often distinguish more than one shade of blue, showing that the bulbs are often sold in mixture; but there are distinct species and varieties that may be worth noting, and even grouping on the rockery.

The best of all is that grape hyacinth most used in gardens—Heavenly Blue, a very apt and true name, for the little globe-shaped bells are of the deepest and clearest blue imaginable. These, produced on long stems, are very fragrant, and can be used as cut flowers; they remain fresh in water for a long time. They bloom from March to May. Hyacinthus azureus (syn. M. azureum) has Cambridge blue flowers and is very valuable for early flowering—at the beginning of February the blossoms will appear, which proves its hardiness. The Italian grape hyacinth (M. botryoides cœruleum) not only possesses blue flowers, but also produces a *white* variety. Two others not often seen but making very interesting variations for the rock garden, are M. neglectum majus, having quite black-blue flowers; and M. plumosus, bearing flowers in feathery plumes of a deep violet hue.—N. E.

GRAPE HYACINTHS ARE MOST EFFECTIVE FOR EDGINGS.

A Decorative Trailing Plant.

Convolvulus mauritanicus.

THIS plant belongs to the bindweed family and hails from the Mediterranean regions, therefore it cannot be considered hardy in all districts. It is such a beautiful subject, however, that it is worthy of a little protection in a hard winter, while it is often an easy matter to retain a few pot plants in a frostproof frame till the spring. Here at Castleford, Chepstow, Mon., it is planted on an elevated part of the rock garden, where the soil is light and more or less stony and well drained. In such a position it survives the winter without any protection, so it may be hardier than we sometimes think. C. mauritanicus is a modest trailer, not by any means rampant, and is, therefore, well suited for the rock garden, especially in warm, sunny positions where the soil is light. The lovely clear pale azure blue flowers are freely produced throughout the summer months, and during August the plants are about at their best. It is increased by cuttings and seeds, the latter being produced in plenty, therefore no difficulty is experienced in retaining a good stock. This plant is also useful for hanging baskets in the cool greenhouse, where its cascades of blossom prove an attractive feature for several months.—B.

C. MAURITANICUS DELIGHTS IN A WARM PLACE ON THE ROCKERY.

Preparing for Roses.

ROSE planting time will soon be with us again. The sites the trees are destined to occupy need careful preparation, so that it is not too early to think of the matter and to start preliminaries. One point needing emphasis is the supreme value of deep digging. The deeper that the soil is dug the farther will the roots travel, to build, as a consequence, sturdy, robust trees, which will yield fine blooms. Dig not less than two spits deep, and if the subsoil can be broken, break it. Rotted farmyard manure should, if possible, be incorporated with the turned soil. Should the ground be of a chalky or sandy nature, it should also receive clay, in which roses revel. With the top soil mix basic slag at the rate of 4 oz. to the square yard. If the ground to receive the roses can be prepared thus in advance of planting by a few weeks, the trees can be expected to do well without needing nourishment other than contained in the prepared soil for a year or more.—A. J.

Scarborough Lilies for the Border.

ONE is so accustomed to seeing the Scarborough lily (Vallota purpurea) grown as a pot subject that few realise the possibilities of the plant for the open border. As a matter of fact, the plant is only seen at its best in this country when growing in a suitable position out of doors. Then the flowers are produced with a profusion which marks the vallota as one of the most splendid plants in cultivation. Of course, as a native of the Cape, the Scarborough lily will not grow well in very cold parts of the country and, in any case, it should be given a warm situation in a light soil, such as at the foot of a south wall. Where such a position is available it would be really worth while planting out any potted specimens. Press the soil firmly round the bulbs and arrange to have the upper part only a little below the surface. A very good time to plant vallotas out is in the early autumn, as they will then have some chance to settle down before the winter. If the bulbs are of good size, there is every prospect that there will be a fair amount of flower in the following summer. Once established the vallotas may be allowed to stay in the same place, as they do not like root disturbance. Every year the clump will become finer and the number of flower spikes produced is often surprising and far in advance of anything that is usually seen when the specimens are in pots. In

Digitized by Google

cold weather, when there is a chance of severe frost, it is an advantage to protect the plants with bracken or light dry litter. Even if the leaves get a little damaged, this rarely affects the bulbs, which at the approach of warmer weather start to grow with great vigour.—S. LEONARD BASTIN.

A Handsome Himalayan Shrub.

Buddleia Colvilei.

THE various forms of B. variabilis are represented in many gardens, but the distinct species quoted above is not met with so frequently, probably on account of its reputation of being tender. It has, however, succeeded for a number of years at Chepstow as a shrub without any protection beyond that furnished by a clump of pine trees, which shield it from the strong west winds. It is a native of the Sikkim Himalayas, and Sir J. Hooker said it was "the handsomest of all Himalayan shrubs"; certainly it is the best buddleia, and quite distinct from all other species or varieties. The plant referred to is about 8ft. high, and in early June it carried a liberal crop of flowers. These are produced in a terminal pendulous panicle 6ins. or more in length, and the large individual blooms are rose-coloured and nearly an inch in diameter. The foliage is silvery-grey, but eventually becomes green, and the flowers have been likened to a rosy pentstemon. In favoured localities it should be planted and treated as a shrub in the border, but in many places it would succeed best as a specimen for a wall with a south or south-west aspect. With regard to pruning, it also differs from the variabilis section, and the non-production of flowers can often be traced to pruning. Many buddleias are cut hard back each spring, but B. Colvilei requires but little pruning, and this should be carried out in strict moderation after flowering. A slight thinning of the growths would, no doubt, prove beneficial, thus allowing plenty of light and air to reach the plant, and thereby bring about a thorough ripening of the wood, which appears to be essential for the production of flower spikes.

This buddleia is a vigorous grower, and will attain a height of 20ft. or more; but for the first year or two it seldom blooms; it evidently needs to become well established before flowers appear.—T. W. B.

THE DISTINCT AND BEAUTIFUL BUDDLEIA COLVILEI.

THE WHITE FORM OF THE ITALIAN SCILLA, S. ITALICA ALBA.

A May-Flowering Scilla.

Scilla italica alba.

THIS pretty little scilla is not so much cultivated as its undeniable beauty deserves. It has charming white blooms, and the plant grows 6 to 8ins. in height. It is perfectly hardy, but prefers a light warm soil. A corner in the rockery should be found for it, and then the bulbs should be left untouched for three or four years, after which time it is desirable to divide and replant them.—C.

The Treatment of Liliums After Flowering.

OFTEN these bulbs are forgotten at the dying of the blooms, the keen interest being maintained only during the growing and flowering stages. This is wrong. We should take great care of the bulbs. All liliums are much benefited by having a good supply of fibrous loam, in which the grass has perished several months, packed round their roots after the flowering stage, where the bulbs are left in. This new loam, applied soon after the flowers have faded, and rotted manure applied in the form of a surface mulch, help to strengthen and protect the bulbs during adverse weather. Liliums grown and flowered in pots should be transferred to the cold frame from the greenhouse or conservatory, where water supplies can be properly regulated as the bulbs need careful treatment at this stage. The lights should be kept on, but tilted to admit air freely.—CHRISTCHURCH.

A Plant Worth Reviving.

Salvia Sclarea.

CLARY is a very old plant of English gardens, where it was formerly esteemed from having some mild medicinal virtues, but its general cultivation is well worth reviving for its fine effect in the flower border. The flower-stem rises to a height of 5ft. or more, and branches out a good 2ft., and all is laden with bract and bloom of a charming colour quality. The large bracts are reddish mauve and the flowers pale blue, or, as Parkinson has it, "a bleake blew colour." The effect in the mass is that of clouds of tender broken colour, both delightful and interesting. The colour of both bract and bloom is apt to degenerate into a whitish tint, therefore I am careful to save seed from the best coloured plants; this is the easier to secure if the lighter-coloured ones are pulled up as soon as the best of the flower is over. This is no loss, as the plant is a biennial; but as they take some space, I keep pots of hydrangea to drop in where any clary comes out. It is apt to sow itself if it is left till the seed ripens naturally, or, as the old Herbal author says, in prettier language than we now use, "Sometimes it will rise of its own sowing." Parkinson also tells us that in his time it was made into fritters: "The leaves taken dry and dipped into a batter made of the yolkes of egges, flower, a little milke, and then fryed with butter until they be crispe, serve for a dish of meat accepted with manie, uppleasant to none."—G. J.

THE OLD-FASHIONED SALVIA SCLAREA (CLARY).

THE CULTURE OF VIOLETS IN FRAMES

HOW very often during the winter months so many garden frames are to be seen idle, and yet with such little cost every inch of space could be utilised to the most profitable account by the cultivating of violets. Although they can be very successfully and profitably grown out in the open, yet with the extra shelter and warmth of a frame, larger stalked and cleaner flowers can be obtained.

About the third or fourth week in September the growth of the plants in the open should be checked by chopping round them with a spade and about the same time the frames should be prepared and made ready to receive the plants. At the bottom of the frame place a layer of clinkers and on top 1ft. of good fibrous loam and leaf-mould in equal proportions.

Lift the plants from the open ground early in October and plant out 9ins. apart in the frame. Keep the frame closed for a few days after planting to allow the plants to get used to their new quarters, then gradually admit air according to atmospheric conditions. The great mistake of keeping the frame too close is often made in the culture of violets, with the result that the leaves and flower stalks damp off. Admit air on all possible occasions throughout the autumn and winter. Excessive watering of the plants should be avoided, but the plants should not suffer from drought, as red spider will at once attack them. Watering should be done, if possible, on bright mornings.

The two great enemies to be combated in the cultivation of violets in frames are: the disease commonly called rust or spot and the pest mentioned above, red spider. The former is recognised by round, brownish spots which appear on the leaves and which wither as the attack increases. As a preventive against this disease, ample space should be allowed between the plants, air admitted during fine weather, the soil kept moist, but not sodden, and after the plants have been flowering for some time, the soil between the plants should be loosened and fresh compost added. Yellowing leaves should be promptly removed.

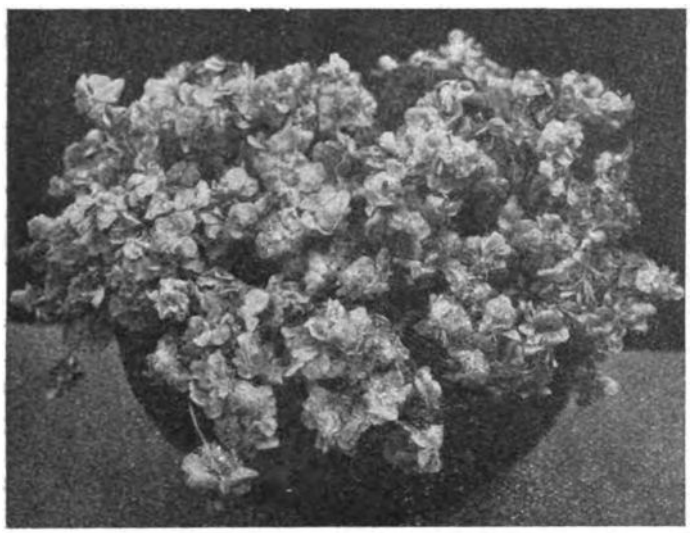
In case an attack appears to be spreading, spraying with Bordeaux mixture, which may be obtained from any horticultural sundriesman, may be tried, but it cannot be relied upon.

Red spider cannot be discerned with the naked eye, but if a plant loses its freshness and assumes a rusty appearance, red spider may be suspected. To remedy this, preventive measures, by keeping a moist, buoyant atmosphere, are much better than the cure. If the cure has to be resorted to, a vigorous syringing of the plants may suffice in the case of a slight attack, but if it does not, a nicotine and soft soap solution should be used, applied with as fine a spray as possible. The solution is made by boiling 1lb. soft soap in 20 gallons of water and stirring in 1½ oz. commercial nicotine and using very hot.

Weak doses of soot and manure water are a good stimulant if applied when the plants are throwing up their buds.

After flowering, as many runners as possible should be induced to grow from the plants and if these are pegged down into the soil and a little leaf mould placed around the base of the runner, rooting will take place freely. These young plants are then detached from the parent and planted outside in the soil about 6ins. apart. This provides the stock for the following autumn. There are several varieties on the market, of which Princess of Wales, Marie Louise and Comte de Brazza are among the best.

If this cultivation is followed up, good violets can be obtained throughout the winter and spring. M. H.



MARIE LOUISE, WITH BEAUTIFUL DEEP-BLUE FLOWERS.

PRINCESS OF WALES, ONE OF THE BEST SINGLE VARIETIES.

PREPARING THE GREENHOUSE FOR WINTER OCCUPANTS

THERE is generally something to do in a greenhouse in the autumn before it can be made ready for the reception of plants which have been growing on for flowering during winter. It may be that, for the past few months, the house has been devoted to dwarf flowering subjects in pots, and it will be necessary to remove the stages for taller plants which will take their places. Or, possibly, the house has been devoted to the culture of tomatoes or cucumbers, which will have to be removed to make way for other things coming on. In any case, the roof should have the first consideration—painting, puttying and replacing any broken panes. If it is not needful to do any painting inside, the sash bars and glass, as well as stages, ought to be thoroughly cleaned, so that all may be ready for the winter.

Should it happen that green fly, red spider or white fly has put in an appearance this summer, this is the time (when the house is empty) to fumigate well with a view to eradicating such pests. At the same time, opportunity ought to be taken to paint with lampblack and linseed oil the heating pipes, to prevent rust. The stove itself should also come in for its annual overhaul, so that when the need for making fires arises, everything will be in order. This work is much better put in hand while the weather is suitable, and one may temporarily remove any occupants out of doors.

Where it is proposed to house chrysanthemums, it will probably be found necessary either to remove existing stages from the house or lower them to ground level in order to accommodate the plants satisfactorily. Roof shelves should also be taken down and cleansed, so that when the time comes for housing small plants, like primulas, etc., their transference from the frame can take place without delay.

The date for housing winter tenants depends largely upon the condition of the weather and locality in which one resides. In many districts, plants in small pots accommodated in frames can be kept there often until well into October; but in the case of chrysanthemums exposed to the weather out of doors, it behoves the grower to "watch the weather" after mid-September, and be prepared to bring them under glass should frosts occur. A definite date cannot, of course, be stated as to when such plants ought to be housed; but, having regard to the trouble bestowed on them since the beginning of the year, it is better to bring plants indoors a few days earlier, rather than expose them to one night's frost which may cripple the buds, even if such early housing means abundant ventilation by day and night, and possibly slight shading in the middle of the day. I have seen more than one batch of plants in the Midland counties spoilt by leaving them out of doors a few days too late, and all the labour of months wasted.

Should the house be a lean-to, the back wall ought to be well brushed down and cleansed with water to dislodge any pests: and if it has been customary to whiten the wall, a coat of lime will generally kill any insects lurking in the crevices. F. W.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

THE advantages of sowing sweet peas in autumn are generally recognised by exhibitors, and as Mr. Smellie and Mr. Unwin agree that late September is the most suitable time in which that particular work should be overtaken in Scotland, growers should make up their minds regarding the varieties that are to be grown and place their orders at once, because delay in delivery is a common experience each year. In this connection a real difficulty arises. It is only in September that the new catalogues are published, and it is the exception rather than the rule for distributing firms in the trade to obtain possession of their stocks at such an early period. At the time of writing Messrs. Dobbie and Co.'s list is the only one that has reached me, and it contains a hint that the prospects of a good harvest are not bright. But be that as it may, the conclusion is obvious, that the modern cultivator of sweet peas in Scotland must conform to nature's laws which regulate harvest and seed time, and in doing so it may be necessary to extend the seed-sowing period beyond the favoured span. While the question is interesting as indicating the apparent divergence between up-to-date theory and practice, it only appeals to a comparatively small number of growers, as spring-sowing is generally followed by the mass of the people who cultivate our most popular annual for decorative purposes.

The method of sowing in autumn and subsequent treatment does not differ in any material respect from that observed in early spring. Pots and boxes are equally suitable provided they are 6ins. in depth, but the latter are generally favoured when a large number of plants are required. As soil conditions are closely associated with germination, care should be taken that the medium is neither heavy nor rich. It is better to err on the light side, for in that direction sweetness and porosity lie, therefore prepare a compost consisting of equal parts of loam, leaf-soil and sand, and if you provide a top layer of the latter material as a seed bed so much the better. A simple rule to be observed in sowing is to regulate the number of the seeds according to the size of the pots, thus a 3in. pot will accommodate three seeds, a 5in. pot five seeds and so on. If boxes are used, sow the seeds in rows 2ins. to 3ins. apart and allow a space of 1½ins. between each seed. Cover the seed to a depth of half an inch, and as each variety is completed attach a wooden tally containing the name and number of seeds, an arrangement that will facilitate the work of checking the germination results. Plunge the pots in ashes or in the soil of the frame, but the boxes are better to be raised above the surface. Keep the lights closed until the seedlings make their appearance in about a fortnight's time, when they may be removed and only replaced during spells of bad weather. Always remember that sweet peas are hardy and should never be coddled.

Messrs. Austin and McAslan, Glasgow, have issued particulars of their spring flower show, which is to be held in the McLellan Galleries on March 14th to the 16th. There are forty-nine hyacinth, narcissi and tulip classes open to gardeners and amateurs, and ten classes for azaleas, cyclamen, cineraria and Primula obconica. The firm provide the prizes, amounting to £50, together with special prizes of £3 3s. each for the best exhibit in the gardeners' and amateurs' classes.

The annual excursion of the Royal Caledonian Horticultural Society took place on September 3rd, when a party numbering over forty spent a delightful afternoon in the gardens and grounds of Arniston, Midlothian. The company were met by Lady Dundas and were taken round by the Factor and gardener. Notwithstanding the recent wet weather, the garden looked exceptionally well, and the flower borders were specially admired. Artistic blending of colours was very noticeable, and pleasing shades were used in the long borders running through the centre of the gardens. After viewing the range of glass-houses the party walked through a portion of the woods and saw the glen, which is a feature of the estate, and were shown two old larches, one known as the "leaning larch" from its peculiar angle. These are old trees over 100ft. high, and are said to be the first planted in Scotland. Tea was served in the mansion, after which the president, Mr. W. J. Thomson, expressed the thanks of the society to Lady Dundas. On the journey home the company also visited the historic chapel at Roslin.

September was ushered in by a spell of delightful weather which opened up the late bloom and created a wealth of colour in the gardens reminiscent of summer at its best. Dahlias, chrysanthemums, gladioli, phloxes and the autumn roses all contributed to the gay picture and banished memories of past disappointments. The brilliant sunshine in daytime is, however, followed by occasional touches of frost at night, warning amateurs of the risks accompanying autumnal climatic conditions and the exercise of prudence in the protection of tender plants. On the principle of safety first a number of chrysanthemums in the border should be potted up and taken indoors while they are in bud. Rambler roses should have attention about the end of the month. Cut out all the dead and old growth on which the withered sprays remain so as to promote the ripening of the new wood that is to produce next season's blossom. It will be noticed that several strong, erect stems have sprung up from the base. In the event of the number being greater than what is required for the future furnishing of the bush, take away the weakest and tie up the remainder securely so that they may withstand the winter's storms.

The first Saturday of September was an eventful day at Mosspark. It was the occasion of the flower show formally opened by Lady Malcolm Campbell, and the first public recognition of the success of Mr. James Stewart in retaining for Mosspark the custody of the *Daily Record* championship trophy awarded to the best-kept garden in the housing schemes of the Corporation. The Campbell Cup awarded to Mr. D. C. Williamson for the best bank of cut flowers, and the Society's challenge trophy won by Mr. J. R. Smith for dahlias were presented.

WHAT OUR READERS SAY

A TEST OF LAVENDER SWEET PEAS.

SIR,—For some years I have been greatly interested in growing lavender-coloured sweet peas, side by side, as each new variety of this particular shade of colour has been introduced. Last year I thought I had found just what I wanted in Austin Frederick, a flower of great beauty in my estimation from every point of view of what a sweet pea flower should be. This year I sowed a packet of "Mermaid," thirty seeds, twenty-seven of which gave strong, vigorous growths, and the result has been far beyond anything I ever remember to have seen in a lavender colour. The purity and depth of rich pure lavender, of the blooms, which are large, waved, and have on nearly every stem four flowers and very many five, has at last given me a type of flower which, I should think, has come to stay. In any testing of either flowers, fruits or vegetables, I give the most thorough attention to every detail, so that my conclusions shall be not only satisfactory to myself and my future work, but also a true guide to others who seek to know the best. Gardening as a profession is as fascinating to me at the end of fifty-five years as ever it was, but if there is one branch more interesting than another it is the testing of types of what takes one's fancy, side by side, either in the greenhouse, garden, orchard, shrubbery or plantation.—V. H. LUCAS, *Hurworth-on-Tees, Darlington.*

A DWARF PENTSTEMON FOR THE ROCKERY.

Pentstemon Davidsonii.

SIR,—This little shrubby pentstemon, which I first saw on its earliest appearance at Chelsea Show, has been the subject of considerable difference of opinion respecting its correct nomenclature. I have no intention of entering upon this vexed question, and this is all the more unnecessary, seeing that the plant can be procured most easily from nurseries by asking for P. Davidsonii. It is worth obtaining as it is a plant which has several attractions, although the purist in colour tones will possibly have faults to find with those of the blooms. But much may be forgiven such a pleasing little plant, even if its red flowers have more of that mauvy tone for which some of us care little. Yet this little shrublet, not more than an inch or two in height, has a decided attraction, and its toothed leaves of light green, together with these bugle-like flowers, look really well rising from a moraine or from a sunny crevice of the rock garden. I came upon an exceptionally good plant of this gem in a moraine of river gravel the other day, and its bright colouring seemed toned down by its surroundings as to make it all the more pleasing. A granite moraine has been recommended for it, but this does not appear to be necessary. It is propagated by cuttings which strike freely under glass.—S. ARNOTT, *Dumfries.*

THE CAUSES AND REMEDIES OF FRUIT SPLITTING.

SIR,—I think that most gardeners will agree that cases of fruit splitting occur more in a wet season than in a dry one. When fruits are growing inside, as peaches, tomatoes, melons and grapes, splitting is quite under the grower's control; outside, it has to be left very much to chance. In the case of outside fruit trees or tomatoes charged with an excess of moisture, splitting will occur in a season like the present. Our object should be, where fruit is maturing, to ward off excessive moisture. The fruits named above if grown inside should have no check while growing to full size; when this stage is reached, lessen the supply of water and moisture in the house, and allow air to circulate through the house night and day. If this is

Digitized by Google

done, splitting is reduced to a minimum. Tomatoes can be picked when just coloured, after which the plants can be watered again. Grapes are the most troublesome, especially if the borders are partly or entirely outside; to remedy this, I always place spare lights over the outside border to throw off water as soon as the grapes are just coloured; this makes the outside as dry as the inside, and, with full ventilation in the day and the ventilator open a crack top and bottom at night, seldom does a berry split. The aim should be to keep plants on the dry side when fruits have reached maturity.—G. WALLER, *Surbiton.*

TENNIS BOUNDARY NETS.

SIR,—A short while ago the practice of taking out a strip of turf alongside the netting surrounding a tennis court was recommended in THE GARDEN as a means for keeping the edges of the grass neat. If this space is kept well hoed, it certainly does improve the appearance of the court; but to tennis players it has the serious drawback of making the balls very dirty, especially in damp weather. In my humble opinion a far better method is to fix the bottom roll of netting only to within 4ins. of the ground, and to stretch three or four strands of plain wire tightly along the intervening space. This enables one to cut the grass with hook or shears easily, and at the same time effectually keeps the balls within bounds.—R. KEENE, *St. Albans.*

THE BEST WAY TO START LIFTING POTATOES.

SIR,—I commenced lifting potatoes this week and found that the first row I dug wos in a much better condition than the second. The tubers were dry and clean and were much better and bigger than those of the second row, which were wet and sticky. My explanation is that the first row faced east and got more sun than the second. The second row will now get the sun (if any) and that will dry the tubers and help to develop them. So my hint is: Dig one row at a time, commencing with the row facing east, and give each row four to five days "to air" and dry, then dig up No. 2, and so on.—A. J. JOLLIFFE, *Warren Town, Newmarket.*

AN OLD CUSTOM.

SIR,—When Queen Mary was recently visiting the Midlands, she strolled through the famous religious garden at Packwood Hall. In years gone by religious gardens were very popular features of all country houses, and the one at Packwood is a remarkably fine specimen. This represents the Sermon on the Mount and the figures are symbolised by yew trees. One very high tree in the middle is the Mount, four trees near are the four Evangelists, and twelve others are the Apostles. All around on lower ground over a hundred magnificent yews stand for the multitude gathered round. The Queen walked along the corkscrew path leading to the Mount and sat in a tiny summer arbour admiring the well preserved grounds, and expressed her interest in the symbolism.—CHARLES H. LEA, *Birmingham.*

OUR PHOTOGRAPHIC COMPETITION

With this week's issue our competition closes, but the widespread interest it has aroused, both at home and abroad, and the influence it has made have not ended. Amateur and professional gardeners alike have testified to its usefulness, and we think it high praise indeed that those whose business it is to design and lay out gardens have acknowledged that they have gained ideas from the work done by amateurs as illustrated by photographs of their gardens which have been shown in our competition pages. Our hope is that less favourable photographic weather during the coming months will not deter our readers from using their cameras when any work, constructional or otherwise, is being done, as their fellow readers may learn something from such photographs.

This photograph, taken in the gardens at Lavington Park, shows the two blue borders which are on either side of a wide grass walk. Erigerons, campanulas, Nepeta Mussini and Viola Maggie Mott are the chief plants growing there. Lilium candidum and pillar roses form a pleasing background.
The guinea photograph, sent in by A. MAY, *St. Margaret's Bay, Dover.*

The sundial, which marks "only the shining hours," is fixed on a column of granite. A dwarf lavender and a rock rose are planted at its foot, and near it is a bird bath for the robins. The lilies show up well against the dark background of trees.
MRS. CRESWELL, *Ewhurst, Surrey.*
Award of 5s.

This balcony in Whitechapel has been quite transformed. The blue African lily (agapanthus) flourishes in the tubs, and the four sink gardens, which are filled with dainty rock plants, are most attractive. MISS MONK, *London Hospital, Whitechapel, London, E.1.* Award of 5s.

In August a very pretty effect can be obtained by hydrangeas and Agapanthus umbellatus, the latter growing in tubs in front of a veranda. In the winter the agapanthus tubs are put under the veranda (dwarf periwinkle edges the veranda floor). LADY THORNEYCROFT, *Bembridge, Isle of Wight.* Award of 5s.

This summer-house and garden were made in an odd corner. It is now a very pretty and useful spot. In the summer the two side borders are filled with tobacco plants, and during the spring with yellow wallflowers. The centre bed is edged with dwarf box, and planted with catmint on

the outside and salpiglossis in the centre. The salpiglossis, when it has finished flowering, is replaced by orange and blood red wallflowers. Azara microphylla, clematis and escallonias are growing up the walls. E. G. DRINKWATER, *Oxon.* Award of 5s.

A SUMMER-HOUSE WITH A PLEASANT OUTLOOK.

This photograph shows a beautiful garden at Footscray Place, the residence of Lord Waring. The design of the archway is particularly fine. There are borders of herbaceous perennials on either side of the path. These perennials bloom throughout the summer. MRS. HINDMARSH, *Eltham.* Award of 5s.

This lily pond is in the centre of my sunk garden. The pond round the edge is bright with Cambridge blue lobelia and ageratum, and soon the portulaca will be out, making a splash of vivid colour against the stones. MISS REDMAYNE, *Preston.* Award of 5s.

FRUIT AND KITCHEN GARDEN

Planting Out Spring Cabbage.

SEPTEMBER is, no doubt, the best month for planting out the spring cabbage—or Whitsuntide cabbage, as some call it. There is sufficient warmth in the soil for the plants to get a good start and become well established before winter. There should now be plenty of available ground that has been well manured and cultivated for the previous crop, such as shallots, onions or potatoes. Cabbages flourish best in a clay loam, and as they are gross feeders they naturally require plenty of support in order to make large hearts; hence, if the soil is of a sandy or gravelly nature, it will require more fertilising matter. As the main object is to produce a mass of leaf matter, the most important need is the nitrogenous element, which can be conveniently supplied by the application of soot, sulphate of ammonia, guano, fowl manure or sheep droppings, either in the solid state or by means of liquid manure when active growth begins again in the spring. Some people prefer to apply a little nitrate of soda in small dressings during showery weather, as it is a soluble and quick-acting fertiliser. It is very important to keep the ground loose and open around the young plants by constant hoeing and light forking. They readily respond to this treatment. If slugs are troublesome a ring of soot and lime around each plant should suffice. A buttered cabbage leaf acts as a good trap. —G. T.

Ripening Tomatoes.

BOTH indoor and outdoor tomato plants are now making rapid growth, so need close attention as regards the removal of side growths and diseased fruit. The latter should be burnt. There is more to contend with under glass in the nature of insect life. To cope with such pests cleanliness and spraying seem to be the most effectual means. In order to get the full benefit of all sunshine, any leaves shading the fruit should be cut back. This is the time when frequent applications of liquid manure are most beneficial as the plant needs plenty of available food to mature the crop. The soil around each plant should be kept loose and friable. As the plants develop they should be securely tied to stakes or other supports.—S.

The Importance of Protecting Broccoli.

MANY broccoli need protection from frost, particularly those which were not planted on firm soil and on soil that had not been previously manured. Firm ground and a position shielded from the north and east should always be selected. The first is not difficult, as it is within the scope of most, when planning for vegetables, to set apart a plot that has not recently been dug but which has been enriched with manure for a previous crop, as, for instance, spinach, or peas. If planted out in recently dug, loose soil, broccoli will romp away and make huge specimens by late autumn. It is with these "free and easy" growers that trouble mostly arises, as they have little staying power as compared with those got in in firm ground requiring the services of a strong dibber to make a hole for the roots. Such plants nearly always grow stronger and more sturdy, and as a result withstand frost much better than the others.

In a time of frost, it is wise to be prepared with material at hand to afford shelter, but it is unnecessary to afford such help until frost comes, because, after all, broccoli is very hardy, and anything approaching coddling should be avoided. There are, of course, several well known sorts that are almost independent of any kind of help in this direction, except in a time of extended frost, such, for example, as Snow's Winter White, Knight's Protecting or Veitch's Self-Protecting. These will stand several degrees of frost without harm, but even taking that into consideration, it is such an important vegetable that when severe frosts come some provision in addition to their own protecting leaves should be at hand. In some winters, as was the case last, no need was experienced, but it is well to be prepared to afford help if required. One may bring into requisition old pea haulm, straw litter or bracken, pressing this material well around the neck of each plant, and scattering some among the rows. It is not much trouble, but should necessity arise, in a time of hard frost, it is the little help which ensures the crop going through and coming to maturity. Let it be borne in mind, that although the plants themselves are hardy, the flowers or curds feel frost quickly.—C.

Present Treatment of Loganberries.

ALTHOUGH loganberries are strong-growing plants, the new wood was made late in the season this year. Probably the cold, dry spell in spring retarded growth. Fruit trees must be well matured if full crops are to be obtained from them, and it is so in the case of bush fruits, raspberries and loganberries. To secure wood as ripe as possible this year all old fruiting canes should be removed as soon as possible. Perhaps some readers have already attended to the work of pruning. Even if they have, I invite them again to inspect their plants and study them. It may be that more old wood can be with advantage cut out now. Instead of allowing the young canes to lie on, or near to, the soil, tie them up as high as possible, provided they are not unduly crowded, and expose them to the winds as well as the sunshine. If new loganberry trees are to be planted, select positions exposed to the south-east, south or south-west. Some of the heaviest crops I have seen were gathered from plants facing south-east where they had the benefit of the early morning sunshine. It may be because the loganberry will grow in almost any kind of soil that so little preparation of soil is carried out. But it pays to trench the soil thoroughly and add some old mortar rubble to it in districts where the soil is deficient in lime. Allow ample room for each plant to grow. Annual shoots grow 6ft. to 8ft. in length; such specimens require for each one at least 12ft., and not any should be planted nearer together where the shoots are to be trained to the right and left. Isolated plants often succeed well because they have plenty of room in which to grow. Plant in November. —G. G.

On Cooking Vegetables.

THOSE who grow their own vegetables have both the pleasure of seeing them develop and of enjoying them under the best conditions, since when gathered fresh from the garden, and especially in their young and tender stages, the delicate flavour peculiar to each vegetable is most pronounced. It may not be generally known that the French prepare a delicious soup from the entire pods while the peas are very young and tender. Scarlet runner beans cooked whole when very young are far superior to the more matured bean cut in slices, while vegetable marrows have more flavour if cooked whole quite young and tender. Moreover, by removing some of the first growth of these vegetables their period of production is prolonged and better development ensues. The white turnip is another vegetable which is more tasty if cooked very young and fresh. Sowings made now should provide roots to the approach of winter. Both first and second early potatoes are better cooked as soon as they are dug. The less they are exposed to the light the better.—G. S.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints (which should not exceed 150 words in length) is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF-GUINEA HINT

Constructing a Rock Garden.

All rock plants require a free root run and ample drainage. To ensure this, the foundation of a rock garden should consist of stones, brick-ends or anything that will give good drainage; never should it be a bank of heavy earth. The stones that are to show should be near the surface, each being nearly buried when the soil is added. Turves should be placed over the stones wherever there is to be soil, to prevent the crevices being blocked by soil. The compost should be of a free and porous nature; grit or gravel mixed with good light loam and leaf-mould is suitable for nearly all rock plants, but many also require lime rubble. The best time for construction is the autumn or early winter. The soil will then settle during the winter, and planting can be commenced in the spring. —C. O'C.

A Remedy for Coral Spot.

A very simple and yet effective cure for Nectria cinnabarina, better known as the coral spot fungus, on the stem or branch of a tree or shrub, is to slice off the infected part with a knife, cleaning off all the bark right into the wood, and then applying a good coating of tar. Should it appear later round the side of the wound already made, slice off again and tar. A plant of Pterocarya stenoptera, the stem of which was badly infected with the fungus, has been completely cleaned, and the plant is now growing vigorously.—D. A. D.

Dahlias and Earwigs.

At this season of the year earwigs are a real menace to growers of dahlias, chrysanthemums, etc., and to deal with these pests I have found the following treatment to be very effective. First obtain an adhesive gum, such as "Stictite" or anything "tacky." Apply this at base of stems 1ft. from ground; then again at various intervals along the stems and branches. When growing for exhibition it is advisable to cut strips of paper and tie loosely, but securely, around the flower stems at about half way and dress this with the sticky substance. One application will prove sufficient.—W. H. P.

An Excellent Method of Preserving Beech Leaves in Autumn.

Pick when turning brown, and stand in a mixture of one half water and one half glycerine. The mixture need only reach about 6ins. up. When absorbed, the leaves have a perfectly natural appearance and keep for months.—M. H.

WORK IN THE GREENHOUSE

Treatment of Pot-Grown Roses.

ROSES grown in flower-pots are very useful and extremely interesting, but they are not easily managed unless certain attention be given after the flowering season. The flowering period may extend to seven months under expert treatment, but these notes are written mainly for the benefit of the inexperienced.

It is after flowering that the plants suffer if great care is not taken of them. We all know that roses in open borders make a lot of late growth at this season and pot-grown ones will do so also if they are placed on a bed of ashes in an open quarter, kept cool, free from mildew and well watered. This is the time to repot the plants, those that require more rooting-space, and surface mulch others that will do well for another year in their present pots. The compost should be a simple one; it may be possible to reduce the size of the old ball of soil considerably without doing harm to the roots, but no attempt should be made to reduce it if by doing so the roots will be damaged. A plant now growing in a 9in. pot should be shifted to one measuring 11ins. across. This will be a sufficient addition to the rooting space. In cases where top-dressings suffice and repotting is unnecessary, the surface soil should be removed down to the uppermost roots and replaced with compost similar to that used for the repotting, only it may be a little more fibrous. Fibrous loam inclined to be heavy rather than light and cut about six months ago is the best to use. To each bushel add a 5in. potful of bone meal and a similar quantity of wood ashes quite dust-dry. The ashes will be beneficial in helping to produce firm new wood made while the plants are growing under glass. Pot firmly. This is all that need be done now except that in very hot quarters the pots may be plunged to their rims in ashes.—H.

Trapping Cockroaches.

COCKROACHES are often great pests in greenhouses, mushroom beds and wherever else they can find some protection. These creatures will devour anything that can be eaten, and more often than is commonly supposed damage to plants can be traced to their efforts. On account of the fact that the cockroaches get about almost exclusively at night, many gardeners are hardly aware of their presence until, perhaps, they are moving pots or disturbing some things that have remained in one position for a long while. Arsenic and phosphorus are sometimes used for killing cockroaches, but both of these are so poisonous that it is safer to leave them alone, especially as simpler methods of dealing with the pest are just as effective. One plan is to secure a quantity of the common bracken fern. Put fresh fronds of this where cockroaches are known to abound and leave for a night. For some reason the insects are very fond of this fern and will eat it greedily, but they die quite soon after their repast. Here is a cockroach trap which is very good. Half fill a fair-sized basin with water and then mix with this a few spoonfuls of honey or treacle. Place the basin on the floor and then rest three or four sticks so that one edge is on the rim of the bowl and the other on the ground. The cockroaches will clamber up the sticks and fall over into the bowl and get drowned. Another way is to half fill glass jars with a sweet solution and then sink these to the rim in the ground. Many cockroaches will tumble in when they try to get at the sweet liquid, but they will not escape again. Cockroaches are very fond of oatmeal. Scatter some of this on the floor for one or two nights and then finally make a mixture of half oatmeal and half plaster of Paris.

Stimulants for Greenhouse Plants.

AT the present time there are many plants in pots in the greenhouse, and others in frames and out of doors that before long will be brought under glass, which benefit by a judicious use of stimulants. The latter may be procured in a highly concentrated form, and, if the directions on the tin are rigidly followed, one cannot go far wrong in the case of such things as fuchsias, heliotropes, zonals, primulas and cinerarias; but no stimulants should be given until after the customary clear watering. In the hands of a beginner guanos and fertilisers applied according to the printed instructions which accompany them, are often safer to use than are liquid stimulants made from cow, sheep or horse manure.

While robust-growing things like chrysanthemums in pots quartered in the open air, will take a stronger application than less vigorous plants, it may be said even in their case, that it is much better to give two applications in a week, well diluted with water until about the colour of weak tea, than to over-dose them with strong food. The use of stimulants in moderation is very helpful to plants in pots just now, but it may be overdone in one's anxiety to have a plant in flower by a given date. That cheap and easily obtained stimulant—soot—is one which is both safe and useful if it is put in a coarse bag (after the fire has gone out of it by exposure to the air and turning it over now and then) and placed in a water tub. It is one of the best home stimulants for promoting healthy green foliage, and, generally speaking, adds vigour to a plant.—C.

How to Grow Early-Flowering Gladioli in Pots.

THE early gladioli are very suitable for growing in pots for the decoration of the cold greenhouse. They flower in April and May at a time when the spring bulbs are over, and on this account prove extremely useful. To get the best results the bulbs should be potted in October. Place three to six bulbs, according to size, in 5in. or 6in. pots. Any good quality garden soil will answer the purpose, although if this is very heavy it may be made lighter by the addition of sand. Plunge the pots to the rim in ashes in a cold frame, or choose a sheltered position out of doors. Note that the pots should stand on ashes, or some firm base, through which worms are not likely to work up. When the growths are pushing up freely, move the plants to a shelf or other light position in a greenhouse or simply leave them in the cold frame until the first flowers are ready to expand. Protection from severe frost must be given or damage will result. There are a number of fine sorts of these early-flowering gladioli and, when ordering, it is worth while securing as big a selection as possible. Note that the bulbs of these forms are very much smaller than those of the gladioli which flower in the autumn. All the undermentioned are recommended as being sure to please. The Bride, with pure white flowers, which are very freely produced; Blushing Bride, white flowers marked with crimson; Suttons Queen of Pinks, which is probably the finest of early flowering gladioli yet sent out. The long spikes are closely set with large well expended flowers of a delightful shade of salmon pink. Ackermani, salmon coloured flowers with white blotches, shaded red; Fiery Knight, large bright vermilion scarlet flowers on long spikes; General Scot, soft pink blooms with cream and scarlet blotches; Spitfire, brilliant scarlet flowers with crimson blotches and very free-flowering. Where it is not specially desired to grow named forms, it may be pointed out that the mixed bulbs offered by the leading firms are very good value indeed.—S. L.

Some Acacias for the Cool Greenhouse.

OWNERS of cool greenhouses hardly give sufficient attention to the Australian acacias, which are of considerable decorative value and are not at all difficult to grow. These plants are quite happy in a house where they can just be given protection from frost, although the time of flowering will be advanced if a little artificial heat is available. The blossoms are mostly some shade of yellow and these are produced in globular heads and cylindrical spikes, each containing many flowers. The leaves are very variable in the different species and, although the pinnate or feather-like leaf is the most common, there is a section in which flattened leaf-stalks function as leaves. The most suitable soil for acacias is a rich compost formed of equal parts of loam, leaf-soil or peat, to which a little charcoal has been added. Thorough drainage is essential and repotting must be carried out with care at the right time. After the flowering season the branches are cut back moderately hard and the plants are then kept rather close and moist for a few weeks. As soon as the young shoots start to grow vigorously repotting may take place. In most cases acacias will do quite well if left undisturbed for several years. During the summer a sunny position out of doors is best and, in dry weather, careful attention must be paid to watering. Propagation of these acacias is carried out by means of cuttings of the tips of the half-ripened wood taken in summer and placed in very sandy soil under a bell glass in a cold frame. A few of the acacias of more tender habit will require more heat to ensure a rooting of the cuttings. The plants are not difficult to raise from seed and these should be sown about 3ins. deep in sandy soil. Good kinds of acacia for growing in the cool greenhouse are A. armata and its variety angustifolia, A. hastulata, A. leprosa and A. riceana.—S. L.

Annuals for Autumn Sowing.

ON account of brilliant results, general utility and simplicity of culture, both in the greenhouse and in the garden, annual flowers are extremely popular in every quarter. Among the best for greenhouse cultivation are the various types of clarkia, salpiglossis, viscaria, nigella, calendula, nicotianas, mignonette, sweet peas, godetia and others, sowings of which, as detailed below, may be made just now in order that bright bloom and sweet scents may fill the greenhouse in spring. In the open there is wider choice and, provided that the soil be a porous one and the winter at least reasonable, an early show of blossom can be ensured by getting the seed in at once. The list again includes the clarkias, limnanthes, saponaria, nemophilas, candytufts, silenes, bartonia, calendula, annual chrysanthemum, Virginian stock, nigella and others. When the plants are to be grown in pots, sow seed in small sizes (3in. or 4in.), a pinch in each, the compost being loam with a little sifted leaf-mould and sand. Just cover the seed with a sifting of fine soil and germinate in the usual way in a cold frame. Ventilate freely after the seedlings come through, and, late in October, when the pots are taken inside, let them stand on a shelf near the glass. Thin the seedlings out to three or four, and avoid over-dampness. Pot them on later into 6in. pots. In the open, sow in drills 9ins. apart, in firm, unmanured but good soil; sow thinly, but thin out later in order that the plants may stand apart and be robust.—A.

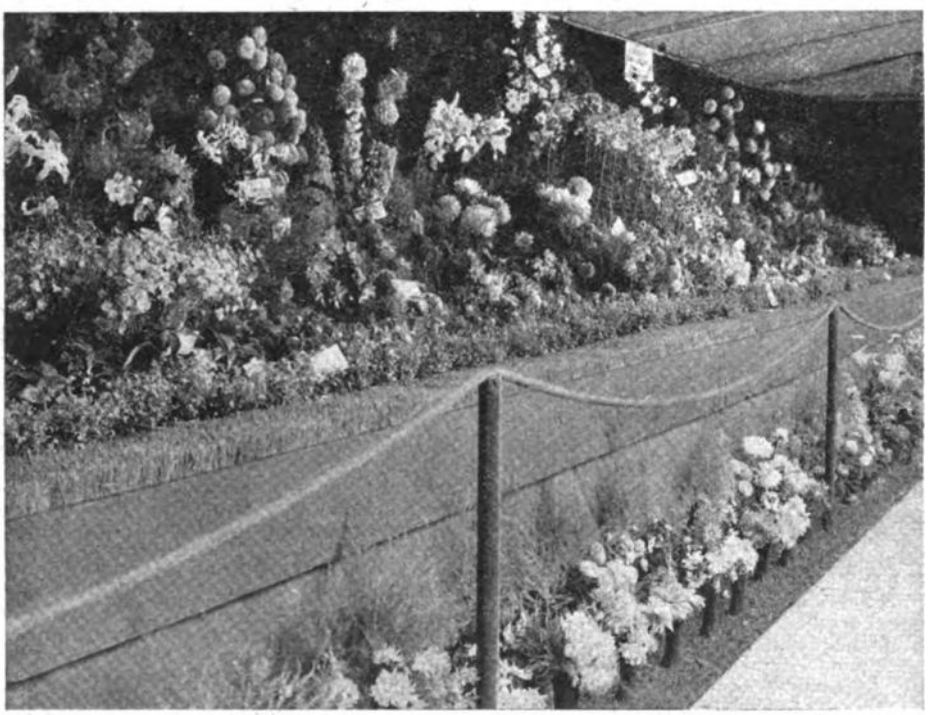
TEMPLE GARDENS SHOW

WALK down any market street in London and watch how eagerly the Londoner buys flowers and plants. There is no doubt about his love of flowers and his genuine desire to grow them for himself. Thousands and thousands of seedlings must be sold to London's amateurs each year. Cherished in their gardens month after month, they eventually find their way to the show tables of the district horticultural societies, to win for their cultivators the admiration of their fellows. On September 3rd–5th amateurs of Greater London excelled themselves at the Temple Gardens Exhibition, organised by the London Gardens Guild. The arrangement of the Show was unique. Instead of the usual stuffy tents, the marquees were constructed as half-span structures open on one side. By making the marquees face each other the effect of an avenue of flowers was produced. Down the centre a number of model gardens were arranged. The first was a water garden, constructed by Mr. Amos Perry of Enfield. Farther down, a fine display of clematis and other flowering and fruiting shrubs was staged by Messrs. L. R. Russell of Richmond.



A FINE EXHIBIT STAGED BY THE BERMONDSEY BOROUGH COUNCIL.
This exhibit shows what can be grown even in a smoky district such as Bermondsey.

Twice as Big as Last Year.

A break in the avenue at this point led to a large open square of velvety grass, the sides of which were also filled with London-grown flowers. This part of the exhibition was a new feature and made the whole Show fully twice the size it was last season. In the far corner were staged displays from the prize-winning gardens in the recent All-London Gardens Championships. The gold medal awarded for the best of these displays was won by Mr. Charles H. Dyke, Thornton Heath, whose flowers and foliage plants showed an extremely high standard of cultivation. Many unusual specimens were included in his display.

It was interesting to compare this class with the displays from other entrants in the Garden Championships, and it was evident that even in gardens where no special award was given by the visiting judges, there were, nevertheless, many well grown plants.

Mr. C. Campbell of Charlton won the gold medal among the displays from non-prize winning gardens.

Corporate Displays from Local Societies.

The owners of small gardens are often disappointed because at Show time they have not sufficient flowers in bloom to make a large display. If they belong to a local garden society, however, they are often able to contribute a few fine blooms to a corporate display staged in the name of the society. Many hundreds of London gardeners must have contributed their quota to the corporate displays staged at the Temple Gardens. These showed an exceptionally high standard of cultivation, the best display in the eyes of the judges being that staged by the Mount Pleasant G.P.O. Society. Among local societies, apart from the P.O. horticultural societies, the best display was made by the Camberwell Gardens Guild.

Trade Exhibits.

One of the most attractive features of the Show was undoubtedly the replica of the Championship Back Garden in the recent competition, which was made by Messrs. James Carter and Co. of Raynes Park. There were also model gardens on view, made by the proprietors of "Noelite" (Messrs. A. J. Redgrove and Son of Borough Green) and by the Rhymney Quarries, Limited.

Other exhibits by the trade included roses, by Messrs. R. Neal and Sons, Wandsworth; and Benj. R. Cant and Sons, Colchester; hardy plants, by Messrs. Lowe and Gibson, Crawley Down; Castle Nurseries, Limited, Chingford; and R. J. Case, Taunton; anemones, by Messrs. Reamsbottom and Co., Middlesex; gladioli, by Messrs. W. J. Unwin, Histon, Cambs; and A. Dawkins, Chelsea; bulb display, by Messrs. J. Carter, Raynes Park; herbaceous plants and roses, by Messrs. Wilson and Agar, Reading; carnations, by Messrs. Allwood Brothers, Hayward's Heath, and Messrs. C. Engelmann, Limited, Saffron Walden; hardy plants and clematis, by Messrs. H. J. Jones, Hither Green Lane; floral decorations by Messrs. Shearns, Tottenham Court Road; montbretia, by Messrs. Daniels Brothers; and garden designs, by Mrs. Marjory Allen. Arches and garden furniture made by the Castle Shipbreaking Company were also on view.

Individual Classes.

Among the individual classes, one of the most interesting was the Class 4, three spikes of gladioli. In this case a gold medal was awarded to Mr. S. H. Gregg of Wood Green, for a vase showing one spike of Flora and two new seedling gladioli, one of which was named after the *Daily Express* and one "Richard Sudell," as a compliment to the Organising Secretary of the Guild. The latter was a particularly charming flower of pale pink with a deeper pink edging.

Three of the individual classes were reserved for exhibitors resident within five miles of London Bridge. Mr. Butcher of Bermondsey, Mr. Oxer of Clapham and Mr. Baker of Dalston won the gold medal in these three classes. These classes alone were sufficient indication that the difficulties of the London atmosphere are not insurmountable, but that, given the desire, fine blooms can be grown in any district.

The Daily Express *Challenge Trophy.*

A challenge shield was offered by the *Daily Express* to the society whose members ecured the greatest aggregate of points in the Exhibition. This challenge shield was won easily by the Charlton and District Horticultural Society, whose number of points totalled 100; the runner-up was the Bermondsey Gardens Guild, with 68 points.

One of the outstanding features was the corporate display of flowers by municipal authorities, Bermondsey's exhibit, staged by the Park Superintendent, Mr. W. H. Johns, N.D.H., being awarded a gold medal. There was also a Ministry of Agriculture Information Bureau, which answered enquiries and gave advice on plant diseases and pests. Experts were in attendance at the Gardens Guild Tent who gave advice regarding problems of town gardening. The band of the Honourable Artillery Company played each day.

The Exhibition was an enormous success from every point of view. Between the time that the Show was opened by Lord Lambourne the President of the Horticultural Society, at 2.30 p.m. on Saturday, and Monday evening, when the awards were distributed by the Editor of the *Daily Express* and Mr. E. Cruse, Deputy-Chairman of the London County Council, between 20,000 and 30,000 people visited the Exhibition.

SOCIETY NOTES

Paisley Florists' Society.

INCREASED interest was taken in the annual two days' autumn show of this Society, which was accommodated for the first time in the more commodious premises of the Clark Town Hall. The change was the means of attracting a greater number of entries, and both from a competitive and exhibitive point of view the exhibition was one of the most successful ever held.

While the open section was poorly represented, it contained a number of high-class exhibits, particularly the classes for thirty-six blooms of roses and six vases of decorative roses, with which Mr. William Ferguson, Dunfermline, secured the chief honours.

Major Brown, Westerlea, was the most successful competitior in the plant and cut flower division. He won first prize in thirteen classes, and was particularly strong in chrysanthemums and dahlias. Mr. T. Harvie and Mr. D. Graham shared in the honours awarded to pot plants, while Mr. A. Carmichael excelled in sweet peas and annuals.

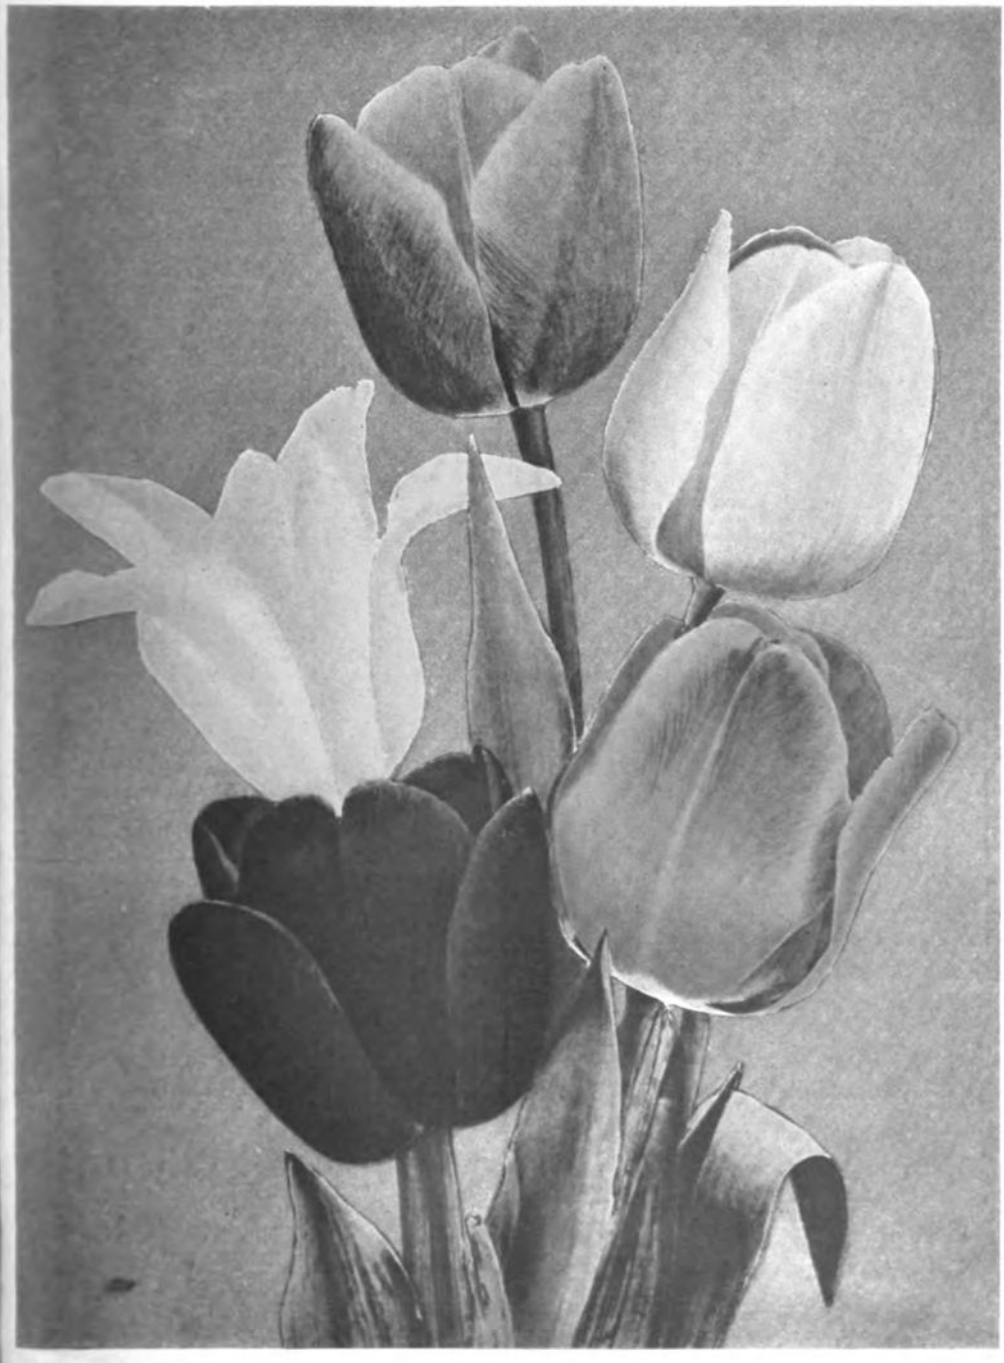
THE GARDEN

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2912 Saturday, September 24th, 1927 Price TWOPENCE



Ryders

BULBS

Some Glorious Varieties

RYDERS Bulb Book for the new season is now ready for distribution, and all gardeners who have not yet received a copy should send at once a Post Card Application giving their name and address.

Ryders sell more bulbs than any other retail house and are thus able to secure the pick of the bulb fields at prices which enable them to bring the joy of bulb growing within the reach of everyone.

Bulb lovers will find the new Ryder Bulb Book of exceptional interest and practical worth. Included among the host of more established favourites for indoor and outdoor growing will be found lists of some exceptionally beautiful novelties. Particular mention must be made of THE BULBS ILLUSTRATED IN COLOUR ON THIS PAGE: MRS. MOON (Cat. No. 704) one of the most glorious of Ryders May-Flowering Tulips. This scented Tulip is a grand pure yellow with beautifully reflexed petals. Other outstanding Tulips will be found among the DARWIN Series, and include CLARA BUTT (552) a soft pink ringed salmon; the famous Black Tulip LA TULIPE NOIRE (588) a very dark maroon black; PRIDE OF HAARLEM (620) a brilliant rose carmine with blue base, and REV. H. EWBANK (628) a soft lavender violet.

SPECIAL NOTE

Immediate delivery can be given, of all **Bulbs.**

SEND FOR BULB CATALOGUE NOW

Ryders desire to state that all bulbs in their catalogue are of the first quality only and thus have a **reserve of energy** which will enable them to give good returns under conditions which would spell failure to the many second-rate bulbs so largely advertised from Holland, and **against which the Dutch Government issues a special warning.**

Secure your Ryder Catalogue at once and you will incur no risk of failure. Simply send a Post Card with your name and address and the catalogue will be posted by return.

WINDBREAKS IN SMALL GARDENS

DURING the past few years the influence of wind on plant growth has been the subject of considerable study, particularly in public gardens and in some of the larger private gardens. Apart from such obvious damage as the wearing action of wind on the taller plants in the herbaceous border, it has been proved that frost, accompanied by air movement—what might be called draughts—causes more damage than a low temperature on still nights on young growth in spring, especially of trees and shrubs. This has brought about the use of both permanent and portable windbreaks. Naturally, in the more confined area of a small garden, often divided from the garden next door by a paling that acts as a windbreak, such appliances for keeping off wind are not such a necessity; nevertheless, they have their uses, and the cultivator of even the smallest garden should not neglect to consider the action of wind on his plants. Such advice would have been particularly applicable earlier this year, owing to the peculiarities of the past summer. As a rule, the prevailing wind during the summer months blows from the west, and gardeners with any experience usually take this into consideration when preparing their planting plan. This summer there has been an unusual amount of fairly strong easterly winds, with the consequence that many of the taller herbaceous plants protected from a westerly wind have suffered wind damage from which no amount of staking has saved them. This is an occasion when a portable windbreak would have been of considerable assistance.

These portable windbreaks can be made of the lightest materials, as it is surprising how little is necessary to break the force of the wind. Hurdles are excellent for this purpose; they are light, inexpensive and easily moved. Or even more simple is sacking, hessian or mats, such as are used for shading frames, tied to a few stakes and stretched in position when the wind blows strongly. These can be rolled up when not in use or put to other uses. Even a few branches firmly anchored in the ground, will be the saving of much wind damage.

Useful though these portable shelters are, owners of all gardens, particularly new ones in exposed positions, should try to provide permanent windbreaks on the sides from which prevailing winds blow. Only too often does one see excellent attempts at new herbaceous borders ruined by exposure to a prevailing wind. The experienced gardener will make it one of the first jobs in a new garden to see that he combats the prevailing wind at the earliest possible moment. A row of evergreens is useful, but in this case kinds should be chosen, such as Cupressus Lawsoniana or C. macrocarpa, that are clothed to the foot. Perhaps the most practical windbreak in a small garden is a paling which can be used for growing cordon fruit or climbers and takes up little space. But such solid windbreaks are not necessary. A trellis will give sufficient protection and will give a wall of colour when clothed with climbing roses or clematis, or an espalier for fruit.

In any case, we should like to impress on those who are gardening in exposed positions, the value of windbreaks. Not only do they save a large amount of wind damage during the course of the year, but they lessen the amount of staking during the summer months. There are very few garden plants that do not hate wind, and the latter is a mixed blessing which is very prevalent in these islands of ours.

Early Planting.

AFTER a succession of mild open winters, gardeners have got into the habit of putting off their autumn planting later and later each year. A hard winter is long overdue, and, although it may not occur this year, there is every sign that this is going to be an early autumn. Gardeners who may not have experienced a hard winter, or may have forgotten its effects, should take time by the forelock and see that new additions to their garden are bedded down snugly on the chance that hard weather sets in. It cannot be expected that a plant that is set in its place only a few days before a hard frost will flourish next year as well as one that is thoroughly settled and at home weeks before the frost starts. So early planting is advisable. These past open winters have made us forget that there is such a thing as making a garden snug for the winter. There has only been an occasional day during the past few seasons when active work in the garden has been impossible. Considerable work has been started and left unfinished overnight under the idea of open weather the next day, the next week, the next month. Such a state of affairs cannot continue indefinitely, and it may be that the overdue hard weather may come this winter. In the hopes that this may be the case—and it would do a world of good—gardeners would do well to get their plants in early; it may save losses that need not occur; in any case, the plants will be at home before the frosts commence. This may be a counsel of perfection, but it may be necessary. Therefore, plant early.

This Week's Work

For Gardens in the South and Midlands.

Remove seedling cinerarias and primulas into the greenhouse.
Plant daffodils, hyacinths and Spanish irises in beds and borders.
Lift and store potatoes, onions, beetroot and carrots.
Clear up strawberry and asparagus beds.
Take cuttings of calceolarias, violas, geraniums, pentstemons and antirrhinums.
Plant delphiniums, bearded irises and peonies.
Dress lawns with worm killer and complete fertilisers and make new lawns by sowing seed and laying turf.
Trim evergreen hedges and box edgings.

This Week's Work

For Gardens in Scotland and the North.

Lift any potatoes that still remain in the ground.
Prepare ground for new raspberry beds.
Burn haulm of garden peas that have finished cropping.
Earth up Brussels sprouts as a protection against wind.
Plant Spanish and Dutch iris.
Take cuttings of rambler roses.
Finish autumn sowing of sweet peas.
Cut marrows before they become large and tough.
Begin boxing seed potatoes.
Pot daffodils and hyacinths for succession of bloom.
Give greens and lawns a final cutting.
Remove and store dahlia roots as foliage withers.

TULIPS FOR THE AMATEUR

THE best time for planting tulips in the open is October. Our old friend the Rev. Joseph Jacob used to say November, quoting Lord Mayor's Day as the ideal time. This may be the case where one has to deal with a nice, warm, well drained soil; but I am sure that, where the soil is retentive of moisture, the earlier date is far better. For one thing, there is much more chance of finding the ground in a workable condition in October that there would be in November, and if any number of bulbs have to be planted the work will go more pleasantly and rapidly. Tulips like plenty of manure (not in a raw state), but it is not good for the bulbs to come in contact with it. So either partly decayed stuff should be used or, failing that, dig in some raw bone-meal—3 oz. per square yard—at time of planting, and give a light top-dressing of stable manure during the late autumn or winter. Peat moss litter manure is the best; it is easily spread, and does not look unsightly.

Some of the very best tulips for bedding—*i.e.*, the early Dutch varieties—are Augusta, deep rose pink; Couleur Cardinal, brilliant crimson shot with purple; Dusart, crimson scarlet; King's Crown, bright crimson edged yellow, a large flower and very showy; Lady Boreel, large pure white; McKinley, orange red, shaded carmine, distinct; Mon Tresor, very fine yellow; Prince of Austria, bright orange scarlet, sweetly scented, one of the very best early tulips for either bedding or pots; Vermilion Brilliant, extra good, early, also fine for pots; Van der Neer, violet purple, very large, and lasts well.

Doubles.—Boule de Neige, one of the best whites; Murillo, beautiful blush, alike good for beds or pot work; Rubra maxima, dazzling crimson scarlet; Safrano (Tea Rose) Primrose, yellow flushed salmon.

Late or May Flowering Tulips.

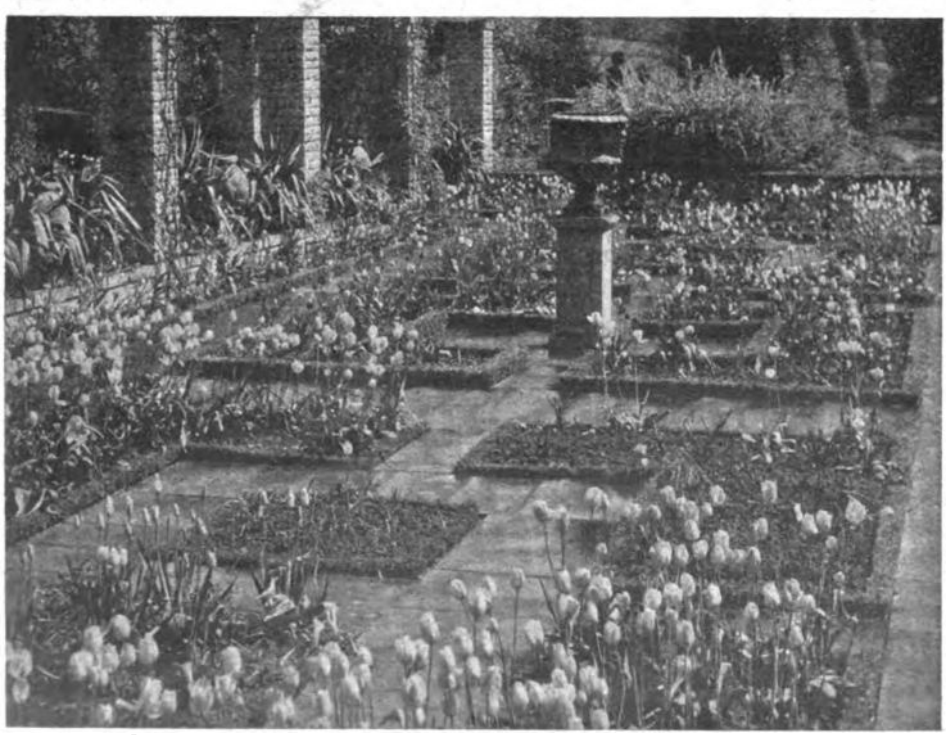
These may roughly be divided into two sections: the cottage, and Darwins. Some of the cottage varieties might well be taken for Darwins, but a committee of experts has placed them in the sections to which they believed them to belong, and a classified list was issued by the R.H.S., so the public must now accept this order of things until a revision of the list takes place. There are quite as good things among the "cottagers" as there are among the Darwins, and all are very suitable for cutting, having long stalks. Some of the very best are: Bouton d'Or — as its name implies—a buttercup yellow, with medium sized, cup-shaped flower, may be planted among Darwins, as it flowers at the same time and is the same shape; Gesneriana major, deep crimson, with indigo blue base, a most gorgeous tulip, but a little bit tender; Inglescombe Pink, a kind of buff pink on opening, turning pink with age; Inglescombe Yellow, a well formed flower, very late; La Merveille, salmon, shot with vermilion, very sweetly scented; Mrs. Moon deep yellow flower of graceful shape, very tall, late; Orange King, very sweet; Picotee, white with carmine edge to petals, very good for cutting.

COULEUR CARDINAL, ONE OF THE BEST EARLY SINGLE TULIPS FOR BEDDING PURPOSES.

Darwins.

These are all tall and stately; they have a wide range of colours, though no yellows are allowed to be classified under the heading of "Darwins." There is an enormous number of these tulips on the market; no two catalogues contain the same varieties, and new things are constantly making their appearance.

Space will not allow of my naming those which are of outstanding merit, and which are reasonable in price. There are very few amateurs who are ready to give high prices for new tulips, and, unless they are able to cultivate them and increase them, it would not be wise to give as much for one bulb of a novelty as would buy ten to twenty bulbs of one of the older things: Bartigon, rich deep red, strong grower; Clara Butt, pale rose pink, a very popular variety; Edmée, deep rose, edged pale pink—there are at least six Darwins on same lines as Edmée, but I think it is the best; Farncombe Sanders, vivid cherry red (I always say that if confined to one tulip this would be my choice); Feu Brilliant, one of the very best bright reds; La Tulipe Noire, as nearly black as any flower which has yet been produced; Marconi, deep purple, a huge flower, the finest of this colour; Margaret, flower of pale pink, resembles a bit of delicate egg-shell china—late; Petrus Hondius, deep rich rose, very distinct; Pride of Haarlem, one of the very largest and very best, deep brilliant carmine, one of the first to bloom; Prince of the Netherlands, deep cherry red, very large; Rev. Ewbank, silvery mauve, about the best in this colour; Valentine, bright violet, large, tall and early; Faust, one of the best of the dark-coloured flowers, tall and stately.



TULIPS ALWAYS LOOK WELL IN A FORMAL GARDEN.

Digitized by Google

Many of the Darwins are good for forcing, though they do not seem to have been much used in this way by amateurs. Having such long stalks, they need carefully staking before fully in flower.

A few well grown pots of Darwins placed on the floor of a conservatory among foliage plants would have a very telling effect. Few if any of the cottage tulips are really good for pot work; when grown under glass they are somewhat weak and floppy.

Those amateurs who have not yet studied their catalogues will be pleased to hear that Darwin and cottage tulips are cheaper this season than they have been for many years. At present figures they are very good value for the money expended, as they make a glorious show in the garden and, given decent weather, they last a long time in bloom.

J. DUNCAN PEARSON.

RHODODENDRONS FOR PRESENT PLANTING

These are among the best flowering shrubs that the amateur can plant in his garden. They are decorative in foliage as well as in flower, and will succeed in almost any garden where the soil conditions are to their liking.

RHODODENDRONS have become more prominent in recent years among the leading gardeners of the country, and it is well from time to time to consider the best way of taking advantage of the varieties which, after thorough testing, can be safely recommended as suited to the requirements of gardens not possessing the ideal conditions for growing the more delicate forms, which in many cases may be said to be the most beautiful. I refer particularly to the Himalayan and Chinese species and the beautiful hybrids which have been raised, for the most part, in Cornwall or some equally mild climate to be found near the sea coast anywhere on the western side of the British Isles where the influence of the Gulf Stream is most felt. It is admitted that these plants are not hardy in the sense that if planted under conditions more remote from the sea influence and less favourable in regard to the selection of actual position, they will suffer from frost, in most cases enough to make them of no use in such gardens, and in some will actually be killed outright. There is, however, no reason to prevent the enjoyment of fine hybrid rhododendrons of a hardy strain. Indeed, so hardy are some, that I have personal knowledge of them coming through American winters—in Massachusetts, for example, where it is no uncommon thing to register 15° below zero Fahr. Such being the case, it is possible, wherever soil conditions allow, to select rhododendrons perfectly able to withstand any weather we are likely to have in the British Isles. It is not as a rule, however, that the most severe winters do the most harm to vegetation generally; but a very early frost in autumn or a very late one in spring will punish anything that, in the first case, is still in a growing condition, or, in the second case, is well on with precocious growth and in a sappy condition. One can select a considerable number of fine hybrid rhododendrons that can be called hardy enough to stand without protection and without injury eight out of ten years. The other two years may bring such a frost as was experienced here last April, when from 15° to 20° of frost were reported in many places within twenty miles of London, and so severe was it that few plants escaped injury. Most of them now show no signs of it and are completely recovered.

Nowadays the enjoyment of the garden is universal. I have noted in the last few years how small gardens have improved, not only in the care that is bestowed upon them and the lay-out, but more especially in the choice of varieties of plants and flowers used. There is still room, however, for improvement in the choice of rhododendrons. There are too many of common things, such as Rh. ponticum or Cunningham's White, occupying spaces which could grow equally a choice hybrid, such as Cynthia, Pink Pearl or any really good hardy hybrid. Once these are seen in comparison with their inferior brethren, and it is realised that they are just as easy to grow, then this particular family will be started on a new lease of life. At present, I fear, the grower is too often satisfied with what is, so to speak, pushed upon him. There are few places where common rhododendrons grow that are not suited to some of the good hybrids. The latter have also one very useful asset—they thrive in an atmosphere which is unfriendly to many evergreens, and in our manufacturing districts—such as Manchester, Sheffield and Birmingham—one finds rhododendrons, not, perhaps, in the heart of the city, but well within smoky areas, growing well and flowering beautifully. Not five miles from the centre of Manchester could be seen, a few years back, flowers of Pink Pearl and Cynthia not to be beaten in

PINK PEARL, A HARDY AND BEAUTIFUL HYBRID RHODODENDRON.

quality anywhere. Plants which will do this under what are not ideal conditions command respect, and are, without doubt, of great value to garden lovers whose means or business keep them in restricted areas near the big towns and, consequently, with a limited space and a contaminated atmosphere. Beyond this immense class of gardeners are those who live in the country in small houses and not very large gardens. The gardens are often made out of a bare field and are without shelter from the four winds of Heaven. These demand hardy plants, and, particularly in the Midlands and northern counties, hardiness is a necessity.

Further points which should be considered are foliage, habit and freedom in producing flower, and a list is appended to this article of twenty-four of the hybrids of hardy type that can be safely recommended for planting anywhere that has the proper soil in which they may grow. It used to be said that peat was necessary; long experience has shown me that rhododendrons will grow well and flower magnificently in soils entirely free from peat. A good turfy loam with plenty of fibre in it is admirable. Lime in any form is one thing that makes rhododendrons impossible. Rank clay without any fibre is nearly hopeless. Clay must be excavated to a depth of at least 20ins., drainage provided, and the soil made up with leaf-mould and turfy top spit well broken up and some 15 per cent. of sharp sand worked into the mixture. Where good loam is found, deep trenching and the addition of some leaf-soil will be found sufficient. On soils friendly to rhododendrons the ground should be always well broken up and the fibrous part of it used round the roots. A mulching of leaf-mould and cow-manure will be found beneficial, particularly in producing good colour to foliage. Care must be taken not to over-feed, as this may induce too much growth, with a consequent lessening of flower.

Now that a new Rhododendron Association has been formed, it is hoped that, in the near future, all sorts of information concerning this wonderful race of plants, not only as to the species but of hybrids of all classes, will be distributed to members. It is also hoped that amateurs, down to those with even the smallest gardens, who are lovers of rhododendrons will in due course take advantage of the Association and join it.

The following list of hybrids is not intended to be in any way exhaustive, but is intended as a groundwork of really good reliable plants with which one is reasonably sure to get a good show each season:

Blush and White Varieties.—Gomer Waterer, The Bride, F. B. Hayes (heavily spotted), Mum (very late), Mme. Carvalho, Boule de Neige.

Red and Crimson.—Bagshot Ruby, Doncaster, Michael Waterer, Cynthia, Fred Waterer, Charlie Waterer.

Pink.—Pink Pearl, Concessum, Mrs. W. Agnew, Philip Waterer, Corona, Mrs. Holford, Mrs. Tritton, Prince of Wales.

Lilac and Purple.—Fastuosum flore pleno, Joseph Whitworth, Everestianum, Purpureum elegans.

F. GOMER WATERER.

THIS WEEK IN THE FLOWER GARDEN

A Good Evergreen Shrub.

Berberidopsis corallina.

THIS handsome evergreen shrub is particularly pleasing when clothing a grey stone wall; in such environment the terminal, drooping racemes of small crimson flowers and the toothed or slightly serrated dark green leaves are seen to great advantage.

B. corallina proves hardy in any but very cold districts and responds to the favourable conditions engendered by a south or south-west wall; a good ordinary compost, loam and leaf-soil, well drained, are necessary.

The generic and specific names are very apt (from *Berberis*, the barberry, and *opsis*, like=resembling the barberry; and *corallina*, coral red), and a well grown example of the plant on a wall or draping the arch of a garden building is both pretty and striking during its season.

Propagation may be effected by layering, in autumn; by seeds, or by young cuttings, in spring.

B. corallina was introduced from Chili in 1862.—R. E. A.

Shrubby Calceolarias.

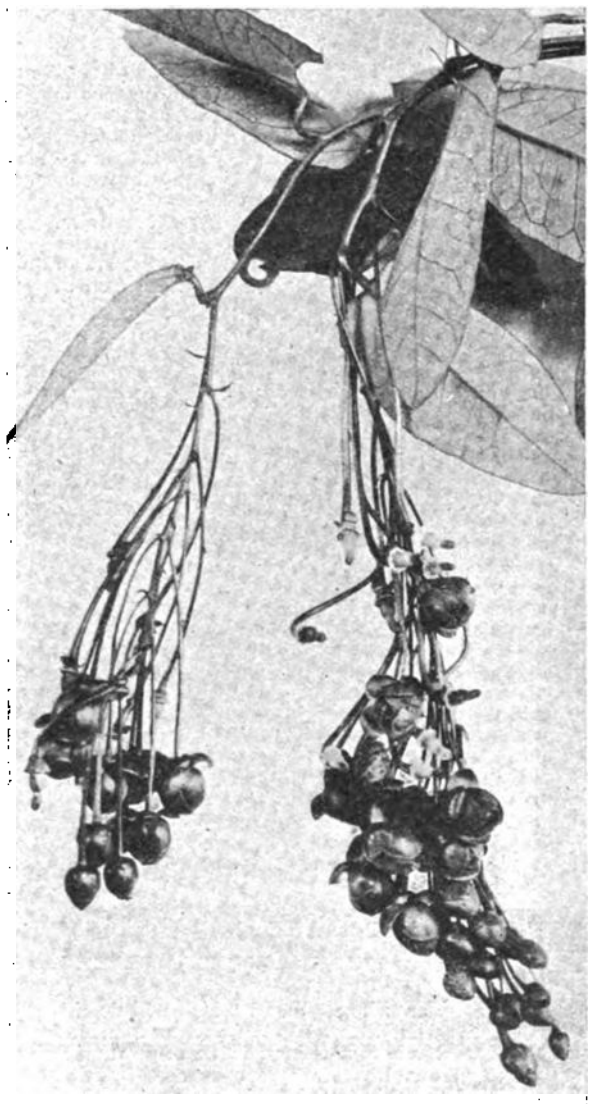
Take Cuttings this Month.

THE shrubby or bedding calceolaria is a very easy plant to grow, seeing that it needs only the protection of a cold frame, hand light or bell glass during the winter. The commonest method of propagation is by means of cuttings, which are taken during September and inserted in a prepared bed of well drained sandy soil. Make the cuttings about 2ins. long and put them 2½ins. apart. A small number of cuttings may be covered with a hand light; but, where the cuttings are numerous, it is best to prepare a bed in a cold frame. Keep the frames closed for a few weeks until the cuttings are rooted, and then give abundance of air. Free ventilation should be allowed all through the winter except when the weather is very cold. During severe frost protect with mats or light dry litter. The young plants will not grow much during the winter, but, as soon as the spring comes, they will start vigorous development. Take out the tips of the shoots once or twice, and, early in April, plant out on a sheltered border where a little protection can be given in the event of a very cold night. By the first week in May the plants will be ready for removal to their flowering positions. All the shrubby calceolarias do best in a soil which is somewhat on the heavy side, and they do not like very hot, sunny situations.

There are many named sorts of shrubby calceolarias, but the following are among the best: Amplexicaulis, lemon yellow; angustifolia, golden yellow; Bijou, bronzy crimson; Camden Hero, crimson; Cloth of Gold, deep yellow; Golden Gem, golden yellow; Kayi, deep yellow; Prince of Wales, crimson; Prince of Orange, bronze yellow; Sultan, dark crimson.

Two very fine and useful tall calceolarias are Burbidgei and integrifolia. The first-named must be given the shelter of a greenhouse during the winter, but it is worth some care, as it will grow to 6ft. or more in height and is in all ways a splendid subject for the border during the summer, and, when taken indoors, will continue to produce its yellow flowers for a good part of the winter.

C. integrifolia will stand out of doors in the winter, in warm, sunny corners, in the south and west of England, and it will also grow at coast localities over a wide area. This species, which also has yellow flowers, grows to a considerable height, but comparatively small specimens flower freely. Both of these species are raised from cuttings taken in September, which may be rooted without any difficulty.



THE DROOPING CRIMSON CLUSTERS OF THE CORAL PLANT (BERBERIDOPSIS CORALLINA).

Plants for Steps.

OF course, only plants of very humble growth are suitable for planting on the treads of steps. One of the best subjects for the purpose is thyme (Thymus Serphyllum). This plant will grow in the driest positions, and it bears treading on; after a little bruising in this way the foliage gives out its delicious fragrance in a very pleasing manner. There are several varieties of thyme, of which the following are specially worth growing on steps: T. Serphyllum alba (a white-flowered form of the common type), coccinea, lanuginosa, carnosus and villosus. The variegated form of the lemon-scented thyme (T. citriodorus) is a lovely plant, although, being of rather a robust growth, it is hardly suitable for placing in positions where it would be trodden on to any great extent. The minute creeping and peppermint-scented T. corsicus with flowers so small as to be almost invisible, is a species which would be perfectly happy in garden steps. Other suitable subjects for such position are Arenaria balearica, Mentha Requieni, Hypericum repens, Potentilla ambigua, Dryas octopetala, Alyssum montanum and Artemisia.

Plants of rather more erect habit, admirable for placing immediately beneath the lower courses of steps, include Erinus alpinus and albus, Campanulas pusilla and alba, Dianthus cæsius, Hypericum coris, Asperulas hirta and suberosa, Hutchinsia alpina, and a number of saxifrages like oppositifolia, Aizoon, Rhei, hypnoides and any varieties of these. Plants are best established in garden steps in the spring and, after setting, they should be watered morning and evening unless the weather is very cold. At this time of the year a good way of establishing any of the plants named is to mix a little of the seed into the joints. The resulting specimens settle into the situations well and will flower in the following year. Just a few plants suitable for these special positions will flower in the same season if seed is sown in the spring. Of these one may mention Linaria alpina, which forms dense silvery tufts covered with bluish violet flowers: this charming little species is usually biennial, but when it is thoroughly happy it often develops perennial habits. In any case the matter is not of great importance, for L. alpina sows itself with great freedom. Sedum cæruleum, an interesting little stone-crop, and Calceolaria mexicana and Saxifraga granulata are also worth growing.

A Good Rockery Plant.

Silene maritima.

THIS native silene of our sea coasts is hardly sufficiently appreciated by rock gardeners, perhaps because it is a home production.

It has blue-green foliage and double white flowers, in size and appearance almost exactly like a Mrs. Sinkins pink. Lying flat upon the ground, it makes an excellent icurtain for a rock face, if it is planted above it and allowed to trail downwards. The plant will soon be quite a yard across. Flowering at the same time as purple or blue aubretia, although for much longer, it is very effective combined with it. This silene does not demand, but much appreciates, a sandy soil. It is easily increased by cuttings taken at the present time, or by division of the roots in spring. Cuttings of half-ripened shoots inserted in sandy soil in a frame or under a bell glass will root quite readily.—G. H.

A Small Tree for a Bed on the Lawn.

Aralia spinosa.

THERE are few hardy plants which have such striking and beautiful foliage as the angelica tree (Aralia spinosa). The species is a native of North America, and is not at all difficult to grow in any reasonable situation. The only point to bear in mind is that, in a very exposed situation, the great leaves may be torn by the wind. The angelica tree makes a fine specimen for the centre of a large bed or to fill out a bed on a lawn entirely

Digitized by Google

with a groundwork of small plants beneath. To secure the full beauty of growth the shrub should be in a position where it can be allowed to remain for some years. In most cases the angelica has a single erect stem and it is best to keep it to this habit. At its tallest the shrub is rarely more than 10ft. high, but much smaller examples may be used with good effects in many parts of the garden. The angelica tree, which is deciduous, flowers in autumn and has small white blooms collected in large umbels, while the stem is clad with strong spines. Propagation is best carried out by means of root cuttings.—L. B.

A Decorative Tufted Plant for the Rock Garden.

PRICKLY THRIFT (Acantholimon) is a low-growing tufted plant which comes from Asia Minor and the East. The flowers resemble those of the statice and armeria, but the habit of the acantholimon is very distinct. Prickly thrift does form branching cushion-like tufts somewhat after the style of the ordinary thrift, but the leaves, instead of being soft and grass-like, are rigid and spiny. Prickly thrift is essentially a plant for the rock garden, and should be placed in light soil in sunny positions, where its evergreen leaves and compact tufts will form an attractive feature all through the winter. In the summer the thrift-like flowers will be highly decorative, so that in all ways acantholimon is a very desirable plant. Propagation is carried out by means of seeds or cuttings. The cuttings should be taken during September and kept in a cold frame through the winter.

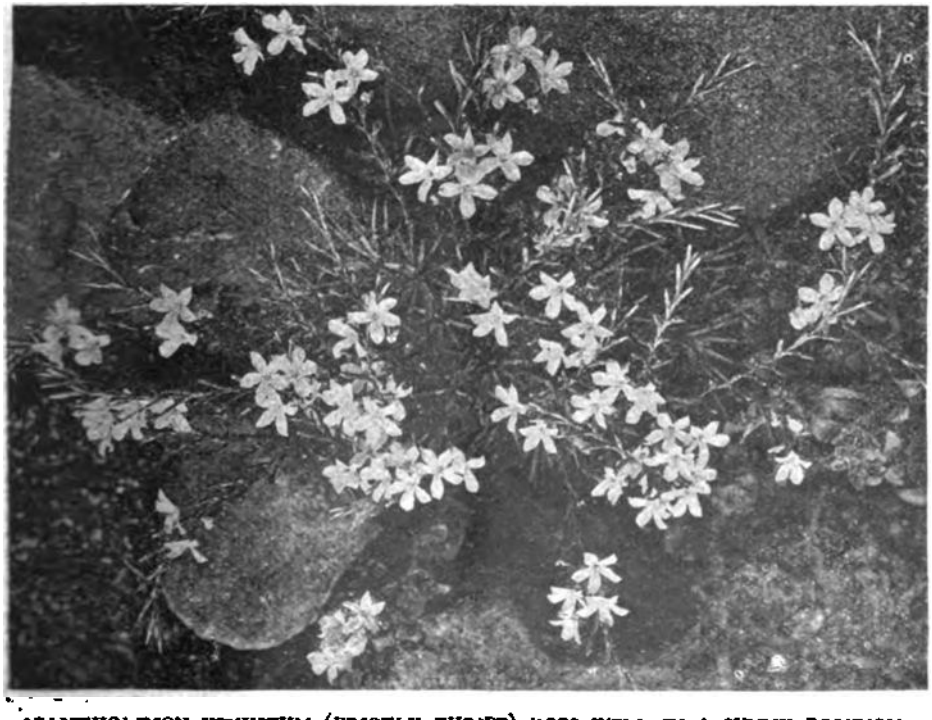
Growth is slow, and it may be two years before the plants are of any size. Many growers say that by layering it is possible to obtain much larger plants in less time. All the acantholimons are hardy and prefer warm, sunny situations in a sandy loam. The freest growing of the prickly thrifts is A. glumaceum, which attains a height of about 6ins and produces quantities of rose-coloured flowers. Other species are AA. venustum and androsaceum, both with pink flowers. A very fine white-flowered species is A. Kotschzi, which has spikes of bloom that rise to a considerable height.

Ramondias for the Shady Rockery.

NO rock garden, however small, is ever completely furnished without a few ramondias, and, moreover, they will succeed in crevice and fissure, where many other plants would fail. They are hardy, easily grown if afforded the right position, and may reasonably be considered one of a choicest dozen of alpines suitable for the rock garden. The principal and best known species is R. pyrenaica, a native of the Pyrenees, where it thrives between rocky boulders. It forms a large flat rosette of dark green crinkly leaves, which fit quite close to the rock. The flowers are borne on stems 3ins. to 4ins. high, and are a beautiful violet-purple, with a minute orange centre. There are also white and rose-coloured forms, but they are not equal to the type. R. servica is another desirable species with slightly brighter green leaves, the flowers being a pleasing shade of mauve. In R. Nathaliæ we have a good variety of R. serbica, which produces flowers of a rich violet shade, with bright orange anthers.

RAMONDIA, ONE OF THE BEST PLANTS FOR A SHADY CREVICE IN THE ROCKERY.

If a few details are considered, no difficulty will present itself regarding the successful cultivation of ramondias. Good drainage is essential, and they must be grown in shade or partial shade, so a north or north-east aspect should be chosen, for they quickly shrivel and die if exposed to full sunshine for any length of time. They also need a position where moisture will readily drain from the flat rosette of leaves, and this fact clearly points to the vertical fissure as the ideal situation for ramondias. Here they will thrive if the fissure or crevice is correctly made so that the roots will receive an adequate supply of moisture during the summer months. When it is necessary to water the plants it ought to be done from behind, so that the moisture percolates among the roots. Overhead watering in summer will sometimes cause the foliage to have a rusty and unhealthy appearance. The staple of the rooting medium is peat, to which is added one third of good quality loam, and a sprinkling of sharp sand. The soil must be made fairly firm around the roots and the plants should be 6ins. apart. Ramondias can be increased by leaf cuttings, similarly to many other of the Gesneriaceæ, but as seeds are produced in plenty, this method I consider the best for increasing the stock. Ramondias may also be increased by careful division during early autumn. Seed should be sown as soon as ripe or at the present time, in pots of peaty compost, but owing to the minuteness of the seeds, no covering of soil is needed. The pots should be placed in a cold frame, covered with a piece of glass, and brown paper, to prevent evaporation, then germination will soon take place. Examine the pots daily and when the seedlings appear, remove the paper and glass, but provide a little shade. Prick off in boxes when large enough and as they increase in size they should be potted off singly, and kept in the cold frame till they are fit for the rock garden.—B.



ACANTHOLIMON VENUSTUM (PRICKLY THRIFT) DOES WELL IN A SUNNY POSITION.

HINTS ON TULIP PLANTING

THE postman's daily burden of catalogues reminds us that the advent of the bulb-planting season is at hand. Although it is not wise to plant tulips too early, no time should be lost in securing varieties chosen for next season's display, as special kinds are frequently only stocked in small quantities. Delay in placing orders results in the supply of substitutes—and the possibility of later disappointment.

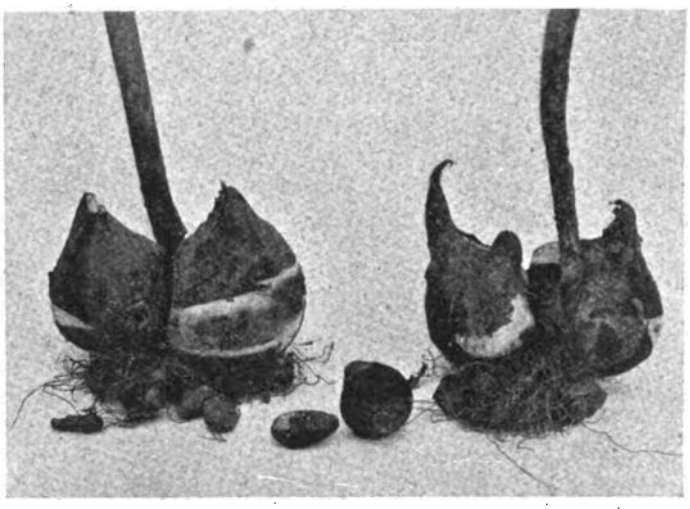
The first bulbs to plant will be the daffodils and hyacinths for Christmas, then snowdrops and early-flowering aconites, followed by iris, daffodils and the general crop for outdoor flowering. The planting of tulips, other than those intended for forcing, should be delayed until a convenient date between the middle of October and mid-November. As a matter of fact, if the bulbs are kept cool and quite dry, they will not come to any harm so long as they get planted before the end of the old year. This knowledge is frequently helpful when mixed herbaceous borders have to be cleared out during the autumn. Daffodils *need* to be planted early: tulips do not. Illustrating the above, I was compelled by force of circumstances this year to keep several thousand Pride of Haarlem unplanted until the last week of January. They were given a sheltered position, and were actually among the first Darwins to flower, the blooms being marketed during the first week of May. If daffodils had been kept out of the ground and planted at the same time they would have taken three years to recover!

The first decision to be made is the choice of a supplier. In this connection, "flowery" catalogue language is not the *best* criterion of quality, nor will the cheapest market necessarily prove the most satisfactory. Tulips, like potatoes, are of all sizes, and the best grades command the best prices. Such as Faust, Teddy, Farncombe Sanders, Pride of Haarlem and similar strong growers, should be the size of a golf ball, while Clara Butt, Picotee, Grenadier, Marksman, Logan Rose, Springtime, etc., will average smaller, according to the natural vigour and size of flower of the variety.

It is an entirely fallacious practice to pay any regard whatever to the brown outer skin. The purpose of this is to preserve the natural moisture until the growing season, at which time it is sloughed off in exactly the same manner as the outer casing of any bud. Unlike the daffodil family, which produce flowers year after year *from the same bulbs*, tulip bulbs are produced in their entirety *annually* and they begin to shrink and shrivel as soon as top-growth commences, rotting entirely away in the course of the season. In effect they transfer their entire substance into foliage and flower, and the root produces new bulbs each year. The old Dutch and English florists carefully skinned their bulbs white when planting them, and I think there is much merit in this practice, as any spores of fungus—"fire," for instance—will, naturally, lurk in the loose outer skin. The bulbs themselves, being purely new growths are, *ipso facto*, healthy. Tulips are naturally gross feeders and, short of planting them in contact with manure, it would be difficult to over-feed them. This is one of the reasons we plant them late in the season. It should be borne in mind that they are not natural Britishers, but only "naturalised." When they begin to grow they want to come steadily on without a check; if they "get going" too soon, the tissues of their fleshy tops will become ruptured with frost and leave them a prey to disease.

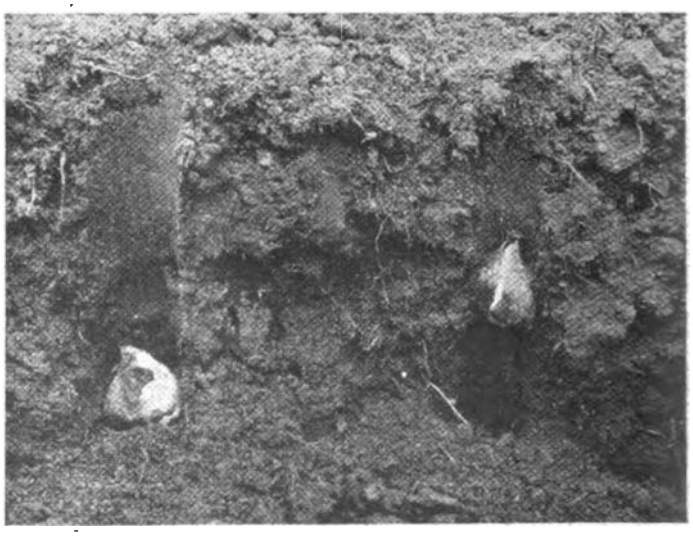
Tulips look their best in clumps or groups and not in a long-drawn-out, straggling, single line. Mixed varieties of good quality, which can be purchased for 5s. to 10s. per 100, should be planted in broad bands about 2ft. wide, sweeping in bold curves from end to end of long beds. Planted this way they should be not less than 6ins. or 8ins. apart, and should spring from a "carpet" of such subjects as arabis, alyssum, myosotis, violas, pansies or polyanthus, which can be chosen according to the colour effect required. In preparing the ground it is well worth while to "do them well," for only by this means will your flowers excite the admiration of your visitors. If farmyard manure is not available, mix equal quantities of steamed bone flour, sulphate of potash and super-phosphate of lime, and dress the land with about 1lb. of the mixture to 4 sq. yds.—more will not hurt. If the land is very sandy, or poor and light, halve the potash and substitute kainit, which has the property of holding the natural moisture of the soil against evaporation and excessive drainage.

The planting depth will depend on the nature of the soil. Deep planting is natural, and has everything to commend it. Perhaps the two strongest points in its favour are that the bulbs need not be moved every year and do not get attacked by slugs, which will not venture far underground. Of course, when one plants commercially in scores of thousands, deep planting is not practicable, on account of the enormous extra weight of soil which would need to be moved. The depth usually recommended is three times the depth of the bulb. This is safe for the bulbs, but not secure from pests or the thrusting spade of the summer-bedding cultivator. Nine or ten inches or even a foot in very light soil will not harm your tulips in the slightest, if they are planted in land required to be "dug over" for later crops of flowers.



NEW TULIP BULBS ARE PRODUCED EVERY YEAR, AND ONLY THE LARGER ONES SHOULD BE PLANTED.
No attention should be paid to the sloughing of the outer skin.

PLANTING A CLUMP OF TULIPS.
Note the distance between each bulb and the depth to plant. From six to nine inches is a good depth to plant tulips.



THE RIGHT AND WRONG WAY OF PLANTING TULIPS.
The bulb should have a firm base on which to rest, with no air pocket between the soil and the bulb.

Digitized by Google

When tulips are grown for house decoration the chief point to bear in mind is that the growing atmosphere *must* be dry and "airy." Nothing is worse than the stuffy, muggy and damp conditions resulting from want of sunshine and ventilation. Unless you are aiming at a definite date of flowering, temperature is a secondary consideration. Frost is to be avoided, of course; but heat, plus lack of sunlight, will result in long and weedy stems. Keep your pots in the best possible light and use rich, well drained *soil*, not fibre.

For outdoor culture it is best to avoid double tulips. If the weather is wet and cloudy at flowering time the flowers are apt to rot. Among the best of the early varieties which will follow the daffodils in quick succession are White Hawk, Brilliant Star (vermilion scarlet), Couleur Cardinal (deep scarlet), Dusart (dark red), Flamingo (clear deep pink), Prince of Austria (rich orange), Joost van Vondel (deep cherry red), Proserpine (carmine rose).

Following these will come the May-flowering and Darwin strains in bewildering variety. It would be a hopeless task to attempt to give a short and at the same time representative list of these. It is always a wise plan to make a note of names of good flowers when seen. The following are moderately priced varieties of good quality:

Red Shades.—Alcmene, Farncombe Sanders, Louis de la Valliere, Nectar, Pride of Haarlem, Petrus Hondius, Prince of Netherlands, Triton.

Pinks.—Comedy, Flamingo, Massenet, Sir Harry, Clara Butt.

Yellows.—Alaska, Bouton d'Or, Canary King, Canary Queen, Moonlight, Mr. Dames, W. T. Ware.

Deep Reds.—Andromaque, Jefferies, Maitre Partout, Millet, Miranda, The International.

Scarlets and Bright Reds.—Scarlet Perfection, Scarlet Emperor, Teddy.

Orange and Chestnut.—Ægir, Boadicea, Marginata.

Lilac and Grey.—Crepuscule, Dream, La Tristesse, Melicette, Remembrance, Rev. Ewbank.

Bronze.—Indian Chief, Prince Albert, Toison d'Or.

There are many varieties of outstanding merit which, for want of space alone, must be omitted; but no collection, however small, should omit Grenadier—brightest orange scarlet; Panorama, the exact tint of a ripe horse chestnut; Prince of Orange, the colour of a Seville orange; Lucifer, an even better flower than the foregoing, rich orange with a rosy flush; Lido and Afterglow, rosy crimson with coppery bronze margin. In the planting of tulips three cardinal points are essential to success: Do not plant too early; do not plant too closely together; and treat them liberally with rich food. H. G. LONGFORD.

THE NEW HERBACEOUS BORDER

Some Hints on Preparing the Soil and Arranging the Plants.

TO those who are contemplating the formation of a herbaceous border to give a wealth of bloom next year, time and labour spent on its preparation now will be amply repaid.

October is the best month of the year to lift and divide quite a number of our lovely herbaceous perennials, so that a few hints on the preparation of a new border will not come amiss at this season.

We must remember that the herbaceous border is to be of a semi-permanent nature and that the plants (unless half-hardy, annual or bulbs) are to remain where planted for a few years without disturbance, so that, as a preliminary to planting, we must see that the land is in good heart.

The soil should be thoroughly drained, trenched to a depth of 2ft. and well manured with horse-manure or, if possible, farmyard manure, placing the manure at the bottom of the trench and covering with the second and first spit of soil. If the drainage is not naturally good, broken bricks or porous drainage pipes should be laid in the bottom of the border. This is necessary to give the border time to settle.

Having prepared the border, we must now consider how and what to plant. It is not possible more than to hint at a few considerations which should guide us in the selection of our material for planting. At the outset it may be stated that, in a small way, it is better to make the border a seasonal border, *i.e.*, one which will give us a bright display of colour during one season of the year only, *viz.*, spring, summer or autumn. It is not at all easy to create a border which will give us a continual supply of flower from spring, through summer to autumn, without appearing very blotchy and ragged at times.

A few words may here be said about colour schemes. The object of a colour scheme is to grow flowers whose colours when taken together produce a harmonious and pleasing effect upon the eye. Strong reds should never be placed next to delicate pinks, nor oranges close to pale yellows. The best arrangement is a gradation of pale colours leading up to stronger colours, though some strong colours, such as blue and yellow, harmonise very well together.

The old idea of a border with plants of a similar height placed together, the shortest in front and the tallest always at the back, is gone. Of course, the principle that a tall-growing plant must not be placed immediately in front of a low-growing one still remains; but, in place of the regular, bank-like arrangement, we have to-day an arrangement whereby masses of tall-growing plants occasionally come prominently to the front edge of the border, forming points, while lower-growing plants may be placed in bays between two points. There must be nothing regular about this arrangement of points and bays. Regularity in a herbaceous border is out of character.

A WELL GRADUATED AND CAREFULLY PLANNED NARROW HERBACEOUS BORDER.

It is a good practice for the amateur to make a plan of his border on paper and to try and work to it, comparing the result with his expectations, noting his mistakes and successes for future uses.

If our clumps have become too large or are dying in the centre, lift them carefully and divide them into pieces with a spade or large knife, selecting pieces for replanting from the circumference of the plant. Do not plant the pieces too close together. The distance apart must be governed by the subject, yet at least 6ins. should be left between the pieces, and in many cases a foot or even 15ins. Firm the pieces well with the fingers, and afterwards tread them in. Do your planting during fine weather, and the plants should soon emit fresh roots and be ready to break into top growth when spring comes.

Bulbs such as crocuses, tulips, narcissi, hyacinths, etc., which will make quite a display of colour in the early months of the year, may be dibbled in the border among other plants.

The following is a list of hardy herbaceous perennials suitable for herbaceous borders: Acanthus, achillea, aconitum, actæa (plant in moist, shady position), Ajuga, althæa, Alyssum anchusa, Anemone japonica, astilbe, bocconia, bupthalmum, campanula (the Canterbury bell), centranthus, chelone, Chrysanthemum maximum, coreopsis, delphinium, Dianthus plumarius (pink) and barbatus (sweet william) dicentra, doronicum, echinops, eryngium, gypsophila, helenium, helianthus, heuchera, kniphofia, lupinus, monarda, myrrhis, nepeta, pæonia, phlox, pyrethrum (do not transplant or divide more than necessary), rudbeckia, salvia, scabiosa, senecio, sidalcea, solidago, statice and verbascum.

THE BUSY MAN'S PAGE

Autumn Work in the Vegetable Garden.

THE summer of 1927, with its abnormal rainfall in various localities, has in too many gardens been fraught with much disappointment, and weeds have grown quickly and become rampant. It is, however, important that an attempt should be made to deal with weeds by up-rooting them by hand, spreading them out, and as soon as possible burning them. At no other time of the year is it more necessary to get the work done than in early autumn. All refuse in the shape of weeds and decaying vegetable refuse should be collected forthwith and put on the fire, as unless this is done there will be a legacy in the spring which will be hard to get rid of. One knows that should the winter be mild such pests as groundsel and chickweed grow apace, and the only remedy to clear the soil is the autumn bonfire. Properly built with wood, such a fire will go for days if banked up, and the ashes if collected will come in useful next spring. Until the ground has been made free, no digging should be attempted, and when this is set about the rougher it is left the better. If any lime is needed, now is the time to give the order, and the same in respect to manure, as the latter may often be more readily obtained during winter than in spring, when so many are wanting it. On heavy ground it is sometimes possible in October in rural and suburban districts to obtain a few loads of leaves from various councils. In using lime it is well not to forget to scatter some on the ground occupied by winter greens, as this will exterminate many pests.

Grease-Banding of Fruit Trees.

NO matter how few fruit trees one possesses, the operation of grease-banding ought never to be omitted during the autumn months. The object of grease-banding is to prevent the female insect of the winter moth from climbing up the stems of the trees, which it must do to get to the branches, where it deposits its eggs close to the buds.

On a standard tree the grease-bands are put on the stems about 3ft. from the ground, and on half-standards and bush trees as high up from the ground as possible. The bands can be bought from any horticultural sundriesman, and are made about 1ft. broad and 18ins. long. Tie a paper round the tree twice, one tie being 3ins. below the top of the paper and the other tie 3ins. from the bottom. Leaving the 6ins. of the centre of the paper to be covered with the grease, which ought to be bought prepared. Several brands are advertised in the pages of this paper.

The Correct Tools for the Garden.

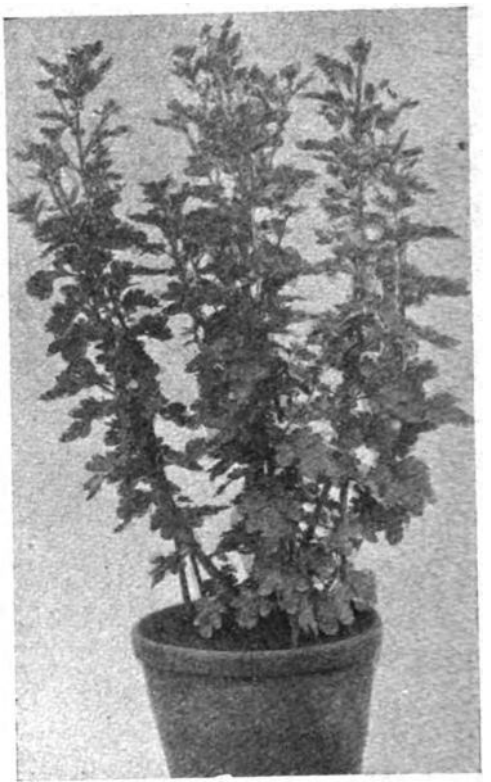
GOOD gardening cannot be done without the right tools. There are two kinds of forks, and the soil will work better with the right one. For heavy soils the one with the thin round prongs is best, being strong and light. But on light soils the wide flat prong is preferable, as the soil stays on better. A shovel is much better than a spade for heaping sand or gravel. Three kinds of rake are needed: firstly, an 18in. one, for raking stones, etc.; an 8in. one, for going in between growing plants; and a wooden one, for raking grass when cut. A hoe and mattock are very necessary for good cultivation. Secateurs with both blades sharpened are best for hedge cutting and pruning. Other small tools, such as a bedding fork and trowel, are essential. You should have a dibber and drill cutter also.

Lifting and Potting Chrysanthemums.

GOOD chrysanthemum blooms can only be achieved by attending to the smallest details of culture. Absence from home and other claims upon the time of growers often preclude them from consistently serving the best interests of their plants, and for this reason plants grown in pots from start to finish in some gardens are most disappointing and unsatisfactory.

It has become a very common practice in the case of plants that are grown for cut flowers to plant outdoors goodly breadths of the more popular decorative varieties. Such plants will be found in superb condition for lifting during the coming weeks. They may also be lifted from the open border, and either potted up into large pots or placed in boxes or any other receptacle that can be drained and that will accommodate the ample roots of these plants. The plants should not be lifted if the ground is at all dry, as the soil would fail to adhere, and the check would be felt more severely in consequence. In dry weather give the plants it is intended to lift a good soaking with clear water an hour or two before the lifting and potting are to take place. Also see that the growths are lightly but securely tied to stakes and a tie made round the whole of the plant; this will facilitate the lifting process. The lifting should be done with a spade, this being inserted all round the base of the plant so that it may be lifted with a good ball of soil adhering to the roots. Unnecessary soil should be removed with the hands, so that the ball of soil and roots may be comfortably adjusted in the pot or box got ready for its reception. The pots should be large, clean and carefully crocked. Cover the crocks with a double handful of turfy loam or decayed manure, and a small quantity of prepared soil should be placed on this. A suitable compost may be made up of loam, leaf-mould and coarse sand, well mixed before using. After adjusting the plant in position in the pot, work in the soil, making this very firm, assisting in this by a few sharp raps on the potting-bench. Subsequently water in, standing the plants on sifted ashes or boards in a semi-shaded position for a few days to recover from the check experienced. Place them in the greenhouse as soon as frosty weather makes this protection necessary.

A CHRYSANTHEMUM IN EXCELLENT CONDITION FOR LIFTING.



THE SAME PLANT AFTER POTTING AND STAKING.

Gooseberries.

OLD, worn-out shoots should be removed now, retaining, in established trees, sufficient strong, young growths with which to replace the discarded branches.

Wireworms.

THESE are the larvæ of small beetles and are the most persistent and destructive of all ground vermin. The worms attain a length of ¼in. to 1in., and live for a period of three to five years in their subterranean homes. Soot is a popular remedy, and "Vaporite" has been used with successful results. Many gardeners prefer to set traps for them, for which purpose thick slices of potato or beet prove the most alluring bait. Mark the spots where the traps are buried and examine them every few days.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Treatment of Autumn Window-Boxes.

SUMMER flowers are nearly over, and it is time to begin preparations for the spring show of blooms in the window. So many people live in towns, where it is often not possible to have a garden, that special advice to those who grow their flowers on the window-sill is not out of place.

Bulbs are pre-eminently suitable for window-box cultivation, especially hyacinths, crocuses and daffodils, and at comparatively little expense a window-box can be made a feast of beauty.

I assume that you already have your window-box made and in position, but in case this is not so, these are the points you must consider.

Good straight wood should be used for the box, well seasoned, of course. If there is the slightest doubt about this, a small binding of metal should be nailed round the corners to prevent them bursting open. The box should be at least 6ins. deep, inside measurement, and 6ins. or more wide.

It should be secured to the window frame with a small bracket—*Safety First!*—and should also be raised a little from the sill so that the dampness does not rot it. Holes must be made for drainage, the inside of the box charred, and a layer of crocks, concave side downwards, put over the drainage holes.

Special care must be taken to obtain good soil, as, owing to the limitations of space, the condition of the soil matters more than in the garden. The ideal is a fibrous loam and leaf-mould, into which two or three handfuls of bone-meal have been mixed. A layer of manure just over the crocks is good, but it should be well decayed.

Treatment of Old Soil.

If you have an old box with the soil in a rather exhausted state, turn it out. See that the crocks are clean, If they are slimy and sour, wash them well before again putting them back. Mix into the old soil a quantity of decayed leaves and some superphosphate of lime—say, about two handfuls of the latter to a window-box.

Partly fill with soil and press this fairly firm before planting the bulbs. Then place them in position, and cover with soil to within an inch of the top. Firm this well and then water. Do not overdo the watering, as little moisture will be needed until the bulbs begin to grow.

Small veronicas, box or other dwarf shrubs do well during the winter, and if these are used in conjunction with the bulbs, the boxes will not have that empty and depressing look which so often is seen when the summer flowers are over.

Flowers in Succession.

Bulbs grown in window-boxes naturally flower at different times, according to the kind of bulb, and if a judicious selection is made, an almost constant succession of blooms can be secured. If planted together, crocuses will flower first, hyacinths and daffodils next, and tulips last.

If you want to ensure your box being in full bloom all at once, try mixing with your bulbs such things as forget-me-nots, arabis or other free-flowering subjects, which will flower both before and after the bulbs.

Autumn-Sown Annuals.

EARLY flowers, strong bushy plants and a sturdy constitution which is not easily ruined by inclement weather or the attacks of insect pests—these are the advantages resulting from autumn sowing of hardy annuals in the flower border. Now is the time to clear away faded Canterbury bells, clarkias, candytuft and other short-lived plants, and to sow in their place a few annuals, such as calendula (Orange King marigold), eschscholtzia, nigella and sweet alyssum. Sow thinly where they are to flower, so that transplanting may be avoided, and early flowers next year will be assured.

Pool Garden at the Foot of Trees.

IN the accompanying picture, a charming idea is shown as to how to introduce a water garden in a garden which contains large trees. A cement retaining tank is built level with the surrounding lawn, and this is cunningly given a natural appearance by the use of an edging of rockery stones. The various water plants are employed to add to the naturalness of the effect.

THIS SMALL POOL HAS A NATURAL APPEARANCE ALTHOUGH ONLY IN A SMALL GARDEN.

Bulbs for Home Decoration.

NO other class of plants is so well adapted for cultivation indoors as "Bulbs."

Snowdrops and daffodils can grow and flower even during the dark days of early spring, long before the summer flowers have found their stride.

The daily arrival of bulb catalogues at this season reminds one that the planting season has come round again. Out of doors it is already time for snowdrops, crocuses, scillas and winter aconites to be planted.

Indoors the preparations for planting bulbs should be proceeded with as quickly as possible. The secret of successful bulb-growing is to develop as many roots as possible before any top growth commences. If bulbs are planted too late they are never satisfactory.

Lifting Early Potatoes.

THERE is no advantage gained by allowing the tubers of potatoes to remain in the soil after the tops have turned yellow. Early varieties, like Sharpe's Express, can now be lifted in most districts. Before storing them away, it is advisable to lay the tubers on the surface of the soil in full sunshine until they are thoroughly dry. Pick over them and remove any diseased tubers. It is worth while, about a fortnight after the tubers have been in store, to turn them out, when diseased tubers will be more easily detected. Potatoes should be stored in a cool, well ventilated shed or cellar. They can be stored in sacks, provided these are well covered to keep out the light.

This Week in the Vegetable Garden.

THERE are several things requiring to be done in the vegetable garden. Make a sowing of onions for next year. Two rows of 10yds. length each, would be sufficient for the year's crop for most households. Ailsa Craig and Bedfordshire Champion are two old, but excellent varieties. They can be sown an inch deep in drills 12ins. apart. Half an ounce of seed is sufficient for the two rows.

The advantage of autumn-sown onions is that they avoid the attacks of the onion maggot, as the necks have become hardened by the time the fly makes its appearance in May. Onions sown now need not be thinned until next spring, when the thinnings can be used for salads.

Beds of Hyacinths.

ALTHOUGH hyacinths are still rather dear, many amateur gardeners are so fond of them that they cannot do without them in the borders. Hyacinths usually deteriorate from year to year in this country, and the bedding quality sold by all bulb merchants is generally quite good enough for outdoor use. The bulbs should be laid on the surface of the bed, in the position where they are required. Then plant each one carefully with a trowel, allowing the base of the bulb to rest firmly on the soil. About 2ins. of fine soil should cover the bulbs. Mark the spot where the bulbs have been planted with a few sticks or labels so that you do not disturb them if you have to fork the soil near them.

NEW ROSES WORTH NOTING

AFTER the late frosts and heavy rains it is pleasing to record a beautiful display of July blooms in this district. Among the new varieties that I have tried and can recommend to amateurs are the following:

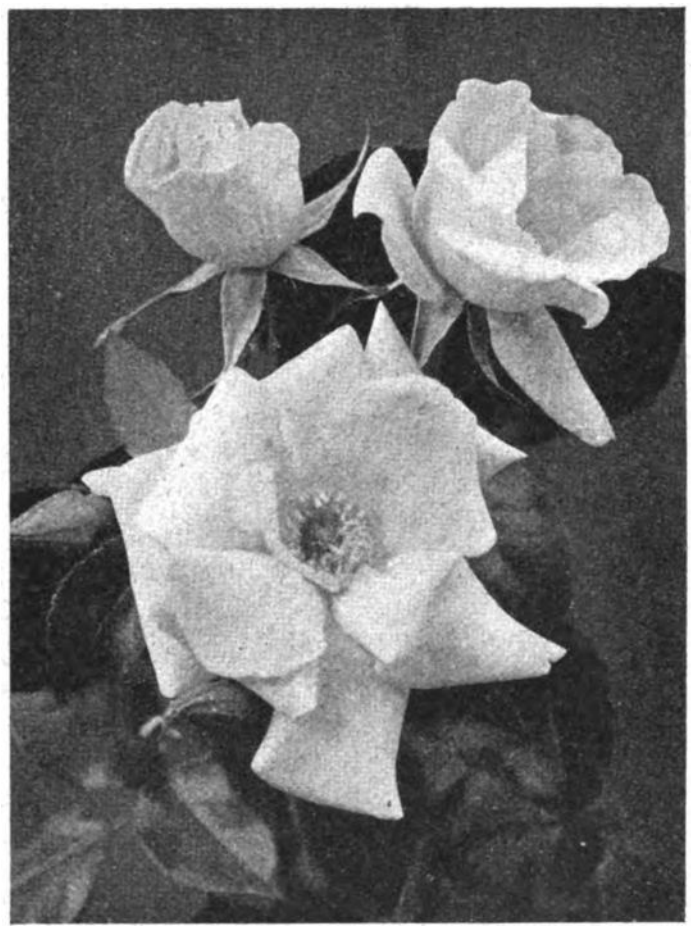
Billy Boy (Pernetiana).—A deep yellow, semi-double, with bright green foliage and no sign of mildew, compact habit and very free flowering. When better known there will be few amateurs who will not want this truly charming rose in their collection, which has the additional virtue of being sweetly scented. No rose has pleased me more—making allowance, of course, for the difference in class—since I first grew Shot Silk.

Another semi-double, which is worth growing if only for its unique colour, is *I Zingari*, orange and scarlet, reminding one of the colours of the old cricket club of that name. The blooms are rather thin, but sweetly scented and plentiful. A bed of this variety would be extremely beautiful.

Marcia Stanhope.—The new fragrant white, has perfectly shaped blooms with high pointed centres and of a size that makes it valuable for exhibition purposes, and it will doubtless take the place of Druschki in course of time, from which it is a seedling.

Holt Hewitt.—Rich velvety crimson, reminding one of George Dickson, but has the merit of stronger stems than the latter; sweetly scented, free flowering and blooms of exhibition size.

Ivy May.—A delightful little rose of Mme. Butterfly parentage, with the latter's deepest colours intensified; perfectly shaped buds and so free flowering as to make disbudding a necessity in order to see it at its best. Although it has been rather prone to mildew, it has proved a decided acquisition, being very attractive in all stages from the bud to the open flower and has a strong refreshing perfume.



A ROSE TO PLANT THIS SEASON.
Billy Boy, a charming deep yellow semi-double variety.

Clovelly.—Rich satin pink, beautifully shaped buds on long stout stems; scented, of strong habit and retains its shapeliness when fully open.

One of the most arresting roses has been *Wilhelm Kordes;* of perfect shape and colour somewhat resembling Georgeous, but of so vivid a type as to render it difficult adequately to describe its remarkable colouring; it has tough dark green foliage, mildew proof, and no amateur can go wrong in adding this beautiful specimen to his collection.

This fine new Pernetiana rose was illustrated and described in THE GARDEN, August 27th, on page 565.

I suppose *Lady Inchiquin* can no longer be styled a new rose, but to those who have not yet tried it, I can thoroughly recommend this beautiful orange cerise variety. The blooms are large and full, while it is sweetly scented and valuable for all decorative purposes.

Charles P. Kilham.—This rose has been sent me by the raisers, Messrs. Beckwith and Son, for a trial, and has produced blooms of a very delightful and attractive nature, which are of excellent shape both in the bud and when open, while the colour is something like Mme. Herriot, brilliant orange red suffused with golden scarlet; the foliage is clean and the habit good. It is a welcome addition to roses worth growing and will be in great demand when better known.

Derby. R. C.

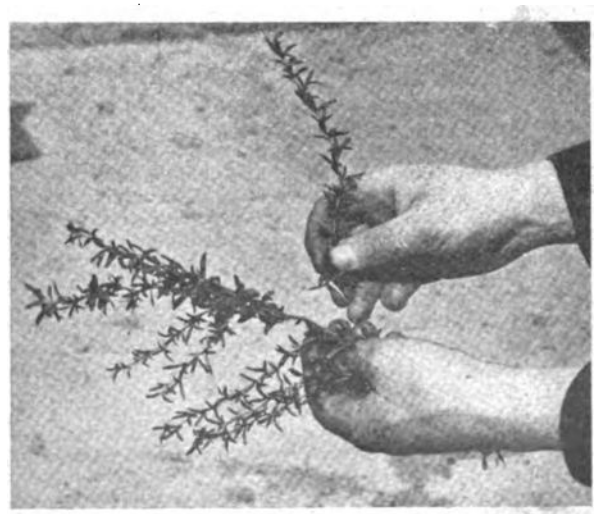
HOW TO TAKE SHRUB CUTTINGS

This is the time for increasing the stock of many shrub and border plants by the taking of cuttings and inserting them under glass. The following article gives details on how to proceed with this interesting work. All amateurs should become familiar with this work.

THERE is no more interesting branch of gardening than the increase of plants by seeds, cuttings, layering, division or grafting. Of these several phases that of propagation by cuttings is the one which can be practised with the greatest degree of success by the thousands of amateur horticulturists who find in gardening a most captivating and healthy hobby.

Autumn, which for our purpose is September and early October, is the best season for increasing many shrubs and border flowers by cuttings in cold frames, under bell glasses and hand lights, or with only a wooden box containing 4ins. or 5ins. of sandy soil, and a sheet or two of glass to cover the top, making it fairly air-tight, to prevent the drying up of the cuttings while roots are being formed.

At this season growth is practically completed, but the wood is not very hard, with the result that, combined with the warmth in the ground, more or less warm autumn days and a conserved moist atmosphere under the glass, the cuttings commence rooting almost at once.



REMOVING A CUTTING WITH A HEEL FROM A BRANCH OF BERBERIS STENOPHYLLA.

A warm, sheltered and somewhat shaded position suitable for the purpose of rooting shrub cuttings can be found in most small gardens, and can be readily secured in large gardens. From most points of view a north-west aspect is the most suitable. It is sheltered from the north-east winds, and very little sun will reach the cuttings to dry up the moisture before they are well rooted.

When it is intended to root cuttings in considerable numbers, a movable wooden frame with a light or lights, as depicted in the accompanying illustration, is very useful and adaptable. A bed of sandy soil can be made up in the frame, and the lines of cuttings inserted and labelled with name and date of insertion. A good average distance is to dibble the cuttings in 3ins. to 4ins. apart in the lines, with a distance of about 6ins. between the lines. This, however, is

Digitized by Google

subject to variation, according to the size and type of cutting, also closer "dibbling in" can be practised when it is intended to lift and pot, or transplant, the rooted cuttings in spring, compared with a wider distance apart desirable if the frame, hand lights or bell-glasses are to be removed in spring and the young plants left in position until autumn.

In the case of small numbers of cuttings, very many shrubs can be rooted successfully under bell glasses or in hand lights in a shady border. Prepare a bed of sandy soil, over this place a thin layer of sand, mark on it the sizes of the respective bell glasses or handlights, and dibble in the cuttings. Water well with the spray from a fine-rosed watering can and cover with the bell glass or hand light.

The length of the cuttings will, obviously, vary with the type of growth of the shrubs, from as small as 2ins. or even less in the case of hardy heaths, to 4ins. to 6ins. with strong-growing shrubs, which include the berberis, some of the cotoneasters and the rambler roses. There are two types of cuttings (1) with a thin heel of old wood at the base and (2) cuttings with a base cut just under a joint, or node, where the leaves have been removed. To secure the best cuttings with thin heels of old wood cut off branches which can be readily spared from the parent bush. Hold one of these in the left hand, in this case Berberis stenophylla, as depicted in Fig. 1, take the proposed cutting between the thumb and first finger of the right hand, and give it a gentle downward pull. It may come away with rather more "heel" of old wood than is required, but this can be readily "pared off" with a sharp knife. Remove the lower leaves from the part of the cutting to be inserted in the soil. The discretion of the operator must be used as to whether the top of the cutting is left on or shortened if weak or too long. The cuttings illustrated of the rock rose, Cistus cyprius, serve as a very good example of cuttings made with a node or leaf-joint as a base.

PREPARED CUTTINGS OF CISTUS AND BERBERIS.

Note the length of the cuttings and how each has been taken. In the case of the cistus cuttings the basal leaves have been removed, while in the berberis cuttings the thin heel of wood can be seen.

A good average depth to insert cuttings in a cold frame or under hand lights and bell glasses is about one-third the length of the cutting, thus leaving two-thirds above the soil.

Stiff cuttings may be pushed carefully into rather loose sandy soil and be made firm by watering. Use a dibber (pointed stick) to make holes to insert rather soft or fragile cuttings, but the surface sand must be dry to run in and fill up the hole when the dibber is withdrawn and the cutting inserted. Label, and water to settle in position and prevent flagging or wilting of the cuttings.

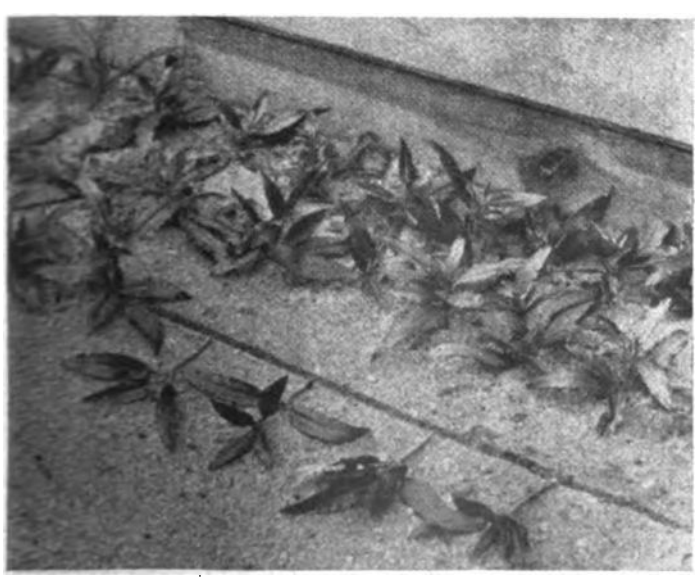
Dibbling the cuttings into beds of prepared soil and covering with bell glasses is largely practised, and the soil can be kept more evenly moist than when the cuttings are inserted in pots and stood in a cold frame. The desired even moist conditions, however, can be secured by inserting the cuttings in pots and plunging in sand or light soil in a border and covering with bell glasses. One point in favour of this method is that the pots can be lifted up and critically examined. They may even be inverted in the hand and the ball of soil carefully knocked out of the pot to see if the cuttings are rooted. Many more hardy shrubs can be readily increased by cuttings than is generally understood. A very important point is that the soil must be of a light, porous character even half sand may be added to rather heavy loam.

While both evergreen and deciduous shrubs root very well in cold frames and under handlights and bell-glasses, it is for evergreen shrubs that is of the greatest the glass protection value.

A few of the best known examples include Osmanthus Delavayi, Viburnums Tinus, Henryi and rhytidophyllum, yews, hollies, buxus (box), cistuses, lavender, helianthemums, cotoneasters, the smaller-leaved rhododendrons, rosemary, cytisus and genistas, barberries (both evergreen and deciduous) and Lonicera nitida.

After-Treatment.

It is not sufficient once the cuttings are inserted in a suitable medium to leave them until they are rooted. They should be examined from time to time and immediately on rooting should be removed from the cutting bed or frame and potted on in a suitable soil compost. This is necessary where cuttings are being rooted in pure sand, since no nourishment is available to the new roots and unless the rooted cutting is given food material in the way of a loamy soil, it will soon die off. The change from the compost of pure sand to that of soil should not be brought about too rapidly, however, as the cutting may suffer a check by the quick change. Rather let it be brought about gradually till the rooted cutting becomes a properly established plant, when it can be potted on in easy stages. A. O.



INSERTING CUTTINGS OF CISTUS IN A COLD FRAME.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

IN addition to last week's note regarding the difficulty of obtaining sweet pea seeds in time for September sowing, a plotholder tells me that simila trouble is experienced in connection with the boxing of seed potatoes. According to modern methods of culture, both early and late varieties of tubers should be sprouted in boxes as a means of increasing the weight of the crop, but according to my informant when new seed has to be bought, it is seldom available before the end of January. Little benefit is to be gained by boxing seed of first early potatoes at that late period as they are usually put in the ground at the beginning of March, should the weather prove favourable. The south Ayrshire and Galloway farmers, who are the principle raisers of early potatoes in Scotland, have practised the sprouting of tubers for the past thirty years and they have already begun to box their seed for next season, thus proving that the process of sprouting should be slow. These farmers save their own seed and when a change of seed is made at two or three yearly intervals, they purchase stocks from one another. The amateur gardener may therefore solve the seed potato problem by following the example of the farmers and save their own seed, if the crop is free from disease and rogues. The system that is sometimes followed by small gardeners of using ordinary household supplies of potatoes for seed purposes is an evil one and should not be encouraged, because of the liability to disseminate disease and the prospect of growing a crop containing possibly half a dozen different varieties. Rather endeavour to make a careful selection of your own seed, choosing tubers about the size of a hen's egg that resemble each other in colour, shape and eyes and box them within the next two or three weeks. Even though the experiment should turn out a success, remember that a change of seed is advisable after the second or third year.

The registration of a few degrees of frost about the middle of the month was a timely reminder to gardeners that they may wake up some fine morning and discover that the dahlia bloom is over for a season. When this happens the roots may be lifted and stored away for the winter without unnecessary delay. The operation, however simple, involves the exercise of care, as the tubers are brittle and may be easily damaged in the process. See that the fork is inserted some distance from the stem, and if the clump does not come away freely, loosen the soil surrounding each plant. Cut down the stem to within 6ins. of the root and attach on each a label bearing the name of the variety, so that identification may be made easy in spring time. The great danger to dahlias during winter is not frost, but damp, which causes the tubers to rot, and precaution must therefore be taken to prevent loss. In the first place the roots should be in a thoroughly dried condition before they are stored. This may be accomplished by removing the soil and drying the tubers by exposure to the sun on a fine day or by placing them on the staging of a cold greenhouse for a few days. Then the place to be selected as a winter store must be thoroughly dry and not necessarily dark. Some growers hang the roots upside down, others place them in boxes in a similar position, but whatever system is adopted, it is a wise plan to make an occasional inspection of the tubers during the three or four months they are kept indoors. Although dahlias are not supposed to be hardy enough to remain in the open ground over winter, several amateurs of my acquaintance left their Coltness Gem undisturbed in the border, and strange as it may appear the mortality was trifling, despite the rigorous weather experienced at the end of 1926 and the beginning of 1927. Growth was more vigorous and the plants came into bloom earlier than those raised from cuttings. Where a large quantity of the dwarf dahlia is grown and the owner is prepared to take the risk, ordinary prudence demands that some protection should be afforded.

Another garden favourite that requires attention at this season is the gladiolus. Unlike the dahlia, the foliage takes a long time to wither and it is not advisable to wait until it reaches that condition before beginning the winter treatment. The corms may safely be lifted when the bloom is past and the foliage has begun to lose its freshness or show signs of fading. After remaining in an outhouse or shed for a few days to dry, the stems should be cut away, and on removing the earth it will be discovered that the old corm is in process of decay and that a new one has been formed on the top of it. By a gentle pressure of the fingers the two can be easily separated and the new corms should be stored away in boxes of dry sand until the time arrives for starting them into growth. A damp or warm atmosphere is injurious as the corms require to be kept cool and dry while in a dormant condition.

Very few amateurs, I imagine, are familiar with parrot tulips, yet they have been in existence for ages and there is probably no other bulb that is capable of making such a gorgeous splash of colour in the flower border after the earlier tulips are over. These brilliant flowers of great size and of varied and grotesque shapes are seen at their best when grown in clumps, and they are also useful for decorative purposes indoors as they stand a long time when cut. The late Rev. Joseph Jacob also recommended that the parrot tulips should be grown in hanging baskets and the bulbs arranged in such a way that some will grow through the sides and some out of the top. By this arrangement the great ragged blooms hang down in charming confusion and display their quaint colourings and weird forms to advantage Three of the best varieties are Café Brun, reddish brown and yellow; Constantinople, dark red; and Cramoise Brilliant, deep crimson, with black star-shaped centre, each of which cost about 2s. per doz., but those who can afford a novelty at double that price should experiment with Fantasy, whose soft salmon rose colour resembles the popular Darwin Clara Butt.

Although it is somewhat late in the season, I have just completed a test of some thirty varieties of lettuce under trial at Cathcart Nursery, with the object of finding out which sorts remain longest in good condition and do not run readily to seed. A number of the earlier varieties were beyond the sphere of usefulness, but of those sampled I would place Webb's Wonderful first, Blonde Stonehead second and Austin's Matchless third. They are all of the cabbage type and were large, crisp and of excellent flavour.

Three novelties of exceptional merit, consisting of two seedling chrysanthemums of the early flowering type and a seedling carnation, received a first class certificate at the Glasgow Flower Show last week. The latter is a large crimson flower measuring 4½ins. across, which some authorities regard as an improved Red Laddie. It was raised by Mr. Johnston at Springburn Park and the specimen plant carried several blooms in different stages of development, with non-bursting calyx. Messrs. Torrance and Hopkins, Busby, are responsible for the introduction of a new colour in chrysanthemums which may be described as helio-rose on one side of the petal and biscuit on the reverse. This incurved novelty is a sport from Lizzie McNeil and is to be known as Mrs. John Wilson. The other new introduction is also incurved in form and has been called after Mrs. Quinten McFadyen, the wife of a well known grower of pansies and violas at Carluke. It is the production of Mr. Alex. McAlpine, Tollcross, who has raised some of the most popular varieties in cultivation to-day, but good as Euphie Ritchie, John McAlpine and Mary A. Houston are, he considers, his latest creation to be his best. The colour is a pretty combination of bronze on the inside of the petal and gold reverse, and a notable characteristic is its robust growth and long flower stems exceeding 2ft. in length. ST. MUNGO.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful and interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF-GUINEA HINT

When Planting Cabbages.

When planting cabbages the soil should be very firm, as loose soil tends to make the plants grow flabby and soft. However, firm soil usually contains a large number of weeds, and these should be cleared while hoeing the ground. Then the line should be set and number of holes made with the dibber. These holes should be filled with water which must be allowed to run away. While this is going on the plants should be drawn from the seed-bed and the lower portion of the root cut off. They should then be tied in bundles and allowed to stand in a bowl of muddy water for about an hour. This allows the plants to draw up a supply of water. Then the plants should be placed in the holes and pressed firmly in. A little dry soil placed around will prevent immediate evaporation of the moisture.—G. W.

Leaf-Mould for Potting.

If fresh oak and beech leaves are gathered and put into sacks and kept in a warm place near a stove or copper and, when dried, rubbed through a ¼in. sieve, the best form of leaf-mould for use for potting purposes is obtained.—M. H. G.

Artistic Arrangement of Flowers.

Gladioli are best grouped with their own foliage in bronze vessels. They last well and their buds open in succession. Montbretias, with their art shades of colour, are equally effective if similarly arranged. Then again, Viola cornuta lends itself to the best advantage when placed with its foliage in a small brown jug. Chrysanthemums and Michaelmas daisies should be cut with long stems and placed in tall receptacles, so as to avoid stiffness. No matter what kind of vessel is used, nothing of a decorative character should be utilised which would detract attention from the flowers themselves. Soft neutral brown is always harmonious.—A. L.

WHAT OUR READERS SAY

SPRING BEDDING PLANTS FOR A NARROW BORDER.

SIR,—Where space is very limited, such as in towns, a border of 2ft. or 3ft. can be made a blaze of colour in spring by planting wallflowers, tulips, forget-me-nots and a few polyanthus in the following way.

The wallflowers, Fire King, a very brilliant flaming red, and Cloth of Gold, can be used and planted in clumps, Fire King at the back, Cloth of Gold in front. Plant five or six in each clump about 10ins. between each plant, leaving good spaces for the tulips, which should be planted twice their depth, this brings them into bloom at the same time.

Along the edge can be planted a few forget-me-nots alternately with polyanthus. No border could be brighter than this, and, with the exception of the polyanthus, the plants can all be cleared ready for summer bedding.—A. J. F., *Ampthill*.

ROSES *v.* HERBACEOUS FLOWERS.

SIR,—Up to last year, and for very many years, the position of honour has always been allotted to the roses. I have been fairly successful, too; but year after year there has always been an element of doubt in my mind. Did the Queen of Flowers justify her enthronement, did she repay me for the devotion to her cause? I was proud of my successes with Betty Uprichard, Shot Silk, Mabel Morse, Caroline Testout and others; but, generally speaking, my rose-bed was unsatisfactory, patchy, uninteresting. It had that half-empty appearance, and, despite the efforts of more than thirty choice bushes, it failed completely to capture the imagination or to impress the memory.

On the other hand, the herbaceous borders were glorious in their diversity of bloom; the heleniums, Shasta daisies, gaillardias, scabious, lupins, delphiniums, even the little groups of candytuft or alyssum gave one complete pleasure.

However, in the effort to be strictly honest with myself, I determined this season to try a change. Out came every bush rose—every one—and in their places were planted an Excelsa, Dorothy Perkins and an Albéric Barbier. These as a background to Coltness Gem dahlia, one or two clumps of nepeta (which overhang into the path), and masses of Viola Maggie Mott, that perfectly delightful bloomer which never fails me, and just an odd clump or two of erigeron.

Not an elaborate scheme, by any means, nor was it designed with the idea of competition with my neighbours' rose-beds; yet all my visitors are entranced, and their adjectives of praise confirm my own opinion.—A. BLYTH, *Burnage, Manchester*.

CONSTRUCTING A LILY POND.

SIR,—With the approach of autumn many will shortly be planning garden reconstruction or alterations, and as the lily pond is finding favour in many schemes—and certainly this gives a touch of quaintness and is a pleasing feature—I give the details of one I have constructed by what I consider the cheapest and quickest method. It has proved quite satisfactory. My pond is 12ft. by 6ft., with curved ends, and 2ft. 6ins. deep, and is surrounded by grass.

First of all I procured some stone slabs 18ins. by 9ins., which were bedded down to the shape of the pond and sunk 3ins. below ground surface and tested with spirit level. The pond was then excavated so that the slabs overlapped the cavity by 3ins. Some wire netting 3ft. wide was fastened to the sides by means of 12in. iron stakes with hooked ends. The spare 6ins. was bent over under the slabs on which a layer of cement and sand, 3ins. thick, was put to raise the slabs to proper level.

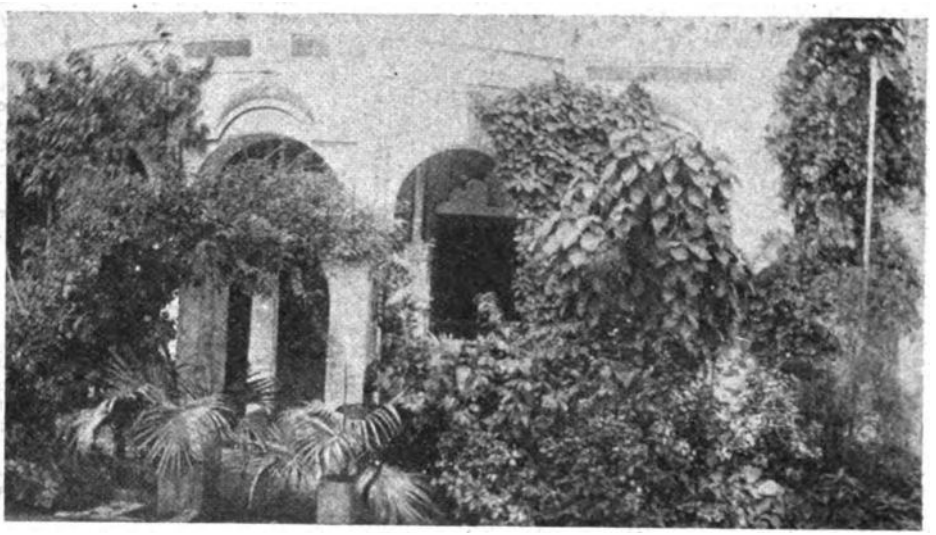
The sides were then floated 2ins. thick with a mixture of two parts cement, one part washed sand and one part pebble dash, a home made wooden float being used for this, which leaves a rough surface for the second coat. For this second coat, two parts cement and one part sand were used and applied with a steel float, which gives a tighter finish to resist the water. After this was dry a pure cement wash, made to the consistency of a thin cream, was brushed on and a second wash, made thinner, was again given after two days interval.

When dry the whole was lightly sprayed for a day or two.

This method dispenses with the laborious task of building staging for concrete and is equally effective as a brick foundation, which for a pond of this size would be expensive. The total cost was £2 and the loss of water is negligible and is compensated by the rainfall. To freshen and sweeten the water the hose is placed at the bottom occasionally and the pond allowed to flood the grass for a short time, of course, where circumstances permit, an overflow pipe would be better.—A. CUTHBERT, *Ilford, Essex*.

CLIMBERS IN AN INDIAN GARDEN.

SIR,—I am very glad to let you know that I am a subscriber of your most interesting and useful paper, THE GARDEN, and have long had a desire to send a photograph of my garden. It shows an attractive way of changing a barren, narrow platform, in front of a private residence, into a place of continual interest, by introducing several suitable plants. A narrow 1ft. wide border filled with

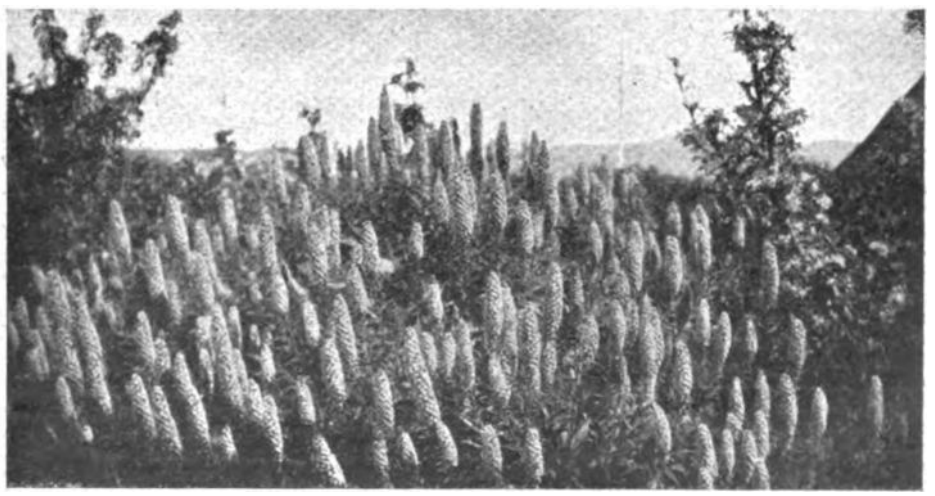


CLIMBING PLANTS DECORATING A BALCONY OF AN INDIAN GARDEN.

a rich compost, furnishes a comfortable abode to the magnificent poinsettia. The path to the building is guarded by two palm tubs, and on an arch is a jasmine plant. The perennial verbenas and choice mirabilises revel in luxurious growth along the platform's whole length. The building is draped with Quisqualis indica on its right and Hiptage madablota on its left, while Aristolochia elegans shows to full advantage on a middle arch.—BHAGWALI PRASAD, *India*.

A FINE ECHIUM TREE.

SIR,—I enclose a photograph of an echium tree which may be of interest to your readers.



AN EXCEPTIONALLY FINE ECHIUM, CARRYING OVER THREE HUNDRED BLOOMS.

It is growing in the garden at Coverack, Cornwall.

This spring the tree had 320 large cobalt blue blooms, which is stated to be a record, as 150 is the largest number of blooms reported on any tree grown in England. The tree measures 21ft. across and is 6ft. high.—A. F. CALVERT.

FRUIT AND KITCHEN GARDEN

Present Treatment of Asparagus Beds.

ASPARAGUS beds are, generally, regarded with much interest early in the spring, because this choice vegetable is about to become fit for use. As the summer passes the beds are neglected, weeds are allowed to grow and ripen seeds, which are conveyed to other quarters, and so the whole garden becomes weedy. Large weeds in the asparagus beds take up much nourishment and exclude light and air. Asparagus plants require all the light, sunshine and air that can be obtained naturally throughout the season. Weeds found in the alleys between the beds may be hoed off, and afterwards the soil should be lightly forked up to ensure the free passing away of rain water—as the alleys get panned down hard during the summer months. All weeds found growing in the beds should be hand-pulled, taken at once to the garden smother and there burnt. It is a mistake to leave maturing weeds on the soil of beds, because their seeds soon fall and the result is a green surface of seedling weeds. The old asparagus stems are now hardening, but they should not be cut down before they are thoroughly matured. Some attention should now be given to the planning of the new asparagus beds. Select the site, prepare the manure and get the ground clear of crops in good time for the necessary trenching to be done.—HANTS.

Autumn-Fruiting Raspberries.

A FEW plants of one or other of the autumn fruiting raspberries should be grown by every amateur who is fortunate enough to possess a garden large enough to allow him to cultivate fruit. Given good weather during their fruiting season, they are excellent for dessert purposes, while in any case they form a most welcome culinary fruit. They are in season during October and November.

Planting may take place from November to March, taking care to prepare the ground well now by deeply digging and adding some well rotted manure and rubbish from the garden bonfire. The rows may be 5ft. apart and a distance of 2ft. between the plants will be sufficient; plant so that the roots are close to the surface, for all raspberries are of a shallow rooting habit.

If planted in the autumn the canes must be cut to within 2ft. of the ground at planting time and right back almost to ground level in the spring; while spring-planted canes will, of course, require cutting to ground level when they are planted.

The routine culture of the autumn-fruiting raspberries differs somewhat from that of the summer-fruiting section. In the case of the former class, all the canes are pruned back hard to ground level every spring and the fruit is produced near the extremities of the current year's growth. When the young growths appear after pruning they should be thinned out so that only four of the most vigorous are allowed to remain. A mulching of decayed manure placed about the roots at the beginning of the summer will be found to give highly beneficial results.

One of the best varieties I can recommend for trial is the Hailsham Raspberry, a very consistent fruiter, the fruits of which are good flavoured, well coloured, large, profusely borne and luscious, while the plant itself is a good doer. Another good variety is one known as November Abundance.—T. H.

Points to Consider when Ordering Fruit Trees and Bushes.

PRIOR to placing an order for fruit trees it is necessary to estimate correctly the exact number required. All too frequently too many are ordered, and, disliking to waste the surplus, the amateur grower plants them too thickly, with disastrous results.

The approximate space required by different types of fruit trees and bushes is as follows: Apples, pears, cherries, plums, etc., grown in bush form, should be allowed 10ft. in each direction. Half-standards require 15ft. each way, and standards 20ft. or 21ft. Fan-trained trees need 15ft. of wall or trellis space, and horizontal espalier 12ft. Single cordons may be planted 2ft. apart, but those with more than one branch will require up to 5ft. of space.

Bush plants of the stronger growing varieties of currants and gooseberries should be allowed 6ft. of space in each direction; but the less vigorous kinds will only require from 4ft. to 5ft. of space. Single-stemmed cordons may be planted 12ins. or 15ins. apart.

Raspberry canes may be planted in rows 5ft. apart, and, allowing a distance of 1ft. to 15ins. between the canes.

Loganberries and the American blackberries require at least a distance of 6ft. between the clumps.

Strawberries are planted in rows 2ft. 6ins. asunder with a distance of 1ft. between the plants.

In most cases it is not advisable for the amateur to purchase "maiden"—that is, one year old—trees. By planting older trees he obtains the dual advantage of having the trees come into bearing sooner and having the foundation of the tree laid by the correct pruning of an expert. Of course, maiden trees usually transplant best, but as most reputable nurserymen transplant their young stock frequently, this is not of very great importance.

The following may be taken as suitable ages at which to purchase the various types of trees:

Standards and half-standards, four or five years old. Fans and espaliers, three or four years old. Bushes, two to three years old. Cordons, two years old.

Gooseberries and currants are best planted when two years old, and raspberry canes as young plants of the current year's growth. Newly rooted runners of strawberry plants are correct for planting.

Most important of all is to go to a reputable British nurseryman for the stock; if it is possible to inspect the trees before purchase, so much the better. So-called "cheap" trees bought in auction rooms and similar places frequently turn out dearest in the end.

When making a selection of varieties of apples, pears, plums and cherries, it must be borne in mind that certain varieties are self-sterile and will not set crops of fruit unless trees of another variety are planted close by to ensure a supply of pollen necessary for fertilisation. It is always advisable, therefore, to plant two or more varieties of these fruits in proximity, or, alternatively, to ascertain that it is a self-fertile variety which is being planted. The bush fruits are quite self-fertile and do not require interplanting with other varieties.—T. H. E.

APPLE PICKING and STORING

THE best criterion for deciding whether apples are ready to gather is the easy separation of the fruit at its junction with the spur. If the fruit requires force to sever its connection or requires to be twisted right round to remove it is not ready. A slight upward, downward or sideways turn should be all that is necessary. If the apple separates readily by this motion it is in a fit state for gathering. As a general rule early apples should be gathered as soon as they are ripe. Late apples, that is those which have to be stored to reach maturity, should be left on the tree as long as possible, but picked before the severe frosts come.

All fruits should be gathered when quite dry and on a dry day. Each apple should be picked by hand and carefully placed in a basket or other container, which has been lined with paper, wood wool or some other soft material to prevent bruising the fruit. On no account should apples be shaken from the tree if they are required for keeping purposes, and in any case, with perhaps the exception of fruit used for cider making, the practice is bad.

The gathered fruit should then be sorted out, separating the small, injured and diseased fruits from the good fruits. The good fruits may be graded according to size and, if of sufficient quantity, stored in separate trays.

To ensure preservation of the fruit a low temperature, still atmosphere and darkness are essential requirements. The room in which the apples are to be stored, if a specially constructed room is not available, should have a northern or eastern aspect, with good ventilation, yet free from draughts. The fruit should be stored in trays and a convenient size for a tray is, length, 2ft. 6ins.; width, 1ft. 6ins.; and depth, 4ins., with upright corner pieces made of wood 1in. square and 5ins. in length. The corner pieces will project 2ins. above the level of the tray. Across the ends of the box on a level with the top of the corner pieces, two pieces of wood 1in. by ½in. by 1ft. 6ins. should be placed to form handles. This arrangement permits the trays to be stored one above the other and allows plenty of space for air circulation.

The sides and ends of the trays should be made of ½in. wood, and the bottom of ⅜in. wood in three or four pieces, with cracks between them.

The bottom tray should be placed on blocks of wood 3ins. square, 3ins. deep and not directly on the floor. In a normal room, 12ft. by 12ft. by 10ft., it should be possible to arrange two rows of boxes in the centre and one row along each side, leaving the doorway free and the window side free. If this gives too many trays, the centre trays can be dispensed with.

The trays should be lined with wood wool or with paper and the apples placed in a single layer upon this lining. If the apples are graded, all of one size should be placed together.

The temperature of the fruit room should be kept steady and as near 40 degrees Fahr. as possible, for the cooler it is kept the longer the fruit will last. At first there is a sweating period, *i.e.*, a period when the apple appears to sweat by the exudation of moisture. During this period, ventilation should be the maximum available, but on the termination of the sweating period air should be admitted only when necessary, and the room kept close, with drawn blinds.

Periodically the trays should be taken down and the fruits examined. Any that show signs of rot or decay should be at once removed. It is not necessary to handle the fruit in examining them, only suspected fruits should be touched, the less handling the better. The prompt removal of decayed or diseased fruit is an essential to successful storage, as fungus spores on bad fruits are rapidly and easily disseminated and may attack sound fruits, causing them to decay. Ease of inspection and prevention of spread of disease are two reasons why fruit should be stored in single layers in flat trays, rather than in boxes or tubs.

By a careful selection of varieties it is possible to obtain dessert fruit for the table over a period stretching from the end of July to the following May. H. D.

VOL. XCI.—No. 2913. OCTOBER 1, 1927. PRICE TWOPENCE.

SELECTING ROSES FOR NEXT YEAR

SELECTING roses for planting is similar to selecting books. It depends for what purpose they are required, and they should be chosen, either on recommendation or from a personal acquaintance. Most people who cultivate roses do so for pleasure; they do not aspire to exhibiting blooms, yet not infrequently we find that from superb flowers staged at some exhibition, they jot down the names and order accordingly, sometimes to find that, when in the garden, they fall short of expectation! While there are many sorts shown which, under ordinary treatment, turn out well, it is, we think, a mistake to be guided entirely by what the exhibition table provides. The main thing the would be buyer should satisfy himself about is whether the sorts upon which he may have set his heart are "good doers" and are suitable for the district in which he resides. One of the best means of education in the art of rose growing is to visit a nursery in summer when the plants are in bloom, and see them growing in dozens of one variety. By this method one may learn a good deal, and my experience of nurserymen is that they are pleased to receive visits from prospective buyers, and to give information and advice.

For Bedding.

In the case of roses for bedding, required, possibly, for a new garden of moderate dimensions, it is better to start with two or more of one variety, rather than have a couple of dozen, say, of dissimilar sorts, as one is better able to judge of their qualities for the particular locality. Beauty of form and colour often make the strongest appeal, but those noted for fragrance ought not to be lost sight of. The peerless white blooms of Frau Karl Druschki would be infinitely more valuable did they possess perfume; yet, notwithstanding this, it is a rose which ought to be included in a collection. Fortunately, among hybrid teas one has a choice of many sweet-scented varieties, and the following list, which is given mainly for the benefit of the beginner, will enable him to select those which are noted for their beauty and sweetness too:

Betty Uprichard	*General McArthur
Golden Emblem	*Hoosier Beauty
*Ophelia	Los Angeles
Mme. Abel Chatenay	Mrs. Henry Morse.
Mabel Morse	*Richmond
*Caroline Testout.	Margaret Dickson
*Isobel (a charming single carmine of vigorous growth, delightful for cutting)	Hamill
	Gorgeous
	*Rev. F. Page Roberts
Emma Wright	Mme. Herriott
	W. F. Dreer.

Although the hybrid perpetuals belong to a race of roses very limited, yet a few of them are worth inclusion. Frau Karl Druschki has been mentioned. To this may be added *Hugh Dickson, a brilliant crimson and vigorous grower, and notable for its fragrance. Mrs. John Laing, a rosy pink, is also very sweet-scented.

All the foregoing have proved themselves suitable for general growing, and, given ordinary care in the preparation of the ground and planting, seldom fail to give satisfaction. The question is sometimes asked what are the dependable roses for growing in a cold, and perhaps bleak quarter, and the sorts for such a position among the short selection are denoted thus (*).

Climbers.

Much attention is being given to climbers to-day. They are brought into use for covering walls and fences; for pergolas and arches, and to block out unsightly objects. The Wichuraianas take the lead. Of these it may be said that the bulk of them are so strong and vigorous that one need not have any hesitation in planting them in an exposed position in a garden. There is no difficulty in choosing a variety of colours, as the following will illustrate:

American Pillar (single pink)
Hiawatha (single crimson)
Albéric Barbier (creamy white)
Emily Gray (golden yellow)
Evangeline (single white, tipped pink)
Leontine Gervaise (coppery buds, opening to rosy salmon)
Excelsa (crimson scarlet)
Troubadour (deep crimson red)
Minnehaha (rose pink).

Let not the intending planter of climbing roses forget the climbing hybrid teas that, every year, are becoming recognised more and give their flowers over a long period.

These embrace many well known sorts (included among them being teas and noisettes), such as Caroline Testout, Sunburst, W. A. Richardson, La France, Lady Ashtown, General McArthur, Reine Marie Henriette (the red Gloire). They are very sturdy and will do well in most positions. One of the very best hybrid teas among the climbers, blooms of which figured at not a few of the principal shows during the past season, is Mermaid. Flowers are of a sulphur yellow, with amber stamens and attractive foliage. It blooms for a considerable time, and makes a good drapery for either a wall or fence or pergola where it can festoon. It is a rose that will be seen more often in future. The flowers are single and very attractive.

This Week's Work

For Gardens in the South and Midlands.

Plant hyacinths, Dutch and Spanish irises, and daffodils in beds.
Transplant seedling biennials and perennials.
Lift and store beetroots, carrots and onions.
Put grease bands round fruit trees.
Make an autumn sowing of sweet peas in the open ground.
Prepare ground for rose or shrub borders.
Gather and store late varieties of apples and pears.
Make preparations for replanting the herbaceous border.
Finish taking cuttings of calceolarias, violas, antirrhinums and pentstemons.

This Week's Work

For Gardens in Scotland and the North.

Start digging vacant ground.
Transplant wallflowers and Canterbury bells in permanent quarters.
Lift and store carrots and beetroot.
Insert cuttings of calceolarias and pentstemons in cold frames.
Divide and replant herbaceous peonies.
Continue planting daffodils and hyacinths.
Propagate phloxes by cuttings of non-flowering shoots.
Clean and oil garden tools before putting them away for winter.
Store, burn or dig in fallen leaves.
An autumn sowing of sweet peas may still be made.
Order roses to fill up vacancies in beds.

AUTUMN WORK IN THE BORDER

Now is the time to give thought to the management and replenishment of the herbaceous border. Whether a stereotyped plan is followed or one carried out according to personal tastes, the work provides much interest combined with instruction. The following article gives a few hints on what to aim at in the making and renovation of a border.

WHEN one reflects on the number and variety of plants which go to constitute what we term the herbaceous border, one cannot but be struck with the elasticity which is allowed in the selection of the inmates and in their placing and general arrangement. Borders are designed and laid out in a countless number of different ways, according to the purpose for which they are desired. It may be a spring, summer or autumn border. It may exist principally for a vivid and harmonious colour display over a short period, such as a blue border; or again, it may be arranged and its occupants so selected that the ideal border is obtained—that which supplies an array of bloom of all colours, size and form from the first weeks in May till the dawn of October. In such a border, the choice of plants must be a wide one. Hardy herbaceous perennials will probably predominate; while there will be the necessary addition of a few annuals, along with a number of more tender plants. Not only, however, should the actual plants comprising the border be thought of; attention to the background is just as important. Without a suitable background the actual border loses much of its beauty, while, if present, the appearance of the bright and gaily coloured ingredients is greatly enhanced. With the approach of autumn, gardening duties gradually increase till the pressure reaches a height by the end of October or November, and it is always well that the work should commence early on. During this month the gardener should carry out all renovations in the shape of transplanting all plants, including shrubs, division of existing plants and in the rearranging of his borders. With early planting the individuals removed are enabled to establish themselves more quickly and surely before the approach of winter than those planted later on. All the necessary changes which have been decided on during the early summer months to improve the colour scheme or the design of the border should be carried out as soon as possible. It may be the intention of the owner to try out new plants, and if so, now is the time to scan all the many catalogues. Amateurs cannot go far wrong if they but follow the instructions given in these handy brochures. Once all the material has been collected, the planning and placing can then be undertaken. This is entirely a matter of personal taste, depending on the degree of contrasting effects which one wishes. It cannot, however, be too often reiterated that the best effects are obtained by planting in masses or broad drifts. Blocks of sharp colour are then the cynosure of all eyes when hemmed in by two darker patches. By this method, also, the individuality of the plants is shown to best advantage, and when large-sized flowers appear, their elegance, size and form can be fully appreciated, and one finds enjoyment doubly increased by a visit to a border such as this. The occupants should have a position calculated to show them each off to distinct advantage, while at the same time they should harmonise with their environment.

A WELL DESIGNED BORDER WHERE THE PLANTING HAS BEEN CARRIED OUT EFFECTIVELY. *Each plant has been grouped in bold clumps, each bearing a relation to the other with regard to to height and colour, so that there is nothing harsh or incongruous in the general scheme.*

Now as to the actual inmates of the border. It is a difficult task to know where to begin and where to end in the matter of a selection of plants. To commence with are those which on no account should be omitted, such as phloxes, which probably rank first as the chief ingredient in all borders. They are eminently suited for the purpose, with their wealth and variety of colour and in the large trusses of well formed and shapely flowers. During the last few years these flowers have been improved enormously, and the varieties and their names are now legion, and certainly all tastes are catered for. It is impossible to mention more than a few varieties of the several scores that exist, but the following can be recommended: Frau A. Buchner and La Neige are good whites, Elizabeth Campbell a good pink with a white centre, Selma a fine tall-growing pink, Baron von Dedem scarlet flushed with orange, Iris a violet-blue, and Antonin Mercie with soft lavender blue flowers and a white eye which is particularly effective. The representatives of the composite family, such as rudbeckias, heleniums, gaillardias, marigolds and sunflowers, can be conveniently grouped together. These thrive in the majority of garden soils and are among the showiest of summer border flowers. When planted in the mass the most dazzling sheets of brilliant colour are produced during the summer and autumn months. They have the additional merit, also, of lasting a long time, and are suited for house decoration. The popularity of the dahlia as a border flower has returned during these last few years and certainly its extended cultivation is fully deserved. With its many shades of colour and its great variety of forms, both as regard height and sizes, the dahlia fits into any scheme with the greatest of ease. The dwarf single and mignon types are especially suited for a corner in the front of the border, while the taller decorative and cactus-flowered varieties call for a place in the rear ranks. If a touch of blue is desired, delphiniums cannot be surpassed. Not only do they provide a colour which is too often lacking in the garden, but they serve, when used as a background, to throw up their more dwarf neighbours into relief. Their handsome appearance, with their elegant spikes of clear blues and mauves, renders them desirable subjects. There are so many fine varieties on the market nowadays that it is difficult to make a choice. The following, however, can all be recommended: Blue Boy, deep blue single with a white eye; King Bladud, double and of a fine cobalt blue; King of Delphiniums, gentian blue flushed with plum; James William Kelway, an improvement on the foregoing; the well known Rev. W. Wilks, of a rich purple; the soft creamy white Beauty of Langport; the bright blue and violet, Lloyd George; Millicent Blackmore, blue and mauve with large black centre; and Nora Ferguson, semi-double, pale blue blended with soft pink. Of the Wrexham strain, where the spikes are longer and tapering, among the best are Coquette, violet with blue shading and a bee-like eye; Joy Bells, aptly named, for it has bell-shaped pips of a deep rosy mauve; Monarch of Wales, with guard petals of a bright blue and inner petals of a rosy mauve; and Violet Queen, deep violet margined with mauve. Michaelmas daisies are valuable for their late-flowering propensities and should be included. Antirrhinums and pentstemons are useful for planting between taller-growing subjects and provide a wealth and variety of handsome spikes of attractive flowers. Many campanulas, such as lactiflora, should find a place. They supply the more delicate tones so necessary to relieve the brighter shades. Patches of flame colour are obtainable by the judicious planting of clumps of red hot pokers. I say "judicious" advisedly, as, if discretion is not used, the result is apt to be overwhelming. Along the edge of the border more dwarf subjects can be employed, such as the brilliant double alyssums, the double white arabis, and the attractive candytufts. No hardy border is complete without irises. They seldom clash with the other occupants, and patches of them in their delicate shades of colour impart tone and form during the early summer months. Gladioli are most useful for providing colour in late summer.

Many shrubs and climbing plants can be utilised to distinct advantage if employed in border plantings. A definite association

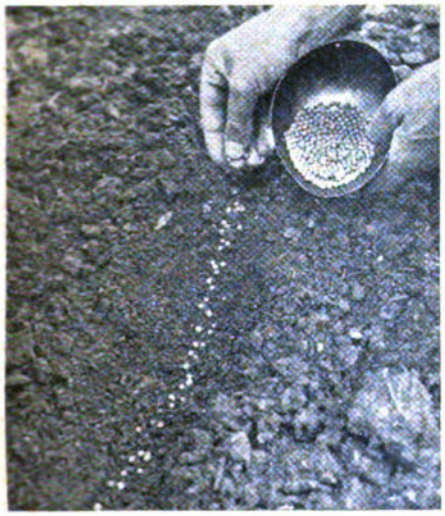
Digitized by Google

should be aimed at between the foreground and the shrubby background. Such shrubs as ceanothus look well with clematis and delphiniums. Hydrangeas are also useful and can be put to many purposes ; while shrubby veronicas are excellent in any arrangement. Silvery leaved shrubs should be planted, if space permits. They greatly enhance the appearance of all the yellow-flowered varieties. Sufficient has been said to show that the herbaceous border need not be stereotyped in its composition. Personal taste should be given free play, and the results are almost certain to be pleasant and satisfactory. But whether you prefer a border all of one colour or one of varied tints, so much has been done recently to improve the herbaceous border that plants are in existence to satisfy every taste.

SWEET PEAS FOR NEXT YEAR'S BLOOMING

Sweet Peas may either be sown now or in the spring. The following article conclusively shows that the best results are to be obtained if autumn sowing is undertaken. In this year's sweet pea trials it was emphasised that sowings should be carried out before the middle of October both in the north and south. Autumn sowing provides plants of a more robust constitution and which give blooms of a finer quality than is generally the case with those sown in spring.

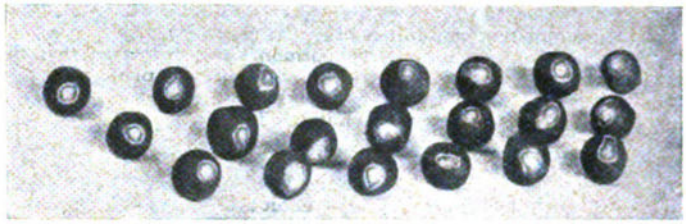
SWEET PEAS, like many other hardy annuals, almost invariably produce the best results when sown in the autumn. Each succeeding season the proportion of sweet pea seeds sown before Christmas to those sown afterwards steadily increases, as the advantages of the former method become more widely known. Comparing average results, we find that autumn-sown plants not only flower earlier, but often continue to yield good blooms after spring-sown plants have finished. The latter are never so robust at any stage of their growth, rarely give such good quality flowers, and are less able to withstand adverse weather conditions. Apart from this, autumn-sown plants undoubtedly are better fitted, through their stronger, hardier constitutions and more extensive root system, to combat the few ills with which sweet peas are liable to become afflicted.



SOWN IN DRILLS ABOUT TWO OR THREE INCHES DEEP IN THE OPEN GROUND.
Seeds may be sown fairly thickly and the seedlings afterwards thinned if found necessary. The work must be undertaken during the next fortnight for successful results.

It does not matter whether one intends to grow them on the "single-stem" or "cordon" system, or just in the ordinary natural manner, autumn sowing is certainly best, and I strongly advise all growers to sow at least some of their sweet peas before the end of October.

There are two methods of sowing in the autumn, the first being the usual procedure of market growers of cut blooms, namely, in the open ground where the plants are to flower. This is quite simple and comparatively safe, for the plants pull through the winter nine seasons out of ten. Well drained soil is to be preferred, and the position (chosen in advance) should be in an open situation unshaded by trees or buildings. Prepare the soil well either digging it over deeply, turning in a liberal dressing of well decayed manue, or, better still, bastard trench it to a depth of 2ft. to 2½ft., well mixing in animal manure and bone meal in the lower layer. Towards the end of September or early October (according to locality) make drills with a hoe about 2ins. deep, sowing the seeds fairly thickly to allow for possible losses by pests or the weather. If thought necessary the plants may be thinned out in the spring. After covering in the seeds, dress the surface of the row with soot, then leave the plants to take their chance. It will afford them no little protection if short twigs are placed against them about the end of November. Often enough the inexperienced grower will think that he has lost all his sweet peas, but it is surprising how quickly they will recover at the first sign of warm weather even if they have to all appearances been destroyed by frost. Try a small row of mixed Spencer varieties sown in this way, the loss will be immaterial should they fail, for a really good mixture costs no more than 1s. per ounce, and this quantity will be ample for an 8yd. row.



SEEDS READY FOR SOWING.
In order to assist germination of black seeded varieties the seed should be chipped in this manner before sowing.

The second method, practised by nearly all exhibitors, is that of sowing the seeds in pots in a cold frame. It is much more economical and much less risky than sowing outdoors. In the first place, the seedlings are quite under the grower's control and it is a simple matter to give them protection from the weather when necessary. Pests, too, which might cause serious losses in the open ground, birds, slugs, mice, etc., may easily be guarded against. Pots of any size between 3in. and 6in. diameter at the top are suitable. Crock their bottoms and fill them to within half an inch of the rims with soil. There is no need to bother about a specially prepared potting soil, for any ordinary garden soil will do if it is fairly porous. Th addition of silver sand will lighten a heavy or "clingy" soil, and a rich compost is quite unnecessary. Vary the number of seeds in each pot according to its size, roughly allowing 2 sq. ins. of surface space to each seedling. Then fill the pots to their rims with soil and water at once if this is on the dry side, avoiding a further watering, if possible, until the seedlings appear through the surface. Correctly label each pot or batch of pots with the names of the varieties and then plunge them to their rims in the frame with soil, ashes, peat or fibre. This latter not only gives the roots protection from the frost, but conserves moisture. As soon as the young plants make their appearance remove the glass frame lights entirely and never replace them except during very frosty or wet weather. Throughout the winter grow the seedlings along slowly and very hardily, for this is the one and only way to obtain strong, healthy plants for transplanting in the spring. The frame should face the south and should not be shaded, or spindly drawn-up specimens may result. As soon as the pots are in position in the frame it is a wise precaution to set a few "break-back" traps for mice, while later on, if birds commence to nip out the tender tips of the plants, check their depredations by throwing fish netting all over the frame or by stretching strands of black cotton just above the seedlings. Water sparingly, and insert a few twigs to hold them upright when they are about 3ins. high. It will do no harm to pinch out their extreme growing

SOWING SWEET PEAS IN POTS.
About five seeds are necessary to fill a five inch pot. After sowing, the pots can be filled almost to the rim with soil and placed in a cold frame or small greenhouse.

Digitized by Google

tips when they have made three pairs of leaves, but this is not really necessary if they are sturdy, for then they will naturally throw out strong basal side shoots without this treatment. Many successful growers, however, always "pinch out" to make certain.

The best time to sow in pots in a cold frame varies with the locality from the last week in September in Scotland to the last week in October in the south. Mid-October is a good average date.

AN AUTUMN AND A SPRING SOWN PLANT. *The larger specimen was sown in October while the smaller was sown in February. The difference in size of root systems can be clearly seen. The former has been pinched and has thrown out basal side shoots.*

Although one may procure the best seeds it is possible to obtain, an uneven germination is sometimes experienced with black-seeded varieties. A proportion of these will often remain dormant in the soil for weeks, quite impervious to moisture unless their hard seed-coats are "chipped." This operation is simply the removal of a very small portion of the seed-coat with a sharp penknife or file on the side away from the "eye." On the other hand, white-seeded varieties as a general rule have very thin seed-coats and sometimes rot during germination if this is protracted by cold weather or if the potting soil is too moist. It is quite a good plan to sow white seeds in a thin layer of silver sand to avoid this.

For the benefit of those readers who may be unfamiliar with the great number of varieties I will give an inexpensive selection of really first-class kinds, suitable alike for exhibition purposes or for ordinary garden and home decoration, indicating with an asterisk the black-seeded ones which may need "chipping." Model, Avalanche and Constance Hinton, white; Ivory Picture, old ivory; Powerscourt, lavender-lilac; Mermaid and Gleneagles, blue-lavender; *Sybil Henshaw and *Charity, crimson; What Joy and Matchless, cream; Chieftain and Royal Mauve, mauve; *Warrior and *The Sultan, maroon; *Youth, picotee; Picture, deep cream-pink; George Shawyer, orange-salmon; Mammoth, orange-scarlet; Charming, Centaur and Coralline, cerise; *Lilac Queen, lilac; Dainty Maid, blush; *Sunset, rose; Twinkles, striped; Gold Crest, salmon; Venus and Mary Pickford, light cream-pink; Olympia, Purple Monarch and Royal Purple, purple; Mrs. Horace Wright and Queen of Roumania, flushed; Grenadier and 2LO, scarlet-cerise; Mrs. Tom Jones and Heavenly Blue, mid-blue; Magnet, W. J. Unwin and Miss California, salmon cream-pink; Renown, carmine; Wizard, Colorado and Royal Sovereign, orange; *Hebe, *Supreme and Mrs. Chas. W. J. Unwin, pink. C. H. A. S.

STONE PATHS for BEAUTY and UTILITY

A further article on the making of stone paths by one of our readers who has found the method, herewith described, to work out extremely well in practice. This is a variation of the methods already described by former contributors in THE GARDEN, *in the issues of March 26th and June 18th.*

A VERY "difficult" narrow passage, along the north side of a semi-detached house (built on Essex clay), leading to the back door and garden, was for three winters a hard problem. First of all sand, then ashes from a boiler fire, hoggin, and ordinary crazy paving were tried in turn; but the path was always more or less of a quagmire after a shower of rain and practically during the whole winter, with results to linoleum and carpets which may be left to the imagination! This has now been "paved" in the following manner, and for the first time can be kept both firm and clean.

The same proportions as previously recommended, 4 parts of sand to 1 of cement, were used; but a variation was introduced by using 1 part of cement to 2 each of sand and ashes, the latter collected from a Beeston boiler. This not only effects a certain amount of economy (because where the sand has to be brought a considerable distance and then wheeled in the cost soon mounts up), but results in a mixture which is easier to handle, ashes being lighter than sand, and forms a better "mass," being in fact a form of concrete. The cement and sand were first of all well mixed together and reduced by means of water to a slush. The ashes were then added without distinction of size (they are the result of burning a 50-50 mixture of anthracite "walnuts" and small breeze, and consist partly of "dust" and partly of clinkers), and the whole thing was turned over and over until it reached the consistency of fairly stiff paste.

The ground was prepared in the usual manner—in the case of the passage, the house on one side and the border fence on the other provided the containing framework on two sides—and wetted. The concrete was then shovelled on, roughly levelled with the back of the shovel and a piece of straight-edged board, and finally worked quite smooth on the surface with an ordinary plasterer's trowel, care being taken to submerge any bits of clinker that came to the surface. The passage is more than 30ft. long and was done during week-ends in 6ft. to 7ft. lengths at a time, a lath of wood being placed across it and pushed up against the semi-liquid concrete as soon as the section under treatment had been laid down, thus retaining it in position until it was set, and preventing spreading with consequent loss of uniform thickness.

Normally, the concrete, after the smoothing process, was covered with strips of three-ply wood (ordinary planks will suffice, but their greater weight is apt to make indentations), which serve the double purpose of protecting the surface from weather (and cats and dogs) and enabling it to be walked over within two or three hours of being laid. It was then left for forty-eight hours. At the end of that time the protecting boards were removed and, with the aid of an old chisel (broken off at about an inch from the handle) or any convenient straight-edge, lines were scored deeply in the surface, but *not* to the full depth, of the partly hardened concrete. These lines can be either parallel and straight, with cross lines at different intervals in alternate lengths, thus giving the effect of rectangular paving, or in any desired directions, thus giving the effect of crazy paving. The loose material thus scraped out was brushed away with an ordinary yard broom which had the quite charming effect of leaving the edges of the cuts a little rough and uneven, thus completing the illusion.

Drainage has been provided by making small holes about 1in. in diameter every here and there at the intersections of the cross-cuts. This can be easily done with any sharp-pointed stick before the concrete is quite set. In the pavement above described, the sticks were driven down about 3ft. into the sub-soil and withdrawn, and lengths of ordinary brass casement rod inserted. Two longitudinal gulleys were also left when laying the concrete, sloping into drains.

Finally, when the concrete appeared to be fairly well set (about five to seven days after laying, according to the weather), half a dozen trowelfuls of cement were put into a bucket and mixed with plain water until it reached the consistency of Devonshire cream. This was then "slapped" on to the surface of the concrete by means of a 4in. flat distempering brush, and when dry—that is to say, from twelve to twenty-four hours later—gives the appearance of old weathered stone.

Two hints may be useful in connection with this final process: (1) keep your liquid cement well stirred up all the time—it settles very quickly; (2) use the brush edge-wise when applying cement to the channels cut with the chisel. The latter should be done first, and then the flat portions treated with the broadside of the brush, inwards (*i.e.*, *away*) from the indentations. This avoids the latter filling up.

A couple of pedestals for sundials or vases have been manufactured by exactly the same process, and—apart from the design, which is admittedly crude and amateurish—are quite efficient. In this case, however, the concrete naturally takes much longer to set, especially in the upright portion. Two hints may also be of use here: (1) do your casting on the spot where the ornament is eventually to stand; as these things are very heavy. (2) Make the container-forms for the upright (column) portion strong, and lash them round the outside every 6ins. with strong knotted box-cord; otherwise, the pressure of the semi-liquid concrete, which in this case has to be poured into the top of the form, will burst it apart before it has time to set. H. E. T.

FOLIAGE EFFECTS IN THE ROCKERY

IN many places the rock garden is a neglected feature during nearly half the year, and only visited at that time by the keen enthusiast or the man who is paid to look after it. When the glory of spring and early summer has departed there is little for the casual visitor until the call of the early-flowering bulbs and cushion saxifrages again becomes urgent in the spring. But when plenty of plants with evergreen foliage are used, and these are properly arranged in bold contrasting masses or clumps, the rock garden becomes interesting and beautiful all the year round. And in a land where much of the colouring is grey and green during a long season it is well to educate our vision to see beauty in quiet things.

To get the best foliage effects during the dull season it is desirable to plant in bold masses, and to get strongly contrasting colours in juxtaposition. It need hardly be said that pretty silvery or grey-green foliage looks much brighter when contrasted with dark green or bronze green. A certain portion of rock showing gives another interesting contrast, and it is always desirable to keep the plants from entirely hiding the rocks. Plants hanging down the rocks and partly covering them, or little creeping subjects ascending over them, is quite another question, and these should be encouraged in reason. There is a happy mean to be attained in this business, and a rock garden should show some order and arrangement, and yet not look as if it has been groomed as well as gardenered.

To mention a few of the plants with silvery evergreen foliage, there are the encrusted saxifrages, and it matters little if these have large or small rosettes provided there are enough of them in one place. For foliage effects those having the greatest amount of silvery bloom on them should be grown. Several of the Aizoon type of saxifrage are beautifully silvered, notably S. aizoides, S. Aizoon, S. cochlearis, S. crustata, S. lingulata and S. paradoxa.

For a place near the top there are several helianthemums with grey foliage, some of the best being H. apenninum, H. incanum, H. præcox, H. Golden Queen and H. White Queen. When quite happy these grow into tiny bushes, and in addition to their other uses help to redeeem the rock garden from monotony in the size of the plants.

Some of the achilleas, A. argentea, A. Clavennæ, A. Huteri and A. umbellata, are quite silvery when well grown.

The acænas are also very pretty in winter, and the New Zealand variety puts on quite a bronzy shade of colour. The common santolina is not to be despised in a large garden, for the foliage is very pleasing, and it can easily be cut back in the spring if it shows signs of taking up too much space. The dwarfer kind, S. incana nana, is more suitable for small gardens.

Thymus lanuginosus makes a delightful patch of silvery grey, and is happiest and seen at its best when planted so that it can droop over a rock face. Other thymes are capable of giving a nice patch of deep green, and the shrubbier silver and gold kinds are useful in this connection.

Those joyous weeds the antennarias, if grown in poor stony soil, make pretty silvery carpets, and are dwarf enough to have more important things rising among them. And there are several sedums, veronicas and cerastiums that will be helpful, so also will Raoulia australis, if you can get it to spread into a good carpet.

Any attempt at naming the evergreen things contrasting well with the silvery subjects mentioned above would result in a very long list, but a few of my own favourites are the mossy saxifrages, the green thymes, sempervivums, the larger Aizoon saxifrages, the smaller armerias, Acantholimon glumaceum and the green-leaved sedums. Pentstemon Scouleri looks like a dainty little shrub in wintertime, with dark green foliage.

Things giving bronze and purple shades are not so plentiful, but Ajuga reptans purpurea gives a nice patch of beetroot colour. The variegated kind is worth using, and when in good form it shows a lot of white. The Megasea saxifrages often put on a good bronzy colour, and one mossy kind, S. decipiens, turns nearly crimson in the autumn. Sedum spathulifolium purpurea is delightful at all times, the purple foliage being touched with a silvery bloom. The typical plant, S. spathulifolium, should be grown for its silvery effect. Both are sometimes a little difficult in the winter, but not when put on a very stony soil, something after the manner of a moraine. Limestone helps to bring out their beautiful colour.

A few of the charming cushion saxifrages, especially S. apiculata and S. a. alba, are quite free growing, and soon make a good carpet and, in addition to the cheerful foliage, they provide very early flowers. The autumn-flowering cyclamen send up marbled foliage that is effective all the winter, especially when the plants have a mossy creeper beneath them.

Some of the arenarias are beautiful all the year round, and A. balearica keeps growing until hard frost intervenes. To see it at its best it should be given a rocky place that is cool and shady. Arenaria cæspitosa is capable of making a rounded cushion 2ft. or 3ft. across, but it does not like damp soil, and I have found it at its best when planted in a little heap of broken rock with just enough soil to start it. The golden variety, A. c. aurea, is rather more difficult to manage, but it is capable of giving a very bright bit of colour all the winter.

The sempervivums deserve note in this connection, for they put on varying shades of green, purple and bronze as the foliage ripens, and all the cobweb varieties look well clustered among the rocks.

The little evergreen mountain trees and shrubs capable of giving such relief to the large rock garden should not be forgotten, but their high price is against them and they are not needed in the small rock garden. Most people, myself included, desire that their rock garden should be a comparatively inexpensive hobby.

It may be thought that planting drifts, large pockets or ledges for foliage effects is expensive work, but this is by no means the case when one has acquired a moderate stock of plants. One little encrusted saxifrage planted in the spring becomes a dozen or more by the autumn, and if these are divided in September or early October and planted from 3ins. to 5ins. apart, according to the size of the rosettes, they will soon give the desired effect. Little pieces of mossy saxifrage, sedum and sempervivum dibbled in in the same way soon become cushioned masses. Everything becomes stronger by this dividing, and the plants are likely to flower much better the next season. It is often desirable to mound slightly a flat pocket without a good slope to it, for so doing makes the new planting far more effective. Any of these foliage plants if planted now will give a good display by next autumn.

T. H. W.

ROUNDED CUSHIONS OF ARENARIA CÆSPITOSA.

This sandwort, together with the decorative cobweb varieties of house leeks, make a happy and effective foliage group in the rockery. The former plant is especially useful for fringing the rockery paths.

THE BUSY MAN'S PAGE

Reminders for October.

COMPLETE the gathering of the late varieties of apples, pears and plums.

Remove old and useless fruit trees and bushes and prepare the ground for replanting. In many cases it is a good plan to change the soil, if possible working in some good turfy loam. Bear in mind that lime is necessary for stone fruits, and if it is not present it should be added.

Where root pruning is carried out, the present month is a good time to begin.

At the end of the month insert cuttings of currants and gooseberries.

Remember that the winter moth is now active, and grease-band the fruit trees at a height of about 3ft. from the ground.

Cut down the stems of asparagus, and the soil over the crowns may be forked down level, finally adding a good mulching of well decayed manure.

Roots of carrots, parsnips and beet may be lifted as required, but, unless it is desired to clear the ground, there is no particular object in raising the whole crop just yet. In fact, parsnips are all the better for being left in the soil until wanted for use.

Cabbage plants may still be put in, and onions should be stored in dry, frost-proof places.

Earth-up celery on fine dry days.

Transplant young cauliflowers in frames and bend over the heads of those in the open to protect from frost.

To lift beetroots and carrots a fork or spade should be used, thrusting it into the ground a few inches from the root.

The method of arranging beetroot in a cool shed, cellar or out-of-doors.

Any potatoes that have not been lifted should now be taken up.

Keep a sharp look-out for weeds, which will often grow vigorously in the autumn.

If the weather is dry, use the hoe between growing crops.

In the flower garden clear away all dead vegetation and place this on the compost heap so that it may decay into useful material.

All the spring-flowering bulbs may be planted, choosing dry weather for the business. Also plant daisies, wallflowers, pansies, primroses, etc.

Herbaceous perennials may be lifted and the roots divided, but, in order to prevent confusion, everything should be carefully labelled.

Cuttings of ripened shoots of roses may be inserted this month, and also slips of many ornamental trees and shrubs will root well.

Violets may be planted in gritty soil in frames for winter flowering.

In greenhouse and frames continue free ventilation, and do not close too early at night or a very damp atmosphere will be the result. Any watering that is needful should be carried out in the morning.

Complete the potting of any bulbs that are to be brought into early flower and bring all the indoor chrysanthemums under cover.

Lifting and Storing Beetroots and Carrots.

BEETROOTS should be lifted as soon as the leaves are touched with frost, and this may be an accomplished fact at any date after the early days of October. No time should be lost in preparing the necessary storing accommodation, so that the roots may have protection when required.

There are many places where beetroots and carrots may be stored quite successfully. A cool shed will answer the purpose admirably. Cellars are better, however, or failing these, any outhouse where, with a slight covering, the beetroots in particular may be protected against frosts. Those who have no such accommodation, however, may very easily make a clamp wherein these roots may have the necessary protection. On no account should the roots be pulled out of the ground. Beetroots are very tender, and unless they are lifted intact, the tap root may be broken or bruised. Bleeding will be the result, and as a consequence the deep colouring, which is an essential part of the beetroot, will be spoilt. When lifting beetroot preference should be given to the use of a spade, as a fork may slip or break through the soil and pierce or damage the roots.

Carrots of the stump-rooted and intermediate types may be pulled up with little or no trouble, but the long-rooted kinds are lifted more satisfactorily when a spade is used. Beetroots after lifting should have their leaves twisted off a few inches above the crowns. On no account should the leaf-stalks be cut through, as this causes bleeding. In the case of carrots, cut off the tops close to the crown.

If the roots are stored in a shed, cellar or outhouse, first place a layer of sand on the floor, and then arrange them with their crowns facing outwards. Cover each successive layer with a layer of sand, and continue in this fashion until all the roots have been properly dealt with. If the roots are stored against the walls, arrange them as just described; but when they are placed in other positions, arrange them in the manner shown in the illustration.

When making a clamp outdoors—which is a most convenient method of storing most roots—place them in a circular heap in layers, still observing the rule of keeping the crowns pointing outwards. A clamp of beetroots outdoors when ready for the final covering is also illustrated. Finally, cover the clamp or mound with straw, bracken, or any other material that will answer the purpose of

A small clamp of beetroot arranged ready for covering with straw and earth.

The clamp completed for the winter.

preserving the roots against frost, and complete the operation by digging a trench round the clamp about 1ft. or 18ins. in diameter, utilise the soil thus removed to cover the clamp, and in this way render it frostproof. By these means the roots will be maintained high and dry above the ground-level. Six inches to 9ins. covering of soil suffices to exclude frost in most localities, and if the soil is made firm by using the back of a spade, rain is carried off quite successfully.

Those Untidy Rambler Roses.

FEW kinds of plants become more untidy in the course of the summer than rambler roses. If some of the shoots of these roses are to be inserted as cuttings they should be selected from firm, not very sappy, unripe wood. Such cuttings may vary in length from 10ins. to 14ins. Quite half the full length of stem should be inserted in the trench and some coarse sand placed round the base of each one. Make the soil, which is replaced, very firm by treading, then apply water freely. The best border for these cuttings is one facing the north—on the north side of a wall or fence, but not in a border filled with the roots of trees or hedge plants. Practically, all the old wood should be cut out, three or four strong shoots of the current year's growth being retained and loosely tied into position. The extreme tips of these shoots must be cut off, then the ramblers will be neat and out-of-the-way during the whole of the winter. Only one little matter will call for attention in November, the surface mulching of the plants with half-rotted manure and a coating of ordinary soil as a finish.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

What is an Ideal Pergola?

IN the gardens near Rome, Florence and Naples, there are excellent examples of the pergola, as the creeper-shaded walk is called. They are ornate structures, the supports of which are massive columns of stone, round which wistaria, Banksian roses and Passion flowers are trained to form cool retreats on hot days. The idea has become exceedingly popular in this country, especially as a means of training roses and clematis. But there are several points which should be borne in mind when erecting a pergola. First, our climate is less sunny than that of Italy, and a densely shaded walk is depressing in wet and cloudy weather. The pillars, therefore, should be sufficiently wide apart to allow light and sun, to a certain extent, to reach the path. The second vital consideration is the size of the pergola, which should be proportionate to the size of the garden. The example shown in the illustration is from a garden at Surbiton. It has dignity and proportion, and it *leads somewhere*, in this case to a well kept lawn. Which brings us to the third principle in the construction of an ideal pergola. It should divide one distinct portion of the garden from another, it should not shut off a line of view, nor should it be placed near big trees. In structure it should be simple. Straight planed square timber is better than unpeeled larch poles. Peeled poles are suitable if they are given a good coat of creosote a few weeks before any planting is done.

A danger to guard against is flimsiness. When larch poles are used, this is avoided by putting two together about a foot apart. A pergola need not be long drawn out as is usual along paths, it may take the form of a square for the terrace, wherein meals may be served in clement weather. Or it may be circular or semi-circular according to the garden design. During the erection of the pergola, thought should be given to the planting, which will be done later. Be sure to ram back the clay before you fill in the soil. The excavations can be extended round the site of each climber, so that the bottom soil can be thoroughly broken up. Allow the soil to settle and creosoted timber to dry for a few weeks before doing any planting.

New Lawns.

A WELL kept lawn is always pleasant to look upon, and particularly so in towns where the sight of green fields is missing. Green is a colour with which any and every colour of flower harmonises, hence a lawn is an admirable foreground for a flower border. Early autumn is a good time to sow new lawns or to repair old ones. The drought of early summer causes many bare patches to appear on lawns and now is the time to repair the damage. It is not necessary to dig the bare patch. Simply prick it over with the points of the fork and then rake the surface. Sprinkle grass seed over and cover it with fine soil. Make this smooth with the back of the spade or with a light roller and protect it from birds until it has begun to grow. A new lawn, or a resown patch, should not be walked on until the grass is 2ins. high.

Where a new lawn is to be made, the soil must be deeply dug, at the same time removing all stones, bricks, weeds and rubbish. If the soil is poor, a dressing of manure should be worked in. Fowl manure is excellent for lawns, so also is soot or flue dust. Should the soil be very stony, the top layer must be passed through a half-inch meshed sieve. The sifted stones can be buried in the trench as the digging proceeds, and a little of the sifted soil should be put on one side for covering the seed. After digging, rake the surface level (a piece of straight board is useful for levelling purposes), and roll it once. After this rolling, hollows will show themselves, and the rake must again be used to level the surface. Scatter the grass seed evenly on the surface. An ounce to a square yard is sufficient, but if you desire a thick lawn immediately, 2 oz. can be used. Cover the seed lightly with the sifted soil reserved for the purpose, and again run the roller over the surface. If only a small patch of grass is sown, the back of the spade, or a piece of flat board, will do instead of a roller to make the surface firm. Birds can be kept off while the seed germinates by stretching black cotton across attached to small wooden pegs.

It is essential to sow when the soil is dry enough not to cling to the tools. Another important thing is to buy good seed. The soil is warm, and the seed should germinate very quickly, so that before the winter comes, you should have a fine green lawn to cheer the outlook on dull days. No cutting will be required until next season. Lawns sown in autumn are less likely to be troubled with weeds than those sown in the spring.

OCTOBER IN THE TOWN GARDEN.

WHAT TO DO THIS MONTH.

1. *Insert cuttings of calceolarias in cold frames.*
2. *Clear away withered annuals, fill up the blank spaces with seedling forget-me-nots, wallflowers, honesty, Canterbury bells, etc.*
3. *Lift all summer bedding plants and remove them to their winter quarters.*
4. *Finish bulb planting as soon as possible.*
5. *Plant out double daisies, pinks, arabis, aubrietias, violas, etc., on border edgings.*
6. *Renovate herbaceous borders. Lift and divide where necessary, except in inner town districts, where division should be left until spring.*
7. *Divide and replant herbaceous peonies.*
8. *Put grease bands on fruit trees.*
9. *Remove raspberry suckers and plant them out to form fresh plantations.*
10. *Cut down asparagus stems, top-dress the beds with manure. Lift and store beet, carrots and horse radish.*
11. *Plant out cabbages. Earth up celery and leeks. Lift, dry and store onions. Plant out winter lettuce.*
12. *Watch bulbs planted in fibre and remove gradually to light when the growth commences. Water moderately.*
13. *Order fertilisers, soil fumigants and lime for winter digging.*
14. *Renew faded labels on herbaceous plants before cutting away the tops.*

A SIMPLY DESIGNED AND WELL BUILT PERGOLA IN A SMALL SUBURBAN GARDEN. *Not only does it add to the appearance of the garden but it serves a useful purpose. It leads to a cool green lawn and provides a refreshing vista in limited space.*

Bulbs in Bowls.

"OUT of sight, out of mind," is a saying which we should remember when growing bulbs in bowls. When they are put away in a dark place to encourage root formation, we are apt to forget that the fibre gets dry. Have a peep at the bulbs once a week, and if they need water, try to keep to the happy medium of not too much or too little. When the tops are an inch high, bring the bulbs into the light. Crocus and snowdrops are only successfully grown in a room without a fire or gas. Other bulbs—hyacinths, daffodils and tulips—do not mind warmth.

PLANTS IN RE

There is little doubt that our Photographic Competition, which closed in our issue of September 17th, greatly helped in establishing a personal bond among our readers, and in our desire to foster this spirit still further we are publishing in these pages photographs of various plants which are growing in several of our readers' gardens and which have been sent in as being of general interest. These illustrations are instructive as well as interesting, and may serve to give readers ideas for this coming season. We hope that, although our Photographic Competition

ANEMONE JAPONICA, A SHOWY AND HARDY AUTUMN FLOWERING PLANT.

THE accompanying illustrations show several plants that have flowered successfully this year in a number of our readers' gardens, and they have been selected as being worthy of the attention of others by reason of their merits. They are all plants that are easily obtainable, but not always met with in the majority of amateurs' gardens, and it is hoped by showing their decorative value in the garden, that others who have not as yet given them a trial, may be induced to grow them next year. This is the season when thought is being given to next year's display. How improvements can be carried out, and what new plants can be added to lend beauty and interest to certain parts of the garden. This past summer has been an unfortunate one for most gardens, except those in the north of Scotland, and no doubt many amateurs have been disheartened over the poor flowering display they have had and the number of failures of new plants they were trying out for the first time. But do not be discouraged by adverse conditions. There is always the consolation that next summer is certain to prove better than the past one, at least, it seems unlikely that it could prove more unkindly. That some plants have come through the ordeal of bad weather with flying colours is evidenced by these photographs, and on that account, they are worthy of consideration by all amateurs.

The picture of Anemone japonica, the Japanese windflower, shows what may be achieved by a gardener in the heart of London, and, in addition, illustrates the value of this anemone as a plant for the town or suburban garden. The clump has been grown on from one plant, which was broken up and replanted about four years ago. The plants are not fastidious in their requirements, no manure of any kind being given this year, and the result has been particularly gratifying. It is a most handsome plant with its decorative white blossoms and its elegant foliage. Every amateur should make a note of this windflower for including in his garden scheme if it is not already grown. It thrives in a partially shaded situation and is valuable on account of its late flowering qualities.

The red-hot pokers form another useful class of plants either for placing in clumps by themselves or for planting in the herbaceous border. They are at their best during August and September and even well into October, until the frosts and the winter rains put an end to their beauty. There are a number of excellent varieties of rich and vivid colouring which the amateur would do well to note at the present autumn shows. The one illustrated is Tritoma nobilis, which flowers earlier than the majority of the species. This plant has produced upwards of thirty spikes and has been a decorative feature of the garden for many weeks. The red-hot pokers take kindly to conditions in

ADERS' GARDENS

is ended for this season, and that less favourable photographic weather is at hand, readers will not be deterred from forwarding photographs of their gardens or of any constructional work that is being undertaken so that others may benefit from their publication. It is our desire to forge a personal link among our readers and to bring interesting personal experiences before the notice of all, so that every reader may benefit by the exchange of ideas. As has been stated previously, payment as for the competition will be made for all photographs published in this connection.

THE RED-HOT POKERS.

MARGUERITES BORDERING A GRAVEL PATH. SIMPLE BUT EFFECTIVE.

town gardens, and the only point the cultivator must guard against is the frosting of the young growths in spring. One way to prevent this is by tying and bending over the old leaves over the central portion of the crown.

Almost every amateur knows the ox-eye daisy or marguerite. It is a plant that needs no description or praise. Its worth as a border plant is well known, and in the accompanying illustration it is shown bordering the gravel path up to the house. Not only is it a useful and decorative plant in the garden for filling up odd corners and for clumps in the border, but the flowers have a certain value for house decoration. It is an old-fashioned plant whose merits and utility should not be lost sight of.

Though not usually regarded as hardy, the plant of Japanese pink, Dianthus Heddewigii, shown in the garden of one of our readers in the north of England, stood the winter perfectly. It is growing in a fairly dry situation and in one sheltered to some extent from the wind. Seeds were sown in early summer in boxes and the seedlings transplanted after the May-flowering tulips had been lifted. This early planting enabled the plants to become well established before winter set in. The plants were assisted by a spring mulching of well decayed manure, lightly forked in. Flowers are produced in profusion and it provides quite a bright splash of colour during the summer months. Other readers who have failed with this plant should give it another trial, following the method advised.

At bulb planting time one is always on the look-out for novel arrangements. Here is one sent in by a reader. A happy combination of hardy cyclamen and autumn crocuses or colchicums, planted round the base of an old tree. The effect is all that could be desired and is easily capable of imitation by those who have a similar position in their gardens which they wish to beautify. There are many more suggested planting schemes with bulbs which might be tried. One, in particular, which makes for spring beauty is by planting Glory of the Snow (chionodoxas) or the grape hyacinth (Muscari Heavenly Blue) round the base of spring flowering cherries or almonds. The two flower at the same time and the association is most charming.

It is often a problem to know what to plant in a narrow border beneath a window of the house. That the difficulty has been successfully met by one reader, who sends in this illustration of a border of mauve and white stocks, we think all will agree. It has provided beauty and fragrance to the border all through the summer, while in spring the border can be planted up with spring flowering bulbs, thus making it serve a dual purpose. Wallflowers and polyanthus primroses would also look very well in such a situation, and provide colour over a long period in the spring.

DIANTHUS HEDDEWIGII, WHICH IS MORE ENERALLY SUPPOSED.

A WELL ESTABLISHED DRIFT OF AUTUMN CROCUSES AND HARDY CYCLAMEN.

A useful form of garden decoration which should be carried out by many amateurs to brighten a dull corner.

NOTES ON THE FLOWER GARDEN

A Dual Purpose Plant.

Polygonum affine.

THIS is one of the most useful species of the Order and flowering in autumn, when the majority of alpines are past, it supplies a wonderful wealth of colour which is more than welcome at this season.

It is a native of the Himalayas and invaluable as a rock garden plant. By division it can easily be increased for covering ledges or mounds and being of a dwarf, compact and somewhat creeping habit, it soon forms a dense mass. The flowering period extends for some weeks in the autumn, during which a succession of beautiful spikes of white flowers are produced. As the flowers mature they assume a deep rose colour, which persists for some time, and this, contrasting with the young flowers, gives the plant a unique and very attractive appearance.

It has been grown successfully as a bedding plant and when planted *en masse* presents a pretty picture in September.

Although an old plant in cultivation, it is yet too uncommon in our gardens and ought to be better known if only because of the season at which it flowers.—A. MCCUTCHEON.

POLYGONUM AFFINE IS EFFECTIVE AS A BEDDING PLANT.

IT IS ALSO ONE OF THE MOST VALUABLE OF AUTUMN FLOWERS FOR THE ROCKERY.

How to Grow Tuberous Ranunculi.

THE soil best suited to these so-called bulbous plants is a rich, cool and yet well drained one. Many gardeners, to ensure best results, make up borders for them, using loam and a little, well broken up, old manure, particularly when the ground is a heavy and retentive clay. The tubers or bulbs are planted in this, with the claws downwards, 2ins. deep and 6ins. apart; some go the length of dropping sand and charcoal over the tubers before they are covered up. They may also be grown in pots for conservatory and greenhouse decoration. The time of planting is all-important, and it varies according to circumstances; in the colder north and where the soil tends to the heavy side, February is time enough, although they may be planted, too, as late as the end of March. In the south, no doubt, tubers will be planted out soon, but when early planting is adopted it is well to watch that the plants will be sheltered. The French ranunculi are probably best for outside decorative purposes, but it cannot be denied that the Turban and Persian kinds are more refined and dainty. The Giant Ragionieri kinds are more expensive but make a wonderful display, and some of those I had direct from Italy last year had flowers as large as 6ins. in diameter, almost like double begonias. —LANARKSHIRE.

A Good Evergreen Shrub.

Desfontainea spinosa.

THIS very beautiful evergreen shrub is peculiarly holly-like in appearance and, indeed, when not in flower may easily be mistaken for that ubiquitous subject. The shiny terminaal flowers are produced in summer; the corolla is scarlet with a yellow limb, tubular, and with the deep green foliage as an admirable foil, a very pleasing and striking effect is presented.

D. spinosa prefers a peat soil and thrives amazingly in company with rhododendrons and similar plants. It is perfectly hardy except in the very coldest parts of the country, and may well find a home in many gardens where choice and uncommon plants are cherished. The average height to which a specimen will attain is 3–4ft. Cuttings root with fair freedom and form a ready means of increase. I think, however, that a little heat greatly accelerates the propagation of this lovely shrub.

Distributed over the Andes from Chili to New Grenada, D. spinosa was introduced so long ago as 1853. It is an excellent plant for a cool greenhouse.—R. E. A.

Transplanting Christmas Roses.

THESE favourite flowers are most welcome about Christmas, but to have a supply of first quality blooms, the plants will need attention at other seasons. The finest blossoms are produced on two year or three year old plants, so when they have remained undisturbed for several years, it is advisable to lift them for division. When this is done the roots ought to be pulled apart with two forks, and not chopped with a spade. Each divided piece should consist of two or at the most three crowns, with as many roots as possible. The work of lifting and starting new plantations is often suggested immediately after flowering, but the best time for this operation is in early autumn. When planting, never replace big clumps intact or they will be a complete failure, if divided as stated above, they will be quite a success. Christmas roses are not particular in regard to soil, but it should be deep, so that the roots will always be cool, this being an important point. Where the soil is light, a little clay could be added with advantage. The positions appreciated by this group of hellebores are those sheltered from keen cutting winds and also protected from hot sunshine during the summer months. In many gardens the ideal spot will be available, almost any western exposure will be a success, especially where tall evergreens would supply the distant shade, which they so much enjoy. At the same time anything approaching dense shade must be avoided. Wherever they are planted the site should be well drained. Deep planting is not suggested, but they ought to be sufficiently low for the new roots which issue from the base of the crown to take possession of the soil. Directly the flower buds are seen, it is a wise plan to cover the clumps with a cold frame or hand lights which will protect the flowers from rain, and dirt.

Furthermore, the stems will elongate and render them more useful for cutting purposes. If no lights are available a mulching of straw will prevent rain splashes, and also slugs

Digitized by Google

must be caught, or these marauders will destroy many blooms.

About March a layer of partly decayed manure will be most beneficial; in addition to its food value, it will tend to keep the roots both cool and moist. Established plants will benefit by a weekly application of liquid manure during the growing period. Helleborus niger has white flowers when afforded protection as described above, and they may be had in quantity from the middle of December till February. There are several fine varieties, such as altifolius or major, also maximus, which produces large fine flowers and is one of the best; minor is smaller in all its parts, but has the merit of coming in flower earlier than the other forms quoted.—T. W. B.

Biennials: Planting Out.

WE have now reached the time of the year when it is needful for those who sowed seed of biennials last spring and afterwards transplanted them in nursery beds, to give them a shift into their final quarters. Upon this last removal, and the manner in which it is done, depends not a little of their success. Subjects like wallflowers, Canterbury bells, foxgloves, and honesty, deserve something more than being taken from the ground minus soil at their roots, as one notices repeatedly in the case of wallflowers in late autumn. It is not a matter for surprise that these beautiful spring-flowering plants show their resentment and dwindle off, especially during early frosts.

Having had their care all through the summer months, it is important that this last removal should be properly done with a minimum of root disturbance, and though it may be a lot of trouble to deal with each plant individually in transferring them to new quarters for blooming in spring, it is, I feel sure, the safest way to guard against failure and pave the way for strong established plants, and eventually the best show of flowers.

I would urge those who have biennials in hand to disabuse their minds of the idea that if the work is done next spring it will suffice. In nursery beds, owing to the wet summer, some of the plants mentioned have grown out of all bounds, and to leave them there would be a mistake. He is wisest who sets about the job and gets it completed by the first week in October, if at all possible, and that without disturbing the roots more than need be. Firm planting is essential.—CLAREMONT.

Transplanting Seedlings.

(*Perennials*).

IN these days seedlings of perennials are very precious and are, as a general rule, well treated by experts. These border plants occupy much space in our gardens and provide some of the most gorgeous displays of colour in our exhibitions. At home we find the various kinds of plants flowering over a long period.

Seedlings are greatly strengthened by judicious transplanting. If the majority are allowed to grow without being transplanted, they become lanky and do not possess fibrous roots in abundance before the flowering stage. Soils vary so much in different parts of the country, even in the same district, and transplanting should be done before the winter comes or deferred until spring, according to the condition of the soil in each case. Where everything is convenient for this work being done in the autumn, I strongly advocate it, as the young plants get established before the severe weather comes, then they grow and flower profusely the following summer. In the case of delphiniums, where clayey soils exist, I advise the retention of the young plants in their nursery beds, if transplanting cannot be done very early in the autumn, until the following spring, even where the border soil is light. Ninety per cent. of other kinds of plants can be safely shifted both late in autumn and early in the spring where the soil is light and open. Select the naturally moist borders for polyanthuses and primroses; fairly dry ones for pyrethrums and antirrhinums; two positions—if they are available—one moist and one rather dry for Michaelmas daisies to obtain a longer period for flowers. All the heleniums and helianthuses take up much moisture during the summertime while they are growing freely and, consequently, the best is not obtained from them when the plants are grown in a shallow, dry soil. The herbaceous phlox is a subject that does well in partial shade, not too near to the roots of trees, but in the shade of the branches, and then the best is forthcoming—good foliage and large blooms free from sun-scorch. Unflowered seedlings can be dealt with at an earlier date than those raised last autumn and retained in nursey beds until this. I have a nice batch of seedling Michaelmas daisies resultant from seeds sown in a box last spring. The plants are now developing their flowers, and it is very interesting watching the flowers open, as they are so varied and come from the finest collection in the country. Directly the full beauty of the blooms can be seen the flower-stems will be cut down and the young plants transferred to larger borders. The same treatment will be meted out to gaillardias, erigerons, Scabiosa caucasica, Coreopsis grandiflora and other favourites. Biennials are generally well treated; do not neglect seedling perennials, it pays to treat them well.—G. G.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

IT is useless to retain tomato plants in a cold greenhouse, as it is only on rare occasions that sufficient natural heat is experienced at this advanced season of the year to assist the ripening process of the fruits that remain. Besides, the ground is required for wintering border plants that require protection. The green tomatoes may be used in the preparation of chutney, while those specimens that are partially coloured should be placed at a window in a fire-heated apartment or on a shelf near the roof of the greenhouse. As a preventive measure in the spread of disease, burn the plants and sterilise the soil before being occupied by other subjects. When tomatoes are cultivated, as they frequently are, in pots and boxes it is a great temptation to use the soil for other garden purposes; but, rather than run the risk of disseminating disease by means of the spores in the soil, it would be better to consign it to the rubbish heap or bury it deeply in a part of the garden where root crops are not grown.

The autumn leaves are falling fast, and if the paths and beds are to be kept in a tidy condition during the next few weeks, time must be devoted to their collection. Leaves are particularly objectionable in wet weather, and when lying in layers they keep the surface of the ground in a state of excessive moisture and become a favourite protective resort for slugs and other insect pests. When the leaves are in that condition it is advisable to bury them; when they are dry, burn them and store the ashes in a dry place for future use, because mixed leaves, and particularly the leaves of shrubs and those of the plane tree, are not good for making into leaf-mould. The leaves of the oak and the beech are best adapted for that purpose, and as these trees are seldom to be found in small gardens the alternative methods of disposal are recommended. Leaves take a long time to decompose, and when buried in quantity in wet, heavy ground they are apt to produce vegetable acids that are detrimental to plant life. Decay may be accelerated by mixing the leaves with the soil, and the process will be further quickened by the addition of a liberal sprinkling of lime. When gathering up leaves on a walk, the work is quickly accomplished by using a wooden rake, but on grass an ordinary broom is the most effective implement. Never gather dry leaves into a heap and allow them to remain in that state, as they are easily scattered again by a slight breeze or other agencies. Burn them at once is the safe motto.

The new season's rose catalogues having been distributed, amateurs should act about the task of selecting the varieties that are required to make good losses, which have been exceptionally numerous this year, or for furnishing new beds in contemplation. It may not occur to a number of readers, but there are distinct advantages in placing orders early in the season. It is the rule in most nurseries to supply orders in the rotation in which they are received, and by that arrangement the early customer usually gets the pick of the stock, whereas the late-comer runs the chance of being supplied from the residue or, in the case of popular varieties that are frequently sold out, he has to be content with "bought in" bushes. It must also be kept in mind that, although orders are placed thus early, a month or more may elapse before the roses are in a condition to be lifted. In a mild autumn the trees may continue to bloom until the eve of winter, and it is only when the sap has almost ceased to flow and the leaves are in process of decay that they are in a suitable state for transplanting. Given a normal season, the work generally begins about the end of October or the beginning of November. But, apart from these considerations, it is advisable that autumn-planted roses should be transferred to their new quarters while there is still a little warmth in the soil, for they will root much quicker and become established before winter sets in. Hybrid tea roses are more hardy than some folks imagine, and even in our severe Scottish climate they survive both frost and storm without protection in the form of a surface covering of stable or farmyard manure. In the event of forming a new rose bed, no time should be lost in preparing the site by digging the soil two spades deep and enriching it with a liberal supply of old manure from farmyard or stable.

Although there is no necessity for putting in tulips before the end of the month, and good reasons might be advanced in favour of further delaying the work until the middle of November, the advent of October generally inaugurates the bulb-planting season out of doors. By that time the ground occupied by summer bedding plants will be vacant, and, provided it has been dug over and cleaned, the planting of hyacinths and daffodils can be undertaken when soil and weather conditions are suitable. The arrangement may either be a matter of taste or expediency, but only in exceptional circumstances should daffodils be planted singly in a straight line. Whether the available number is large or small, aim at setting them out in clumps. In a small piece of ground of narrow dimensions small clumps of three bulbs might be adopted as a minimum, but in a mixed flower border, and when established in grass,

Digitized by Google

daffodils are seen to best advantage when grown in groups of half a dozen and upwards. Golden Spire, Emperor and other large trumpet varieties associate well with dark shades of wallflowers, and the pleasing effect may be emphasised by an edging of forget-me-nots. Of the other bulbs that bloom in the spring the beauty of the pretty little Muscari Heavenly Blue should not be overlooked. These grape hyacinths are as easy to grow as snowdrops, and when undisturbed they multiply and spread quickly. The clear blue flowers, which appear in March and April are clustered like miniature grapes at the top of the spike and, being cheap to buy, they deserve to be more frequently seen as an edging to the mixed flower border in spring. They are also suitable for the rockery or for growing in pots. Plant the bulbs in October about 2ins. deep and the same distance apart.

If not already done, wallflowers and Canterbury bells should have a final shift, as there is usually plenty of vacant ground available. As these biennials have to contend against winter storms, firm planting must be the rule. Tread the ground until it is fairly solid, and dibble in the seedlings in lines, allowing a space of 9ins. to 12ins. between each. It is a common mistake on the part of gardeners who do not take the trouble to raise their plants from seed, to purchase wallflowers in spring when the flower beds are formed. Autumn planting gives the best results, and to provide against the losses that occasionally take place a few of the surplus plants should be kept in reserve.

Main crop carrots and beet are now ready for lifting. A sunny day should be chosen for the purpose, as the roots require to lie on the surface for a few hours in order that they may be in a dry condition for storing in a frost-proof place. In digging beet care must be taken that the roots are not damaged in any way, otherwise they will bleed and lose colour, a condition that renders them unfit for table use. Unlike carrots, the tops of beet should be twisted off and not cut; but both vegetables are best preserved in boxes of dry sand if the crops are not large. When grown in quantity the roots may be placed in pits or clamps in the same way as potatoes.

Bedding calceolarias and pentstemons are herbaceous perennials, but it is customary to treat them as biennials by raising new plants each year from seed or cuttings. For the latter system of propagation a cold frame from which frost can be excluded is all that is required. Early in October select well-seasoned side shoots of pentstemon and, after detaching them carefully from the parent plant, remove the two lowest pair of leaves and make a horizontal cut just beneath the lowest joint. The rooting medium should consist of a light sandy loam, and the cuttings may either be inserted singly in small pots or half a dozen may be placed round the rim of a 5in. or 6in. pot. When this is done, water thoroughly, and place the pots in the frame, which should be kept closed and shaded from bright sunshine until the cuttings are struck. When growth begins air may be freely admitted, and in the event of a sharp spell of frost setting in protection in the form of a mat put over the frame at night is a necessity. Although calceolarias are almost hardy, the treatment of cuttings is practically the same as that given to pentstemons. Potting, however, can be dispensed with by inserting the shoots in sandy soil in a frame after the manner of treating pansy and viola cuttings. Being evergreen, the cuttings retain their leaves all the winter through, when damp causes more trouble than frost.

This is the time of the year when it repays a gardener to devote a little time and attention to his garden tools. Before they are put away for the winter the various implements should be thoroughly cleaned and the metal parts saturated with oil. This advice applies particularly to the mower, the neglect of which is frequently the cause of unsatisfactory working in summer. Dirt adhering to the blades should be removed with a hard brush preparatory to coating the steel with vaseline.

ST. MUNGO.

FRUIT AND KITCHEN GARDEN

This Month in the Fruit Garden.

IT is during October that the planting or transplanting of fruit trees may be commenced. A dry day should be chosen and the roots of the trees trimmed with a sharp knife before planting, taking care to spread the roots, on planting and not to plant too deeply. Soil should be worked in between the roots and after planting the ground should be made firm. Apples, pears, plums and small fruits may be planted.

Cuttings of currants and gooseberries may be taken this month. Remember to remove the lower buds from red and white currants and gooseberries, but to leave them on black currants.

Gooseberry and currant bushes may be pruned as soon as the leaves have fallen. Just thin out the weak shoots of the black currant and spur prune the red currant and the gooseberry.

Fruit trees may be given a spraying with lime-sulphur at winter strength, *i.e.*, one gallon of lime-sulphur, specific gravity 1.3, to 29 gallons of water. This will act as a cleanser and kill the young caterpillars of such pests as the brown tail moth, ermine moth and the codlin moth. To trap the moth called the mottled umber, grease bands should be applied by the middle of the month.

Such pests as the maggots of the gooseberry sawfly, pear slugworm, social pear fly, that hibernate in the soil during the winter and also the grubs of the raspberry weevil and cockchafer, can be got rid of by the application of a soil fumigant such as Napthalene, applied, after removing the top 6ins. of the soil, at the rate of one half a pound per 6ft. spread of tree and forking in is recommended. The soil removed should be burnt.—H. D. B.

October Work in the Vegetable Garden.

OCTOBER is the chief vegetable lifting month, especially in northern districts. The main-crop potatoes go into the clamp, which is well earthed over before hard frost sets in. Carrots and other roots go into the store heap as soon as they are ready to lift. Protection must be provided for such crops as require it. Cauliflowers that are ready may be lifted with earth at their roots, and placed in cold frame, shed or elsewhere out of the reach of frost. Lift lettuce and endive and treat similarly. Take care in lifting beet not to break any of the roots. These are best stored in moist sand or peat moss litter. Carrots keep very well on the floor of a shed with some sand or wet peat dust thrown over them. Parsnips must be kept in moist sand or earth; but these roots may, with advantage, be left in the growing plot, and be dug up as required.

A few of the August-sown cabbages may now be planted out in lines a few inches apart, so as to relieve the congestion in the seedling bed. Leeks may be fed with liquid manure during mild weather. Give celery its final earthing up before frost or the autumn rains set in. Heavy rain washes down the ridges, and it is often necessary to replace the soil after the rain.

Clear away and burn all such rubbish as potato haulm, and make preparations for the manuring, digging or trenching of all vacant ground.

Mulch, with littery manure, asparagus, rhubarb and seakale by the end of the month. —J. W.

Growing Tomatoes for Winter Use.

CULTIVATORS who possess warm greenhouses or other glass structures, where artificial heat can be maintained at about 58 degrees as a minimum night temperature, may succeed well in growing tomatoes throughout the winter months. Cuttings rooted in October or seeds sown forthwith, would answer the purpose. The best results are generally obtained from plants confined to pots and not grown in a border, though it is not absolutely necessary to confine them to pots. If cuttings are to be rooted, select some of the tops of plants now fruiting and unstopped. Also, insert several side shoots to bear fruits later on. Cuttings usually grow more stocky — sturdy — than seedlings. It is essential that the soil used be porous in nature and well firmed in pot or bed. In the case of seedling tomatoes two transplantings should be sufficient—one while they are quite small into 5in. pots, singly, and the other into 9in. pots, in which they should be fruited. The lightest position under glass should be selected for the plants from the seedling to the final stage and, if the plants can be kept from 3ft. to 6ft. from the roof glass there will not be any danger of weakening through being drawn up unduly. The compost should consist of fibrous loam two parts, rotted manure one part and leaf-soil and wood ashes one part. Leave room for several top-dressings and then very little extra feeding will be needed. As long as possible, while the weather conditions permit, ventilate rather freely, as in the depth of the winter very little ventilation is possible. Keep the atmospheric moisture down to the minimum.—HANTS.

How to Grow Mushrooms in a Greenhouse.

FINE crops of mushrooms may be grown in a greenhouse or similar structure without any harm being done to pot or box plants. Many amateur cultivators try to grow mushrooms every year in sheds and fail oftener than they succeed. If they pay close attention to the following hints they will not fail provided new spawn is used. The horse manure should be collected every day and spread out thinly in an open shed, being turned over daily, to allow the rank gases to escape. When sufficient has been collected in this way to make up into a solid bed about 6ft. long, 3ft. wide and 16ins. deep, form a conical-shaped heap in the shed, leave the manure so for a day and a night, then spread it all out thinly and you will see hot steam rising from it. In this way the manure is sweetened, that is, the rank gases are expelled and, when made up to form a very firm bed the heat engendered will be steady and lasting. I have made my mushroom bed under the plant stage placing boards between the bed and the hot-water pipes, with mats 1ft. above the bed and draped from the front of the stage. Thus, practically all steam was confined and used up for the benefit of the bed, as a regular atmospheric moisture is beneficial to the mushrooms. Place a layer of new loam 2ins. deep on the bed directly the lumps of spawn have been inserted just under the surface of the manure at 9ins. apart. Firm the soil with the back of a clean spade and cover the bed with clean straw to a depth of 6ins. Do not water the bed; directly young mushrooms appear—as they should do in about six weeks time—remove the straw and replace it with sheets of brown paper. The mushrooms will grow white and clean under the paper.—CHRISTCHURCH.

PLANTING A HEDGE

How to Succeed and the Plants to Use.

ONE of the first things to consider when planning a new garden is the planting of hedges. Sometimes, even before the house is built, when the plot of ground is purchased, the boundary lines are marked out with a few posts and wire, and a hedge planted, so that when the house is built ready for occupation there is already a hedge forming at least a fairly good permanent boundary to the garden.

In addition to their use as boundary or dividing lines from neighbouring gardens and the road, tall hedges are often planted to form screens to shut out undesirable buildings, or to give shelter and privacy to one's lawn and garden. If the garden is

THE PLANTS IN POSITION FOR PLANTING.

situated on high ground and much exposed to cold winds on one or two sides, then it is desirable to plant shrubs which will form in time a tall hedge, to shelter the house and at the same time give protection to the flower-beds and borders, for, as most readers are aware, it is a heartbreaking business trying to garden on cold, wind-swept ground.

Though the planting of a screen or hedge to prevent a garden being overlooked is not so difficult as that of providing a wind screen, it requires some thought and care in the choice of subjects and planting, so that the whole may become, when finished, not merely a screen, but an attractive and pleasing link in the whole scheme, a background, perhaps, for flowering trees such as almonds or Japanese cherries, or for the herbaceous border

The subject of hedges, or dividing lines, between different parts of the garden may be under consideration at the present time in connection with alterations proposed in the garden this coming autumn and winter. A hedge between the vegetable garden and flower garden, such as a hedge of lavender or rosemary, sweet briar, or a free-growing rose like Gruss an Teplitz or Zephyrine Drouhin, round a formal paved garden, or surrounding a rose garden, add to the interest and attractive character of a garden.

It is very necessary to dig deeply and manure the ground 1½ft. to 2ft. deep previous to planting a hedge. When preparing for planting, place a line along one side and dig out a trench 6ins. to 9ins. deep and 1ft. or more in width, according to the amount of roots the plants possess. The

Distance Apart to Plant

depends largely on the kind of shrub employed. They should be planted close enough to ensure the plants filling and thickening up at the base quickly. For such subjects as Lonicera nitida, shown in the illustration, privet and quick (thorn or May), 1ft. apart, is a suitable distance. As a rule, the taller the hedge required the wider apart should the bushes or trees be planted, as, obviously, an increase in height also means at least a slight increase in width. The fact of keeping bushes for hedges dwarf and compact by pruning with several leads usually induces plenty of fibrous roots, which are a great aid to quick and successful growth, when planted in the permanent positions.

Partially fill in the trench with soil as planting proceeds, treading the soil firmly with the heel before completely filling the trench. Tread again, and then leave a flat channel with a ridge of earth on either side, so that when watered the water will soak in round the plants.

One very valuable use of hedges in a garden is that, in addition to seclusion, the garden cannot be seen all at once. In wandering round and coming unexpectedly on first one feature and then another, it makes the garden appear more extensive than it really is.

The number of close-growing trees and shrubs suitable to plant as hedges and screens is much larger than is generally known: at least, it leads one to think so from the frequent use of privet, yew and one or two other shrubs. In many positions flowering shrubs could very well be planted instead of the closely clipped, uninteresting privet, yew and holly. Quite a number of shrubs, other than those commonly planted, including a number of flowering shrubs, can be pruned to form most attractive hedges. In pruning flowering shrubs the best time to prune should be guided by the flowering season in the case of early-flowering shrubs like the Berberises Darwinii and stenophylla. Late-flowering shrubs, represented by the New Zealand daisy bush, Olearia Haastii and Veronica Haastii, are best hard pruned in April, sacrificing, if need be, one season's flowering when the bushes are growing beyond the limits of a useful hedge.

Everyone will be familiar with the fine old yew and holly hedges in old gardens which have taken many decades to attain their present size and value. The present day need

TREADING IN THE PLANTS FIRMLY.

is usually for something quicker in growth and cheaper to purchase.

The evergreen bush honeysuckle, Lonicera nitida, from China, makes a very neat, fast-growing hedge, and stands clipping with shears almost, if not quite, as well as privet. In addition to several evergreen flowering shrubs already referred to as suitable in these notes, the following are deserving of attention: The laurustinus (Viburnum Tinus) readily grows to a height of 5ft. to 6ft. or more, and does well in partial shade. The double-flowered gorse makes an impenetrable hedge for a garden bordering a field in which cattle graze. In the warmer parts of the country, Escallonia macrantha is effective.

THE COMPLETED HEDGE.

Hedges of roses are deserving of more attention by planters. The Scotch rose (R. spinosissima), the Japanese rose (R. rugosa), the sweet briar (R. rubiginosa) and the common dog rose (R. canina of the hedgerow) are all useful and attractive. As a dwarf, closely-clipped hedge the box (buxus) is very largely planted; the lavender cotton (Santolina chamæcyparissus) is also effective as a dwarf hedge.

As general utility hedges from 6ft. to 10ft. or more in height, the beech, hornbeam and Myrobalan plum are free-growing, and, with annual clipping, can be kept well furnished to the ground. For a cheap impenetrable hedge to plant extensively where cattle graze, the quick or hawthorn is unrivalled. A list of the best trees and shrubs to form quickly

Tall Evergreen Hedges

or screens includes the evergreen oak (Quercus Ilex), Thuyas plicata (Lobbii) and occidentalis, Cupressus Lawsoniana and, fastest in growth of all, C. macrocarpa, but the latter is rather tender and only really suitable for gardens in the south and west. Only this week I saw a hedge of the latter. Two years ago the plants were put out from 5in. pots; now they are from 6ft. to 8ft. high. The Lombardy poplar is a most useful tree for tall hedges and unrivalled to form a screen quickly. Trees 8ft. to 12ft. or even more in height can be readily transplanted, and, though not evergreen, the branches are so numerous and closely set as to form a very good screen in winter. A. O.

USEFUL AND SHOWY SHRUBS FOR GREENHOUSE DECORATION

BULBS play an important part in keeping up the flower supply in the greenhouse after Christmas; while stocks, schizanthus, primulas and cinerarias also contribute largely to the gaiety of this structure in early spring. These are well-nigh indispensable, especially for low houses; but there are many greenhouses and conservatories with a centre stage which require rather taller subjects to make them useful and attractive before the flowers outside appear in quantity. Fortunately, we have plenty of material to choose from in the shrub line, and, moreover, inexpensive if they are home-grown on a spare piece of ground, lifted, and potted as required. Many of them can be kept in their pots for several years if placed outside during the summer and autumn, fed occasionally with liquid manure, and kept well supplied with water. One of the first to notice are the deutzias, all of which are white; but, nevertheless, they show a good deal of variation. D. gracilis is a popular species, and a number of Lemoine's hybrids, especially D. Lemoinei, is a beautiful shrub when flowered under glass. After flowering, a little pruning is needed, which consists of cutting out the old wood. It is advisable to encourage new growth before the plants are hardened off in readiness for their summer quarters.

The numerous varieties of Azalea indica and A. mollis are very showy, and the same remarks apply to rhododendrons, which can be obtained in various sizes. Well budded examples should be chosen, and the rooting medium is largely made up of peat. It is not so easy to keep up a stock of these plants for pot work, but with care the varieties of A. indica can be kept in good health for a number of years, especially if they are not neglected during the summer months when making their buds. The rhododendrons can be planted out in the borders, when finished, or too large for the greenhouse. One of the best plants for our purpose is Forsythia intermedia spectabilis, the finest of the family, and can be relied upon to furnish an early display. It strikes readily from cuttings, and when rooted they should be planted out in the open, where they will, in two or three years, make excellent specimens for pots and the greenhouse. Among the prunus will be found the large semi-double pink P. triloba and the flowering almonds and peaches. In the Japanese cherries we have a glorious selection, and the large double rosy pink form known as J. H. Veitch is one of the best, closely followed by Watereri, a slightly deeper rose than the former.

The sweet-scented Viburnum Carlesii is now well known, but, protected from heavy rain and wind, it is indeed a glorious plant. V. fragrans is also a fine companion to the preceding. The lilacs constitute a charming group and may be had in great variety, and, after being employed for a few years in the cool greenhouse they would enrich the shrub collection outside. Among the double-flowered will be found the pure white Miss E. Willmott; C. Joly, very dark red; M. Buchner, pale lilac; and many others; and in the single-flowered group we have Hugo Koster, reddish mauve; Marie Legraye, cream white; S. de L. Spath, dark red purple; and Charles X, rosy purple; while a fine white is alba grandiflora. The common laburnum is very useful and always produces a good show, although the chains of yellow blossoms are not always so long as those outside.

Staphylea colchica or bladder nut is largely employed for the greenhouse where its white flowers in terminal clusters are always admired. A popular subject is Hydrangea paniculata, but to obtain large heads the plants should be pruned hard after flowering, and then induced to make strong growth by liberal feeding of the roots. Jasminum primulinum, if well grown, will be a most beautiful shrub for the greenhouse, and it often blossoms more freely if grown in pots than outside. The dwarfed forms of Wistaria sinensis, with their large clusters of mauve-blue flowers are always appreciated, and they readily respond to greenhouse treatment when well rooted.

There are other shrubs suitable for early work in the greenhouse, but enough have been mentioned to show what a large number of plants can be had in bloom a few weeks earlier than those outside, with very little trouble. Those plants intended for the greenhouse should be lifted during the autumn and placed in pots which will just take the roots after these have been reduced to reasonable proportions. Plunge the pots in ashes, and take the plants into the greenhouse at the beginning of the New Year. Fibrous loam and a little leaf-mould will be found an excellent rooting medium. T. W. B.

THE CULTURE OF RASPBERRIES

There is no more profitable fruit than raspberries, but to obtain the best results they need to be treated generously. The difference between a bountiful crop and an indifferent one may be summed up in the word "culture," not only preceding the fruiting season, but in the attention the canes receive immediately fruit has been gathered.

TO grow raspberries well, preparation o the ground should be the first consideration. It is scarcely possible to make it too rich, or deep, or moist. Stiff clay alone is not helpful, and where this exists it must be broken up, and rotted manure, leaves or road scrapings incorporated, in order to provide humus for the roots to ramify. If this is arranged for, say, 3ft. deep, the best of the manure being kept within a foot or so of the surface (for raspberries are surface feeders), then one will lay the foundation, so to speak, of success for heavy baskets of fruit. The work of preparing ground should be undertaken in early autumn.

Situation for Planting Canes.

If it is possible to make a selection where planting should be made, then a sunny site should be chosen; but, as already intimated, it is not a fruit which depends on the sun to bring it to maturity, as—other things being satisfactory—good crops can be secured from canes growing in partially shaded positions, as on the north side of a garden. It is useless to expect good results in dry, shallow soils, having regard to the fact that the roots of raspberries do not lie very deep.

Planting.

While planting may be done up to March, it may be pointed out that October and November are the best months for removal and planting of canes, as then they are more likely to become established. Six feet ought to be allowed between the rows and 4ft. between the stools. Any less distance allowed than this is likely to lead to overcrowding and confusion before long; indeed, there is nothing lost in giving raspberries ample space for growth, and to enable one to get among them with a degree of comfort. More especially is this so with vigorous growing sorts.

Training.

Raspberries are very accommodating in the matter of training, and various methods are open to the grower. For example, in the case of some varieties, they may be trained over wire arches, pergola fashion, or planted in clumps about a garden suitably staked with stout poles; but in a general way it will be found the better plan is to stretch strong wire, fastened to strong supports at either end of a row, with stakes provided at intervals as may be necessary; or it is open to the cultivator to make a framework of laths or oak rods, which give much more support to canes, and to these the growths can be tied out from time to time. There is nothing, in my judgment—after many years of experience—to beat a framework, commencing with the first laths about a foot from the ground, and so prevent canes being blown about by rough winds, which is rather important from the sucker stage before they reach the nut brown state and begin to stiffen and are less liable to snapping off.

Pruning.

As applied to raspberries, pruning differs from the method of other fruit trees, inasmuch as it consists of taking away all the old wood, as well as part of the new, every year; and, for the information of beginners—for which this article is mainly written—it may be observed that it is a rule which admits of few exceptions if one desires fruit of quality and to keep up a healthy stock. This pruning, to be effective, must be done in autumn, and the reason is this: When a cane has once borne fruit, it has fulfilled its mission and, so far as future use is concerned, may be ruled out of account entirely. It will be obvious, therefore, to the merest tyro that there is nothing gained by retaining useless shoots which only hamper the growth of young suckers fighting for existence among a forest of dying leaves and worn-out branches. On the contrary, there is everything to be gained by clearing this old material away at the first opportunity, and giving the new growths all the light and air possible. Until this radical removal of old shoots and branches has been made, the suckers (next year's fruiting canes in the making) cannot have the chance which is necessary for them. Having disposed of the fruiting canes of this year, attention should be turned to the many suckers which have pushed up from the stools. It will be found that they are most prolific, and because of this they must be reduced in number. A leaf from my own book will illustrate what is meant. At the end of July, when gathering fruit, I was struck with the almost abnormal growth made by suckers this year, and was curious enough to measure some of the strongest which had grown out of the sides of the rows as if searching for light, and found them to be well over 7ft. high; and at some stools there were as many as twelve suckers. These will be reduced to four or five at the outside, as from this number the finest fruit is borne. It will be thus seen, in so far as old-established stools are concerned, that by late autumn there is nothing visible but new growths which will not need to be shortened until the following February or March—3ins. or 4ins. It is not unusual for some of the most advanced suckers to produce some fruit in the autumn, particularly in mild localities.

Newly Planted Canes.

Where new canes are to be planted—say in November—and the ground has been prepared and supports put up, plant the roots up to the level of the crown, spreading them out, tying the canes to the supports so that wind will not unsettle them. After

Digitized by Google

finishing, tread the soil well about the roots. The plan which some follow, of shortening canes at the time of setting them, is not to be commended, the reason being that during winter they are likely to become damaged either by frost, or soaked with water owing to the pithy state of the canes. It is enough if pruning is done towards March, taking away all the growth from 18ins. off the ground.

Winter Dressing.

The present season has been one of the best for raspberries in most places, owing to so much rain; and where the canes received attention last winter in the matter of dressings, crops have been heavy. It has been so in my own case, and not a little of this is due to the treatment the established stools had last year. At the time of clearing away the old canes, the rows were forked over, and received a dressing of bone-meal, and this was followed a few weeks later with rough leaves and road scrapings spread over to the depth of several inches, no manure being then available. Again in April, when, for a few weeks, the weather was dry, the rows were supplied with water and, after the fruit set, they had several soakings of liquid manure. This entailed labour, but it has been well justified, as I have never had better crops.

Varieties.

It is a point in favour of some of the oldest sorts that they still are noted croppers and are yet largely grown. Such are:

Baumforth's Seedling, bearing fine fruit of deep crimson.
Pyne's Royal, one of the largest.
Devon, a heavy cropper.
October Red, a reliable late in certain districts.
Superlative, perhaps the most popular of all, being reliable and a heavy cropper.
Yellow Four Seasons, a late bearer.
The Guinea, a yellow Superlative.
Lloyd George, a fine red-berried modern sort, coming both early and late, and is also a heavy cropper.

Where there is only room for one sort, I question whether, as an all round variety, there is anything to beat Superlative. Carter's Prolific, another red sort, lives up to its reputation as a heavy cropper, with large fruits borne on stout canes.

In planting October Red and Yellow Four Seasons, preference should be given to a sunny position, so that in the late autumn advantage may be taken of every gleam of sunlight.

General Remarks.

For suburban and small gardens, it would hardly be possible to point to a fruit more reliable or so serviceable as the raspberry, either for jam or for dessert, as, be the season what it may, it seldom disappoints so long as it is given right treatment at the proper time. W. F.

WHAT OUR READERS SAY

THE MYSTERY OF THE MUSK.

SIR,—One of the perplexities of the plant world to-day is what has become of the fragrance of the musk. Only a few years ago this little plant, famous for its delicious perfume, was to be seen in cottage windows throughout the length and breadth of the land. At the present time few people trouble to grow musk because its fragrance—which was three-quarters of its charm—has completely disappeared. A wide search carried out last year by a well known horticulturist did not discover a single specimen of the musk that still possessed the odour which one has always associated with the plant. Advertisements inserted in garden journals failed to bring any news of musk which had retained its fragrance. There seems to be no reason or explanation for such a remarkable change on the part of this plant, which now seems likely to go out of cultivation altogether. Curiously the last fragrant musk plants seem to have existed on the East Coast of England. The plant always grew particularly well in the bracing breezes that come from the North Sea. For long it was claimed that the most highly fragrant musk in the land was that to be found in the seaside resorts of the Norfolk and Suffolk coast. A single specimen would be worth a considerable sum to a dealer in plants. Even a few cuttings, or one or two seed capsules, would be of value, for the musk is easily propagated and it is likely that the new subjects raised would be the old-fashioned fragrant type. — S. LEONARD BASTIN, *Bournemouth.*

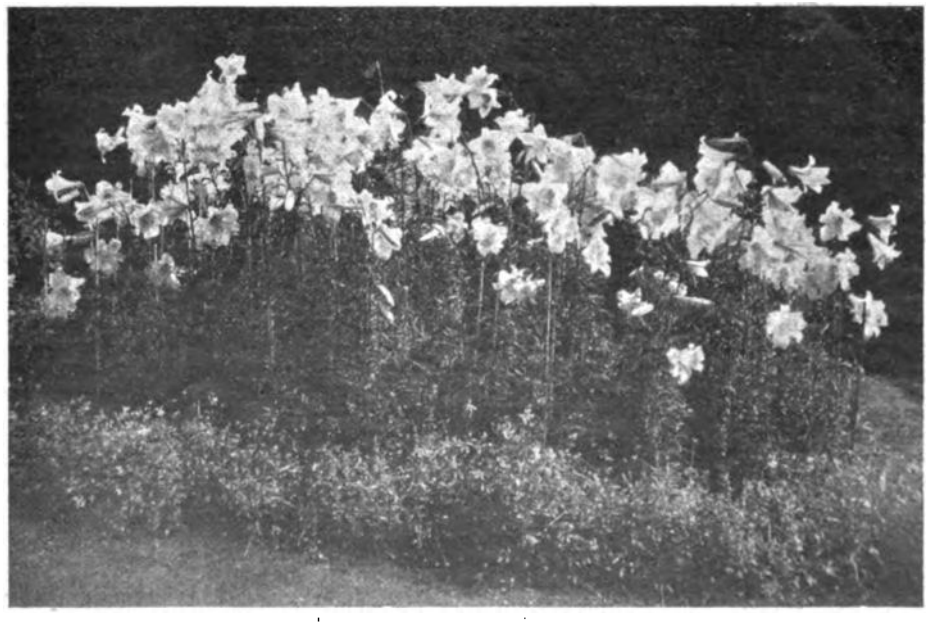
LILIUM REGALE.

SIR,—This splendid lily, a recent introduction from western China, has proved the easiest of all to grow from seed.

Six bulbs were purchased in 1924—they flowered in July of that year. The seed ripened well and was sown in boxes the same autumn. It germinated quickly, and the resulting plants were wintered in a cold frame. In 1925 they were planted out in the latter, and in spring of 1926 they were transferred to the open ground which had been well prepared with leaf-soil and sand. Several flowers appeared in July—less than two years from sowing—and this photograph was taken on July 10th, 1927.

The whole batch have flowered, as shown, in less than three years from the time the seed was sown. The stems are from 2½–4ft. high, bearing from two to six or more large trumpet-shaped white flowers flushed with primrose internally and shaded externally with deep pink, which, shining through the petals, gives them a soft pearly pink glow.

This lily is a glorious acquisition to our gardens, and any amateur who has a cold frame or, better still, a greenhouse can raise this grand plant as easily as an ordinary annual or perennial flower; but, of course, patience is required for them to attain flowering size.—H. VICTOR VOLES.



A FINE BED OF LILIUM REGALE GROWN FROM SEED.

OMPHALODES LUCILIÆ.

SIR,—Much has been written about Omphalodes Luciliæ, and various methods of treatment have been advocated and practised, but the plant remains a stumbling block to many gardeners who have loved, and too frequently lost this exquisite plant. I am not putting forward any method as being certain to command success with this notoriously difficult but fascinating subject; much depends upon the climate of the district in which the garden is situated. There is one thing, however, which sometimes proves a nuisance, and this is the havoc the slug will bring if it succeeds in reaching the omphalodes. All expedients tried have proved useless unless the slug was searched for and as carefully guarded against as possible. In this all teachers agree, but when we come to position, we have a greater diversity. The fullest sun is advocated, but one knows places where slight shade seems essential if this omphalodes is to live and succeed. A light, rich loam, with plenty of chips and broken mortar is also favoured, but I have seen it flourishing in a low moraine bed with about 3ins. of gravel above a few inches of loam, with ample drainage composed of stones below, and slightly shaded by neighbouring shrubs. No lime was supplied, yet no one could hope for healthier plants. This question of sun or shade is an important one, which, as already remarked, will probably depend upon the district in which O. Luciliæ is grown. In one with cloudy skies and heavy annual rainfall the sun will probably prove better, but in one with clear skies and a less abundant rainfall the shade will be likely to be beneficial. No doubt it is a crevice and sun-lover at home, but we have frequently to accommodate ourselves to changed conditions. Almost anything is worth trying to secure the health and happiness of this gem, with its wonderfully beautiful glaucous leaves and its still more exquisite porcelain-blue flowers. A little exchange of experience may help to elucidate the best way of cultivating the beautiful O. Luciliæ in various parts of the British Isles.—S. ARNOTT, *Dumfries.*

OUR SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with each enquiry.*

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Scab on Potatoes and Apple Blight.

Will you please tell me the remedy for the scab on the enclosed potatoes, and whether anything can be done for it at the present time or only when the ground is prepared? All potatoes on the same root are not affected. What is the remedy for the blight on the enclosed apple leaves, which was very prevalent about a month ago but is not so evident now? Is it the same as C. S., Marple, in your issue of August 13th? What can be done for large numbers of fungi (toadstools) in a lawn?—H. J. P., Birmingham.

Your potatoes are suffering from the common scab on potatoes, Actinomyces scabies. We advise you to avoid alkalinity in soil. Do not dress the ground with lime, but substitute with superphosphate of lime. Dig in grass cuttings in autumn instead of farmyard manure. The "blight" on the enclosed apple leaves is due to a leaf-curling aphis, Anuraphis roseus. Nothing can be done at present, but watch the affected trees in spring, especially after flowering, and spray them with nicotine soap wash as soon as aphides or leaf-curling and blistering is seen. When a number of toadstools occur on a lawn, water with ½lb. of iron sulphate dissolved in 1½ gallons of water at fortnightly intervals after rain has fallen. Rake over the surface prior to treatment to allow the mixture to penetrate.

Fruit Trees for a North Wall.

Will you tell me what bush fruits can be grown on a north wall? I read that the gooseberry season could be prolonged by this means, and if it is feasible I should like to try the plan with red and black currants also. Can barrels be used for growing fruit bushes, and, if so, what size should they be?—H. H., Darlington.

Gooseberries and red, white and black currants will do quite well on a north border. The gooseberries and the red and white currants can be grown as cordons quite well, but black currants do not usually succeed as cordons—not liking the "spur" pruning entailed—and are best grown as bushes just away from the wall. The berry season is undoubtedly extended by several weeks this way. Barrels are rarely used for fruit bushes, though there is no real reason why they should not be. The size of barrel to use is just a matter of convenience. The bushes do quite well in large pots, too, just as do apples, pears and plums, etc.

Transplanting Gentians.

I have a border of Gentiana acaulis 25ft. long, 1ft. deep, of very close growth, and healthy. There have been no flowers for the past two years. Can you suggest any means to remedy the fault? They are close to box edging (dwarf) which divides them from a gravel path. Would it be advisable to divide them? If so, should clumps be taken up, leaving the portions between undisturbed, or would it be better to thin them in their entirety? Please also say what time of the year it is best to transplant the gentians. —E. S., Peterborough.

We advise you to lift your gentian plants and divide them. Clumps might be taken up and thinned out and replanted, adding a little fresh soil to the border. This species requires fairly rich loam, and should be grown in a border where a trench has been dug some 2ft. deep and filled with well decayed manure. The plants respond particularly well to an abundance of lime. When transplanting, put the plants in firmly, and water round them if the weather is dry. Transplanting can be done at this time of the year.

Mildew on Vines.

The enclosed is from a vine about twenty-five years of age (cutting from Hampton Court) which has always done well, and never had mildew until now. I have dusted it plentifully with sulphur early in the season, but it seems hopeless for this year. The house is well ventilated; nothing else growing in it. Will you please tell me how to treat it to prevent a recurrence next year? Should I cut it all back now? The grass round about outside *has produced fungi lately which has never grown before, although surely there have been seasons as wet.—H. B., Worcester Park.*

In reply to your letter, the roots of the vines are, evidently, in a bad state; probably the border is not well drained and the roots are in a cold subsoil. In late autumn, remove the surface soil down to the roots and replace with good fibrous turves and bone-meal Of course, cold draughts on the vines will also result in mildewed berries.

Clover on Lawns.

Can you possibly tell me how to get rid o clover in a lawn? Two years ago we had the whole of the lawn taken up, because there was so much yarrow in it; and grass seed was sown. Now it consists principally of clover and yarrow. There was no clover in the first place, so I think that a mixture predominating in clover must have been sown. It is very disheartening after all the trouble and expense. I have been trying sulphate of ammonia on patches where they were not seen very much, and it has apparently killed the clover, but I do not know if it will be permanent. I should be glad to have your advice as to some really reliable remedy. Of the two I think yarrow is preferable to clover, but I do not want either—just fine grass only.—G. E. J., Loughton.

Clover will live on the nitrogen of the air, so care should be taken that any manures applied do not contain nitrogen. You cannot do better than apply, in November, a good dressing of sand and sifted soil, and in March 1lb. of sulphate of ammonia per 50 sq. yds. and 3lb. of rape dust. Do not use basic slag at any time. Yarrow is preferred in some gardens, as it thrives where grass fails. Sow freely, next March, seeds of Hardy Fescue grass, which is dwarf and reproduces throughout the summer. We also advise you to dress your lawn in spring with one of the special anti-clover fertilisers.

Manures for Heavy Soil.

Will you please advise me regarding the manuring of my garden? I have just taken this house and, so far as I can gather, the soil has never been thoroughly treated. The soil is very heavy and inclined to be damp, and there is a solid seam of clay about 2½ft. below the surface. Roses, lupins, coreopsis and pyrethrums seem to have done well. After rain, the ground, in parts, smells quite sour and is full of slugs and snails—also frogs, and I have found newts. I had thought of starting with a good dressing of lime. Will you please say which kind, how much per square yard, when and if I must put it on the lawn, which is fairly good? I should prefer to follow this with some kind of chemical manure.—H. W., Hale.

As much as possible should be thrown up into rough ridges early this autumn and immediately covered with lime—fresh—at the rate of 1lb. per square yard. Leave the soil ridged until next March, then level and surface dress with burnt soil and ashes from wood and rubbish fires. The best stimulant to growing crops, generally, next year, would be superphosphate of lime—2 oz. per square yard. Six ounces per square yard of ordinary lime would improve the lawn, if applied in November.

Treatment of Clay Soils.

Having recently taken over a new house at Kenton, I have accumulated a huge stack of solid clay lumps, and I should be pleased if you could offer me any advice on what use I can make of same. My own intention was to lay it down on a portion of my front garden, which I hope in due course to turn into a garage and drive. I was then going to let the winter frosts and rain break it up, if possible, and add road grit and wood ashes to it. Should you agree with this, what could I grow on same, or could you offer any other suggestion? This part of the garden faces due east, and gets some of the later-day sun.—W. A., Kenton.

Yes, treat the soil as you suggest. It should be left in a lumpy condition all through the winter, and not flattened out. In early spring add the road grit and wood ashes. In October sprinkle lime on the soil at the rate of 1lb. per square yard. Soil, so treated, would be suitable for practically any kind of crop, especially roses.

Malformed Pears.

I enclose a Louise Bonne pear which you will notice is malformed, the skin rough and the flesh granular in the malformation. Quite a third of the fruit on the tree is similarly affected. The tree was sprayed last February with Carbo-Krimp. I should be much obliged if you would kindly tell me what has caused this malformation, etc., and also what measures you would advise to prevent a like trouble occurring with next year's fruit.—H. B., Newton Abbot.

The damage to the Louise Bonne pear fruit you send has been caused by a small caterpillar or perhaps a garden chafer nibbling it when it was quite tiny. There is nothing else the matter with the fruit. If the tree is kept free from caterpillars and other springtime pests, you should have little trouble of this kind in future. The spraying with Carbo-Krimp—in January—we recommend you to continue for a season or two and it would help considerably if the tree were sprayed either with nicotine wash, or with lead arsenate shortly after the blossoms fall next year, as a preventive measure.

Grubs on Cherry Leaves.

Please find enclosed grubs on cherry leaves. During the last fortnight one tree in the garden commencing at the top, began to go brown and the brownness is getting lower, with every appearance of the whole tree being stripped; on examining we found grubs; hoping you will be able to name such, also giving a remedy to destroy them.—S. D., Leeds.

The pest attacking the cherry leaves is the plum and cherry slugworm. If left unchecked it will certainly spoil the tree. The remedial measures to adopt are as follows:—Spray the tree in July with arsenate of lead. Fork naphthalene into the top soil in autumn at the rate of about ½lb. to the square yard. If possible, let fowls scratch about under the trees in spring and late summer, and spray the trees in January with a tar distillate wash, such as Carbo-Krimp or Mortegg. If these measures are taken during the next twelve months you should get rid of the pest entirely. Should a slight attack occur after this, however, spraying with lead arsenate in July will check it completely.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2914 Saturday, October 8th, 1927 Price TWOPENCE

The Beautiful New Michaelmas Daisy, "Barr's Pink"

THIS is unquestionably THE FINEST PINK MICHAELMAS DAISY yet raised. The flowers, which are semi-double, large and open, are of a bright rose-pink with showy golden and bronze central disc. Excellent as a cut flower, lasting well in water, and as charming in artificial light as in daylight. The plant has an elegant and graceful habit, and is decorative from the middle of *September*, ht. 4½ft. Award of Merit at the R.H.S. Wisley Trials, 1925.

Extract from "Country Life":—

"Until lately one had to exercise a certain amount of imagination with the pink Michaelmas Daisies, which had more mauve than pink in their colouring. But now the pinks are really and truly pink, and of the newest varieties none is more prominent than Barr's Pink, which, with great beauty of rich colouring, combines a graceful habit, and one recognises that in this Messrs. Barr & Sons of Covent Garden have raised a variety that will long continue in the front rank of hardy flowers."

THE GARDEN

VOL. XCI.—No. 2914. OCTOBER 8, 1927. PRICE TWOPENCE.

GROWING FRUIT ON WALLS AND FENCES

WITH the increasing demand for fresh fruit anyone with even a very small garden can produce a quantity of fresh fruit if the right methods are adopted.

Most small gardens are enclosed by walls or fences of some kind, and instead of making these walls the most profitable, useful and interesting part of the garden, ivy and a few other climbers are promiscuously allowed to grow over them. More often than not they are sadly neglected and remain bare.

Nurserymen have reduced the training of fruit trees to such a fine art that different shapes of trained trees have been produced to give the maximum amount of fruit for the minimum amount of space required. These different shapes are known as fans, cordons and espaliers, and with a little commonsense on the part of the grower choicer fruit than is obtained from the usual bush or standard trees can be obtained.

Fan-shaped trees are generally used for cherry, peach, apricot or plum trees, but the three latter require a wall not lower than 10ft. in height. For the cherry a 5ft. or 6ft. wall can be used. Of these already mentioned the cherry and plum for home consumption are the most practical. If the cherries are Morellos, they grow excellently on a wall facing north; if the bigarreaus or sweet cherry, an east wall will suit them. Plums or gages, dessert or culinary, do well on the south wall. Fan-shaped trees of the foregoing fruits are planted not less than 15ft. apart, but the distance in planting is governed by the height of the wall in question. The border should also be as wide as possible in which the trees are planted, but excellent results have been obtained where the tree has been planted in a small border whose roots have run underneath a gravel path or lawn.

Single or double cordons are used for apples and pears, and are very suitable for the small garden. Single cordons are planted obliquely at an angle of 30°, facing towards the north so that the fruit can get the full benefit of the sun, and 2ft. 6ins. between the trees.

Double cordons, generally used for pears, are planted upright 3ft. 6ins. apart. Cordons are easy to prune if one realises the object is to produce a series of fruiting spurs the whole length of the stem. In July or early August pinch back the wood growths to the fourth or fifth bud, the sap of the tree is then concentrated into these buds, physiological changes take place within the buds, transforming them from wood to fruit buds. This shoot is the rudimentary fruiting spur. The quality of fruit obtained well repays the grower for the attention given to the production of the spurs.

Gooseberries can also be trained either as single or "U" shaped cordons or gridirons. The latter shape consists of two horizontal branches being taken from the main stem 1ft. above the ground and five or six upright cordons allowed to grow from the horizontal ones 1ft. apart. It is a very useful and suitable way of covering fences. Espalier trees are those from which several horizontal stems are taken parallel to and equidistant from each other from either side of a central stem. They are used for covering walls of any height, the distance for planting them being governed by the height, *i.e.*, for a low wall the length of the horizontal branches are developed, whereas on a high wall the main stem is developed and, consequently, more horizontals produced. Pruning is done exactly as for the single cordon, each horizontal stem being considered a single cordon.

The loganberry, Laxtonberry and other hybrid berries which, owing to the fan-shaped fashion in which they are trained, can be made to cover completely a wall or fence. They are very prolific and completely obscure unsightly places by their luxuriant growth. Pruning merely consists of cutting away all old fruiting canes not required and tying in the new suckers produced during the summer.

It is unnecessary to give here a list of varieties for any of the fruits suitable for training on the above methods, as any variety, dessert or culinary, will not only produce a larger but better quality of fruit. Moreover, lists of varieties to grow of the various fruits will be given in future articles on fruit later on in the planting season.

This Week's Work

For Gardens in the South and Midlands.

Make preparations for renovating herbaceous borders.
Lift and plant out rooted layers of border carnations.
Finish planting daffodils and hyacinths.
Remake lily of the valley beds.
Lift and store beetroots, onions and carrots.
Plant raspberries and grease-band fruit trees.
Lift and pot up chrysanthemums.
Lift bedding begonias and place in shallow boxes to dry off.
Finish transplanting wallflowers, Canterbury bells and other biennials.
Sow sweet peas in pots and germinate the seed in cold frames

Varieties of Sweet Peas for Garden Decoration.

THE Floral Committee of the National Sweet Pea Society recommends the following 24 varieties for general garden cultivation: Black Bess, blue-black; Bluebird, blue; Bonfire, bicolor; Charity, crimson; Charming, deep cerise; Delightful, pale cerise; Elegance, blush lilac; Grenadier, scarlet cerise; Ivory Picture, ivory; Joan Ryder, white; King Mauve, mauve; Magnet, deep cream pink; Matchless, cream; Miss California, deep cream pink; Mrs. Arnold Hitchcock, pale cream pink; Olympia, purple; Picture, cream pink; Powerscroft, lilac lavender; Sunset, rose; Supreme, pale pink; Warrior, maroon; Wembley, pale lavender; Youth, picotee-edged; 2 L.O., scarlet cerise.

This Week's Work

For Gardens in Scotland and the North.

Lift bedding begonias.
Grease-band fruit trees.
Plant raspberries in well prepared soil.
Protect vegetable marrow plants that are carrying fruit.
Lift rhubarb roots for forcing.
Feed leeks and Brussels sprouts with liquid manure.
Top-dress lawns and greens.
Transfer a few parsley plants to a cold frame.
Continue planting bulbs in bowls and borders.
Pot roses that are to be flowered under glass.
Lift and divide montbretia that is overcrowded.
Pot crowns of lily of the valley.

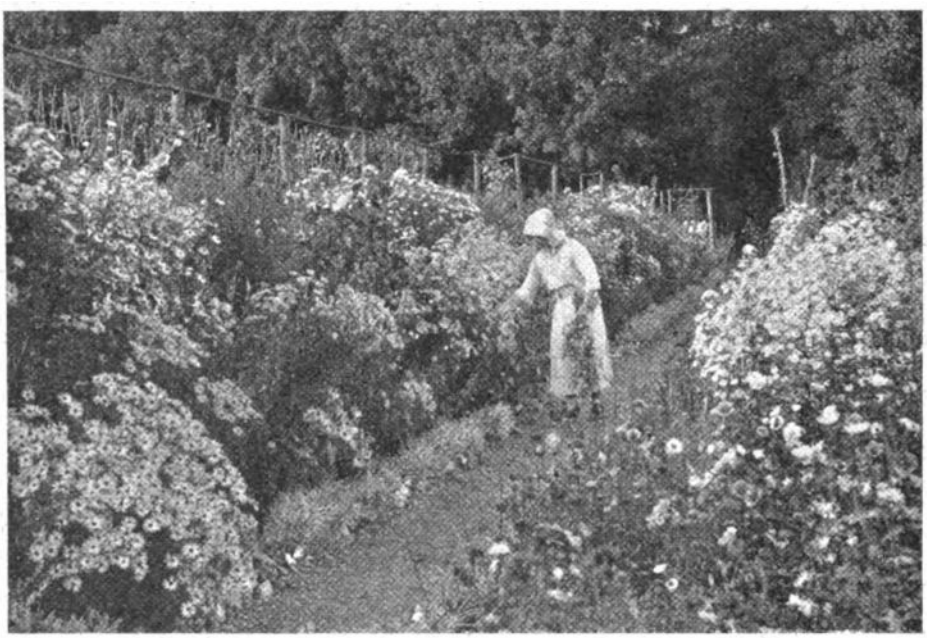
SOME OF THE BEST MICHAELMAS DAISIES

The Michaelmas daisies are now in full flower, and all amateurs should make notes of desirable varieties where they can be appreciated first hand. The following article describes a number of the newer sorts which are well worth planting during the coming weeks for blooming next year. The perennial asters are among the most decorative of our autumn flowers.

THE perennial asters, better known as Michaelmas daisies, are a group of hardy plants that ought to be represented in every garden. There are few more useful plants for an effective show of blossom in late summer and autumn no matter how they are planted, in beds by themselves or allied with other plants in the border. They are most accommodating plants and are little trouble to grow in almost any soil, so that even the veriest tyro in gardening can be sure of success with them. This year they are blooming well all over the country, and those who have been attending the autumn flower shows will not have failed to note the extraordinary advance which has been made in the production of new varieties. Not only has progress been made in improving the size and habit of the plants, combined with a more vigorous constitution, but the evolution of new colourings has been as wonderful as these are attractive. They, like many other new productions in other races of our garden flowers, stand as tribute to the great skill of our plant hybridists, who must possess taste as well as considerable knowledge.



A PICTURESQUE BORDER OF MICHAELMAS DAISIES.

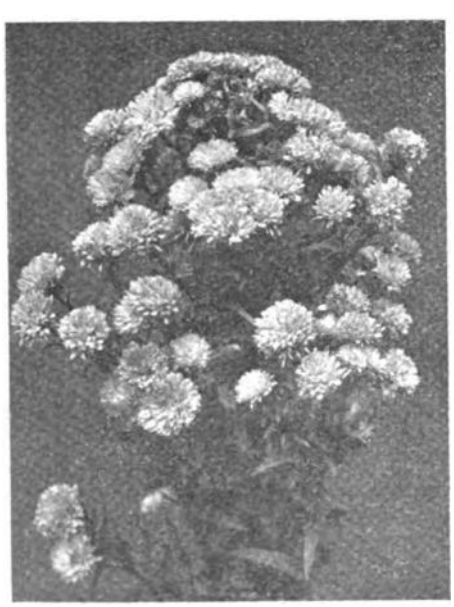
All amateurs should plant clumps of perennial asters to brighten the garden in the autumn months.

The perennial aster group comprises several sections, and any consideration of new varieties must consequently follow on such lines. One of the largest and one of the best sections of the group for general purposes in the garden is the Novi-Belgii. This section contains the majority of the large-flowered varieties, which are particularly robust and upright growers and very floriferous. Among the newer varieties which it contains are Nancy Ballard, which is of neat habit and carries rounded heads smothered with semi-double flowers of a rich purple to mauve colour; Anita Ballard, a very floriferous variety, of neat floral habit. The broad ray florets are of a delicate shade of cornflower blue and are beautifully incurved, which lends considerable attractiveness to the flower. Then come two of a similar nature, only differing in size. These are King Albert, a dwarf with semi-double lilac flowers, and King of the Belgians, of majestic stature and carrying large semi-double blue flowers. Two good whites in this section are Perry's White and Wells' White. Both are erect-growing varieties with pyramidal habit, and the large pure white flowers are of fine form. Sam Banham is another good white with the large flowers of Climax, of which it is a seedling. Occasionally the flowers may be tinged with pale pink. Of a more lilac tone there are two good sorts in October Dawn, of compact habit, only reaching some 2½–3ft., with lilac mauve blooms, and Queen of the Lilacs, growing to some 4ft., with flowers of a clear lilac blue. Two of the most charming Michaelmas daisies there are come in this section, and the one forms a companion for the other. The one is Little Boy Blue, the other Little Pink Lady. Both are dwarf growers, seldom reaching 2ft., and their dainty little erect pyramidal shoots are wreathed in neat button-like flowers of a bright blue in the case of the former and deep pink in the latter. They are, indeed, the miniature gems of the group and should certainly find a place in any representative collection of asters. One of the best pinks in this section and, in fact, in the family, is Ethel Ballard. The shoots are strong growing, erect and carry large single pink flowers all the way up. Queen of Colwall is a tall mid-season variety with large semi-double blooms of pale mauve.

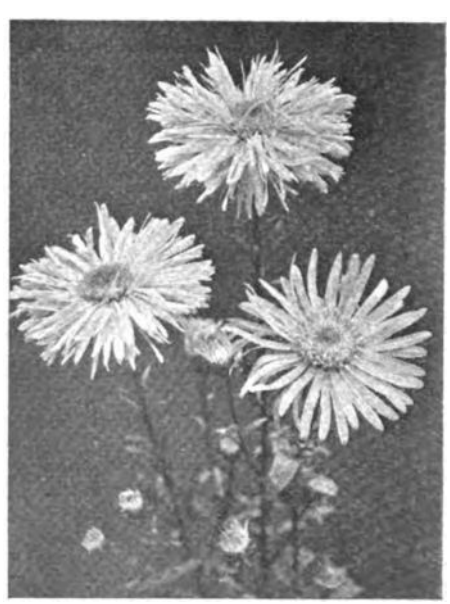
The finest aster of this group, however, is a newcomer by the name of Queen Mary, raised recently by Mr. W. Wells. The flowers measure some 3ins. across and are of a wonderful rich blue shade. They are carried in loose pyramidal trusses which are most decorative both for the house and the garden.

Another good garden section is the Amellus, containing such well known varieties as King George, the best violet blue yet raised, and the very dark blue Ultramarine. Beauty of Ronsdorf is another worth growing for its large lilac-pink flowers, but the best pink of the group is Wells' Favourite, an elegant variety and very free-flowering.

A few varieties of the ericoides section are worth growing in the garden for the sake of their attractive heath-like foliage. A selection of varieties of this section might include the following: Chastity, a late-flowering variety with mauve flowers; Coquette, of a pale lavender tone; Decoration, pure white; Enchantress, pale blue;



THE NEAT BUTTON-LIKE FLOWERS OF THE DAINTY ASTER LITTLE BOY BLUE.



THE GIANT ASTER QUEEN OF COLWALL WITH THE VIOLET BLUE A. AMELLUS KING GEORGE.

Digitized by Google

Hon. Edith Gibbs, with lavender flowers; and Twilight, an attractive bluey white which, under certain lights, appears a beautiful silvery grey. There are many more excellent sorts in this group, but the above will be found representative of the range of habit and colour which is to be found in this section alone.

The only other section of garden importance is that of the Novæ-Angliæ, and the one variety of this division which every garden should contain is Barr's Pink, one of the most outstanding plants of recent years and which is illustrated on the front cover this week. With its gorgeous saucer-like blossoms of a deep rose pink colour enhanced by the bronze eye, carried on stiff, erect stems, it makes when planted in clumps in the garden one of the most effective displays to be seen during the autumn. It is not expensive and is now easily obtainable, and these two points, combined with its beauty of habit and flower, should recommend it to all garden lovers.

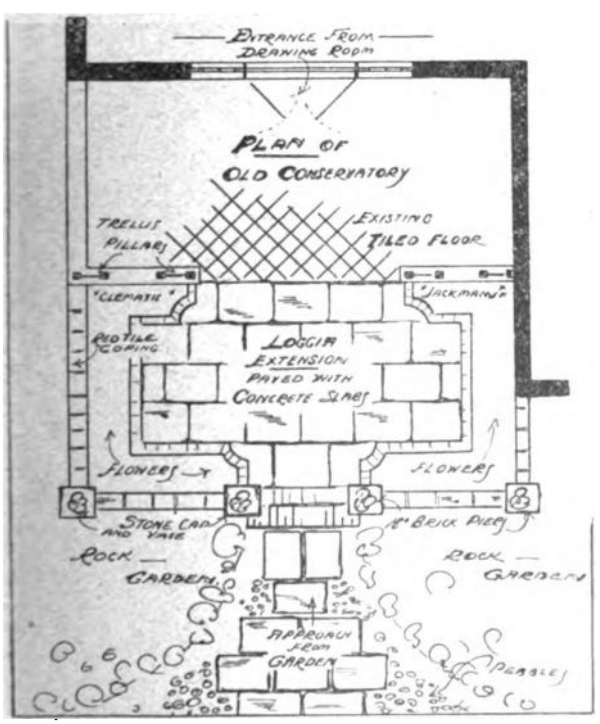
The only point about the growing of Michaelmas daisies in the garden that calls for special mention is the staking. The beauty of a plant can be made or marred by the method of staking. Do not insert one stout stake and tie all the shoots together in a bunch. The shapely habit of the plant is lost by this method. Use at least three stout stakes and place the raffia round the stakes, enclosing the plant at the same time. As growth takes place the foliage will soon cover over the raffia and hide the stakes from view completely, and, in addition, this method will preserve the artistic grace of the plant. Prepare the ground well for receiving the plants and insert them firmly in the soil. If the planting cannot be undertaken during the next month, then it is best to wait until March, which is both a convenient and a sure time to plant Michaelmas daisies. At least a few varieties of one of the various types should make a strong appeal to the gardener who wishes to add brightness to the garden border next autumn, and as planting time is now at hand a selection of these time-honoured but nevertheless beautiful daisies should be made at once. T.

A USE FOR AN OLD CONSERVATORY

MANY houses of the pre-war type, contained a small conservatory, which was usually arranged in conjunction with one of the sitting-rooms; many of these have unfortunately become obsolete for reasons which must differ in every individual case; probably the structure suffered in point of aspect, or of accommodation, bad construction, or a combination of each. However, such an abandoned structure can easily be transformed into a comfortable sitting-out place or loggia at a comparatively small cost, forming as it were a compromise between house and garden, thereby adding another attractive feature to the garden scheme.

The accompanying photograph and plan serves to illustrate the method employed in the reconstruction which is on very simple lines. The existing brick base is merely lowered to a height of 15ins. from the floor level, the central opening being enlarged to give a more airy appearance from the interior. Four pillars support the roof and are composed of square mesh trellis, 1½ins. by ½in., framed into 4in. by 3in. deal posts; these pillars are dowelled into a York stone coping, which, together with the dwarf wall already referred to, makes a suitable ledge for books or even a seat; the pillars, if painted white, look very attractive when clothed with the beautiful clematis of the Jackmanii variety which can be planted in the narrow border as indicated on plan.

AN OLD CONSERVATORY TRANSFORMED INTO A COMFORTABLE LOGGIA.



A SUGGESTED PLAN FOR UTILISING A CONSERVATORY.

The glazed end of the old conservatory can either be left intact, or altered to correspond with the new front; in many cases it will be essential to let it remain and act as a wind screen, in which case the glass can be simply stippled to give more seclusion.

The roof of a very dilapidated structure will probably need renewing; if a glass roof is still desired, one cannot do better than adopt one of the patent metal glazing bars now on the market; this system makes a durable and watertight roof; it has many advantages over the construction with wood bars, the chief being that no periodical painting is necessary either on the inside or out.

Leading from the loggia proper, an extension is often required, not only to accommodate more chairs in the open, but to complete the scheme by an arrangement of small beds for the reception of bedding plants near the house; the floor of this extended portion is paved with small rectangular concrete slabs, pre-cast in moulds and laid with an open joint; bricks laid flat forms the curb for the narrow beds, and this item alone leaves much to the originality of the owner in question. The weathered bricks that were removed from the base are used for the dwarf walls and piers forming the enclosure; 2in. York stone is used as caps for the brick piers and 1½in. weathered paving tiles as a coping for the low walls. This little extension judiciously planted with a few choice flowers produces a charming effect; personally, I like to include many fragrant flowers in the vicinity of the loggia, the amenities of which can only be judged when the air is redolent with the combined perfume of these delicate scented blooms; there is, however, a good selection of subjects suitable for both spring and summer flowering and are frequently referred to in the pages of this journal.

Hydrangeas in oak tubs placed on top of the stone caps should give just sufficient colour and a greeting of flowers at the entrance. This type of loggia or garden room situated in a favourable aspect, not only makes a comfortable retreat, but a delightful place for meals in the fresh air. As this method of transforming a disused conservatory is quite simple and inexpensive, it is well worth consideration for the future improvement of the garden scheme. G. W. H.

ROCK PLANTS FOR EVERYONE

In this article a selection of plants that are most suitable and desirable for the small rock garden is given. All are bright and attractive and moreover easily grown. The majority like a sunny and open position. By planting clumps of a few of these this autumn you will have a fine display next spring.

THE rock-loving plants that yield the greatest measure of success with amateurs are notable sunlovers, and it is to this section that the beginner can turn with every confidence, their main characteristics being that they are perfectly reliable, generous in flowering, unquestionably hardy and not costly to procure. In small gardens, and with the plants that are named, there is never the same urgency to employ each kind in masses, although a few of the most effective should always be given this prominence; the majority, however, in time swell out and form a mass in themselves.

No rock garden should overlook the merits of Arabis albida fl.-pl., aubrietias, all varieties and Alyssum saxatile and its variety citrinum, and also the double form, their only drawback being that they are too common and, if I may say so, too easy to grow. Nevertheless, they are the glory of the rock garden and dry wall in spring, and their perennial and prodigal wealth of blossom will always command admiration and win for them a place of honour in our gardens.

The perennial candytufts (iberis) become perfect snowdrifts when in flower; Little Gem, Snowflake and correæfolia are three of the best. Erysimum pulchellum is a pretty, flat evergreen with flowers of gold, very freely produced during April and May. Chieranthus Allionii should be placed close to the last named, as the striking orange of its flowers shows to distinct advantage against the gold of erysimum.

Phloxes, like amœna and reptans for early flowering, and the forms of subulata for a later display, give a wide range of colours from white to deep rose, while there are several with flowers of a delicate lavender shade, such as G. F. Wilson (lilacina).

Androsace sarmentosa is one of the best and certainly the easiest to grow of this beautiful group; it throws out delicate runners like a strawberry plant, and if these are pegged down and nice gritty soil placed under the little plants they soon root and take up an independent existence.

Dianthus is a genus to conjure with; try a good strain of seed of D. plumarius and plant the seedlings in dry-wall, rock garden or sharp-pitched slope and the feast of colour will be a revelation. Among the species that can be recommended for a maiden effort are cæsius, deltoides or graniticus, neglectus, alpinus, arenarius and microlepis.

Campanulas are important and should include G. F. Wilson, pusilla, in three colours, and muralis for early summer, and Profusion, haylodgensis and varieties of carpatica to flower later.

Gypsophila repens (white or pink) and Saponaria ocymoides (rose) with its variety splendens (crimson) are glorious plants to drape over the face of a rock, and the flowers are massed in such a way as almost hides the foliage from view.

DWARF PHLOXES AND CANDYTUFT ARE TWO PLANTS NO ROCK GARDEN SHOULD BE WITHOUT.

DIANTHUS AND A FEW OF THE HYPERICUMS ARE AMONG THE BEST OF SIMPLE ROCK PLANTS TO GROW.

Several of the hypericums, with their Rose of Sharon flowers, are among the best of rock plants. H. Coris forms neat, erect, heath-like bushes, whereas repens and reptans are prostrate in growth; the flowers in each instance are yellow and the centres are quite filled up with the elegant filaments of the anthers.

Every rock gardener should attempt to grow Lithospermum prostratum and its variety Heavenly Blue. At first effort you may possibly fail; nevertheless try again, and ultimately succeed, for the gromwell (lithospermum) blue is in this instance faultless. Plant them very firmly indeed, for they are really hard-wooded shrubs, although so dwarf, and if the natural soil be limestone or chalk, remove it and replace with soil free from lime.

Lychnis Viscaria splendens and Œnothera riparia are useful and effective plants; the flower stems are borne erect, and this is of some value when placed among flat-growing plants. Many of the silver saxifrages are useful in the same direction; those that may be specially mentioned for beginners are SS. Aizoon rosea and A. lutea, Cotyledon pyramidalis, Hostii, lingulata and lantoscana.

Mossy saxifrages soon form dense tufts of foliage, and from April until June they produce abundance of flowers, which are either white, pink, yellow, or crimson. S. hypnoides is one of the quickest growing, S. muscoides atropurpurea has small pink flowers, and S. sanginea superba is, perhaps, the best red. Androsaces, if given an open sunny position, grow well and flower freely; Erinus alpinus is suitable for a crevice, and Polygonum affine (knotweed) is best for the rockery edge.

Tunica Saxifraga and Silene alpestris are very dainty for a crevice between stones; and Thymus Serpyllum (especially the varieties coccinea and alba) and T. lanuginosa are charming for their scent.

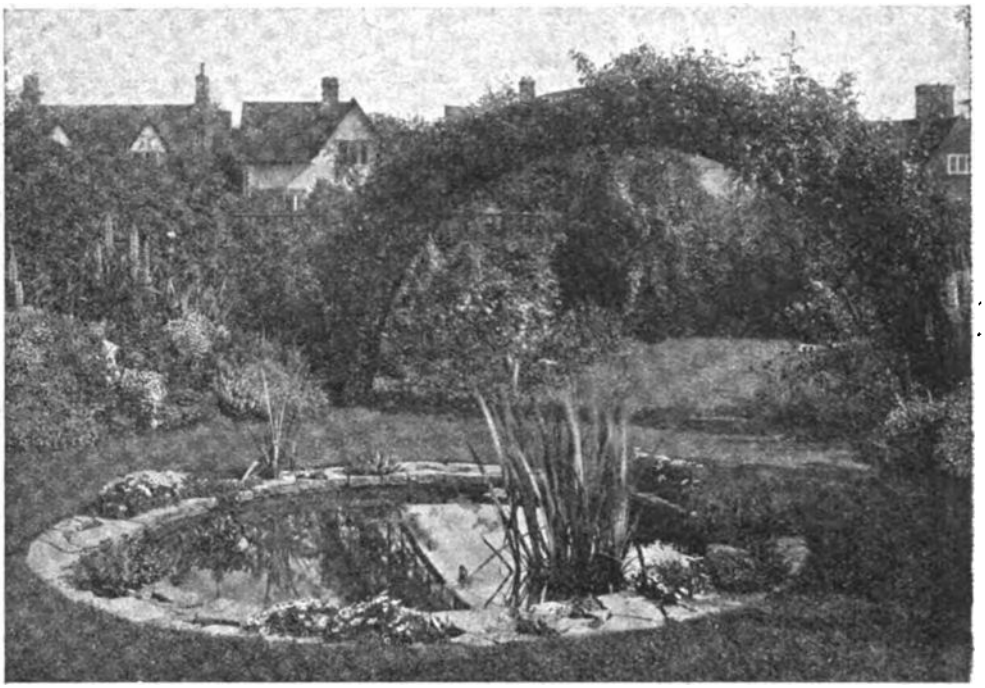
AN ATTRACTIVE GARDEN POOL

How one can be made in a simple and inexpensive way. A pool of even miniature size provides a certain amount of additional charm and interest in any garden.

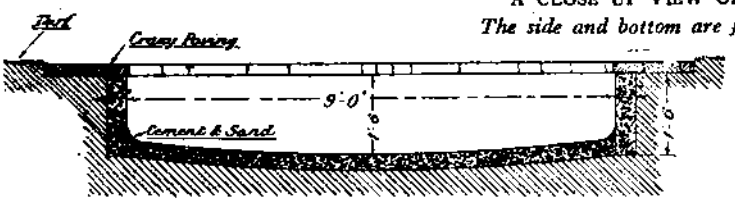
THE accompanying two views of my garden will, I think, be of interest to many readers who have just a small plot of ground, and who desire to make it attractive. Often a pool is desired, but the amateur experiences some difficulty in determining how to construct it himself at small expense. The manner in which I have constructed mine is very simple, and does away with a woodwork mould.

On the spot selected for the pool a circle 9ft. in diameter was scratched on the grass. This was done by sticking a peg in the ground and attaching to it a 4ft. 6in. length of string, with a small screwdriver tied to the end. A second, outer, circle was then struck 9ft. 9ins. in diameter, thus giving a distance of 4½ins. between the two circles. The turf was removed between the lines, and the soil dug out to a depth of 18ins. The space of 4½ins. allows just sufficient room for one's arm and a trowel or other garden implement suitable for removing the soil, and for making the sides and bottom of the trench as smooth as possible. The trench thus made was filled with concrete, and when set (after two days) the turf and soil within this concrete ring were removed. A 3½in. thickness of concrete was then placed in the bottom, as shown by the diagram. To make quite sure of the pool being watertight, a fillet of cement and sand was put round the joint, but I do not think this was necessary.



A CLOSE UP VIEW OF THE POOL BRINGING OUT DETAILS OF ITS CONSTRUCTION.

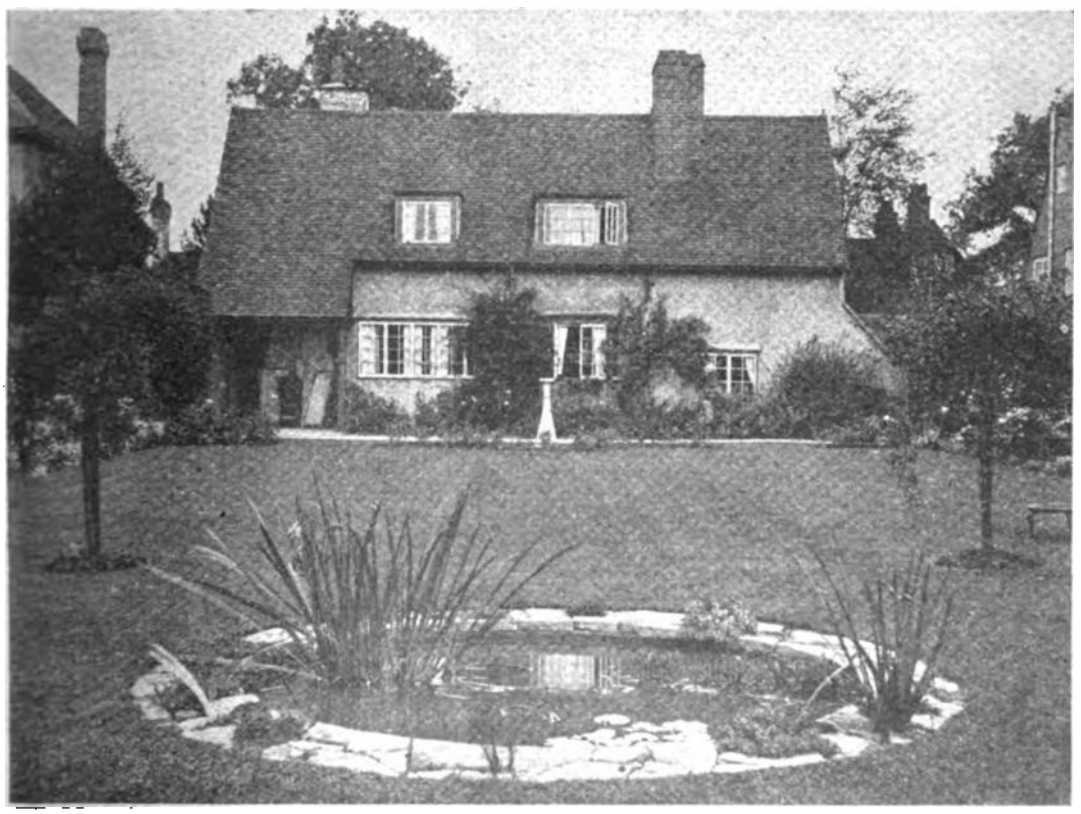
The side and bottom are formed with concrete, while the rim and edging are finished with stone planted with dwarf-growing subjects.



The concrete was made by mixing gravel with Portland cement, in the proportion of about 6 to 1. The amounts required for this pool were 1½ loads of gravel, and one-sixth of this quantity of Portland cement. A rough platform was made by nailing some boards together, and on this the gravel and cement were well mixed together. Water was next sprinkled on the heap from a watering can with a rose, and the whole turned over and over, until a semi-liquid mass was obtained. This was then put in place, finished off smooth with a trowel, and allowed to set. Afterwards the rim of the pool was completed with stones laid in cement, flush with the grass, spaces being left in which to put a little earth for the growth of rock plants, etc. Fish live and breed in the pool, and the lilies and irises grow in boxes filled with soil.

Quite a number of low-growing creeping and cushion plants were placed round the margins of this pool, and these are now well established. They provide a fine display of colour and blossom during the spring and early summer. As time goes on, additions may be made by planting one or two aquatics and other moisture-loving plants. B. C. D.

['This is an arrangement that many of our readers might like to carry out for themselves. It can be done in a small space and at little cost.—ED.]



THE POOL IN RELATION TO THE HOUSE, SHOWING THE BEAUTY OF A LAWN SURROUND.

THE BUSY MAN'S PAGE

Autumn Digging.

CONSIDERABLE benefit is derived by exposing the soil—especially clay soil—to the action of the weather during the winter. The rougher the surface is left the better, so that the frost can get well in to pulverise the soil and produce a fine tilth for the reception of the seed in the spring. The birds also have a chance to get at the harmful grubs. Digging should be deep and thorough, and the subsoil broken up with a fork, but left in position. To do this successfully a wide trench is necessary. A practical method is as follows: Divide the piece of ground to be dug into two equal parts longitudinally. Dig out a trench at the top of one section, and place the soil at the top of the adjoining section. Proceed to the end of the first section and fill in the trench with soil dug out to get a trench on No. 2. The soil from No. 1 will then be quite handy to finish off without the need of a wheelbarrow.

By having a wide trench there is an opportunity for digging in leaves, stalks and other refuse that will rot and thus produce humus matter. For digging clay soil a fork is generally found more serviceable. Roots of twitch, cornbine, etc., should be carefully removed and burnt. Surface growth should be pared off and put on the bottom of the trench, but any weed about to shed its seed should be burnt.

Present Treatment of Border Carnations.

OCTOBER is the month during which it is customary to lift carnation layers with the object of planting them out or potting them up. Many growers are content to transfer the rooted layers direct to their permanent quarters outdoors.

It is sometimes a better course, however, to take rather more trouble and pot up the rooted layers as soon as they are ready to be dealt with.

A suitable compost may be made up of good turfy loam, leaf-mould and coarse silver sand or clean road grit. Of the first-mentioned ingredient take 3 parts, and of leaf-mould and coarse sand 1 part of each. These should be thoroughly mixed, and the prepared compost kept in a cool shed to maintain it in a good workable condition until it is required for use. Suitable pots into which to place the rooted layers are those 3ins. in diameter.

The plants should be transferred to a cold frame, standing the pots on a layer of sifted ashes or coke breeze.

CARNATION LAYERS ROOTED AND READY FOR LIFTING.

The frame should be kept close for a week or ten days until the rooting process has recommenced, when air should be admitted. The frame-lights should never be closed subsequently; the plants must always have air if they are to be maintained in a healthy condition throughout the late autumn and winter.

If the layers are to be planted outside directly then moderately firm ground is essential in the case of borders in the garden, but such firmness must not be obtained by treading. It should settle down gradually, and is all the better for being well prepared and left untouched several weeks prior to the date of planting. Any manure that is used should be buried quite 8ins. below the surface of the soil, so that the roots of the carnations will not come into direct contact with it before next spring, when they become very active. Well rotted manure and gritty soil, mixed, form a good food for the plants in all ordinary garden soils.

If the carnations are to be grown in beds, fix the line 20ins. from one side of the bed and carefully plant the row of carnation layers not nearer than 1ft. apart; then fix the line 9ins. from the edge of the bed and plant the row of layers at the same distance apart. Thus half the bed is planted without the planter treading on the soil of it; he stands in the alley. The two rows of plants on the opposite side of the bed can be dealt with in a similar way by standing in the alley on that side. The soil should be raked down finely before any planting is done, and at that time it should be fairly dry, so that some may be pressed with the hands firmly to the roots without injuring any of them. One application of water through a fine-rosed watering-can should be sufficient at this time. If there are wireworms in any part of the garden, take the precaution to dig in "Vaporite" before the carnations are planted.

Renovating Faulty Lawns.

THE present time is an ideal one for doing lawn improvement work. Turves can be lifted, cleaned and relaid where necessary; surface dressing may be applied and similar work done, and then there will be ample time for the lawn to recover before it is again required as a setting for summer flowers. The most faulty lawn is probably the one in which couch-grass grows. The more one mows such grass the more rapidly it spreads. Not only does the top growth spread, but the roots—or runners—under the surface. Finer grasses cannot compete with this coarse one, and, where the latter has become established, it is useless to attempt to improve the lawn by extracting the roots. This simply cannot be done. The only way is to take up all turf, dig the soil below it and extract the roots, every tiny piece, and burn them. When this has been done the soil should be levelled again, when it will be ready for new turves or for grass seeds next March. Do not wait until late in the winter to clean soil for new lawns of these weed grasses, as, when the soil is forked up now and bared, seeds of weeds in it will germinate, and in the seedling stage, be destroyed by using the Dutch hoe. By the time that grass seeds should be sown the soil will be quite free from weeds and their seeds.

A YOUNG PLANT READY FOR POTTING AND ONE POTTED UP.

Many lawns are simply too poor to support grasses in a healthy state. These should not be covered with organic manures, which often, in this form, do more harm than good. A mixture of good soil, leaf-soil, wood ashes, burnt soil and bone-meal, all passed through a ½in. mesh sieve, will prove highly beneficial if applied at the rate of one barrow-load to each square rod of lawn. The soil should form the greater bulk, of course; 1lb. of bone-meal per barrow-load and the other ingredients in proportion will do well. If the grasses possess plenty of roots but are pale in colour, inclined to yellow, a mere sprinkling of fine soot in powder form will do a lot of good. The mossy lawn may be improved by applying 4 oz. of powdered lime per square yard, now. The swampy lawn should be drained; there is no other remedy so efficacious.

Storing Dahlia and Begonia Roots.

A HARD night's frost blackens the foliage of dahlias and begonias, and this must be taken as a signal that they are to be lifted at once for storage. Carefully fork them up, taking care not to break or bruise the roots, shake much of the soil from them, and take under cover. In a few days the dry soil may be shaken away, the stalks cut and the roots laid aside for a further period. When quite dry, the begonia will part company with its stalk; but a portion of the stalk of the dahlia may be left and a label tied to it if necessary. After this the roots should be placed in a box and dry sand is then poured over and round them; this prevents excessive shrivelling and keeps out frost. Although frost is undoubtedly harmful to the roots, damp is frequently a worse enemy. The sand in the box, too, must not be allowed to get damp at any time; but should it by accident become moist, turn out the roots, let them dry, and rebox in sand once again until spring. The roots are generally safe anywhere under cover in the above way, and the best plan is to store them in a frost-proof shed.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Weeds on Lawns.

Hints on the Treatment of the Different Kinds.

A LARGE variety of weeds are found on lawns. They fill the lawn with leaves that are often more juicy than ordinary grass, and which consequently tend to soil tennis balls, etc., and so render the lawn less suitable for games of every description. The following are some of the most common of these weeds.

Buttercup.—Several kinds of crowfoots or buttercups are found on lawns, and all are difficult to eradicate. The best way is to spud out each plant when it is noticed. Frequent dressings of lawn sand will also rid the lawn of these weeds. Should a large patch be present, it is advisable to remove the turf entirely and replace with fresh.

Daisies.—Raking or grubbing the plants from the ground with patent appliances is sometimes advocated for this weed, but the plants when removed must be lifted out of the soil, not merely cut off at the top. A good preparation of lawn sand, which should be applied so as to cover the leaves completely, is the best for these weeds. If a bare patch is left after the application of the sand, it can be re-sown with grass seed, which should, of course, be protected from birds.

Dandelions, Plantains and Docks.—These are difficult to destroy unless the roots are removed entirely. A few drops of vitriol dropped into a small hole made in the root will destroy the plants, but care must be taken not to drop any on to the grass, or to get any on to the hands or clothes.

Bird's Foot Trefoil.—This trefoil has flowers tinted red and yellow. It is easily destroyed either by pulling up when the soil is moist, or by applying a little sulphate of ammonia, lawn sand or common salt to the root stump after cutting off the top.

Clover.—This is not always objected to, but is undesirable on lawns used for tennis and other games. To encourage grass and gradually eliminate clovers, sprinkle finely ground sulphate of ammonia, or nitrate of soda (half an ounce to each square yard) on the lawn every three or four weeks.

Moss.—Bad drainage or poor soil will either of them produce moss on a lawn. If not checked it will quickly ruin the grass. First rake out the moss with an iron toothed rake. Then give a good dressing of lawn manure, mixed with some fine fresh soil. Repeat this dressing once or twice until the moss is quite gone. Ground lime applied at the rate of two ounces to the square yard will sometimes destroy moss. If the moss is the result of bad drainage, lift strips of the turf, dig trenches, and put in clinkers or bricks to improve the drainage, and then replace the soil and turf. Each trench so made would drain the soil for about 6ft. on either side.

Fairy Rings.—These are the result of fungi, which produce circles of dark green grass, inside which are circles of dead grass, with inner circles of dark green. Copper sulphate solution, one ounce in a gallon of water, will destroy them, but is injurious to the grass. Sulphate of iron, followed by lime, is sometimes effective. A liberal dressing of lawn manure for two seasons will have a good effect.

Sorrel appears on lawns where the soil is damp. An application of lime, repeated if necessary, and followed by a dressing of lawn manure, will usually encourage the grass to choke out the weed, large plants being spudded out.

Mouse Ear Chickweed, Self Heal and Yarrow are weeds that are best killed by a dressing of lawn sand, unless they are few in number.

This season of the year is a good one in which to attack most of the lawn troubles. The soil is moist, and large weeds can be pulled out whole in many cases. Slow acting fertilisers applied now will benefit the lawn all through next season. They are of great importance. Few gardeners realise what an enormous amount of food value is wasted by the weekly cutting and clearing away of grass clippings. Unless this material is replaced in the form of fertilisers, the soil becomes gradually impoverished, and the finer grasses fail, thus allowing rank weeds to take their place.

A Well Filled Garden.

CLEMATIS, including the varieties Jackmanni and Henryi, as well as other climbers, are used with charming affect against a stucco wall in the garden illustrated herewith. Clematis is particularly successful as a town plant, and thrives even in districts where smoke will not allow roses to display their full beauty. A heavy loam is the most suitable soil, and to this should be added a liberal quantity of well rotted manure. The sub-soil should be well broken up before planting is done, bearing in mind that defects in the soil cannot afterwards be rectified without disturbing the plants. All clematis are lime-lovers and a liberal dressing should be applied before planting.

The pruning of clematis is important. Jackmanni should be pruned in early winter, cutting well back to the old wood. Varieties which flower on the wood of the previous season, such as montana, should be pruned in early spring, February or March, cutting out weak shoots, but not cutting back to the old wood as in the case of Jackmanni.

Montbretias that Deteriorate.

NO plant responds better to cultivation than do the montbretias. These popular flowers give the best results in a town garden if lifted annually, after flowering, and replanted. Left from year to year without care, the plants deteriorate and the flowers become but puny things. Large sprays of richly coloured flowers should be aimed at, and, to achieve this, lift the corms now, and replant them 3ins. deep and 4ins. apart. Groups or masses show to much better effect than single plants.

Plants for the Rockery.

"CAN you tell me," asks a reader, "the names of six easily grown alpine plants? They must be true mountain flowers, but suitable for brightening the little back yard rockery." Here are six gems of tufted habit, which will grow in the poorest of soils: Epimedium roseum (barren wort), Dianthus deltoides (pink), Campanula pusilla (blue or white bellflower), Sempervivum arachnoideum (cobweb house leek), Sedum (stonecrop), Saxifraga umbrosa (London Pride). Grey, woolly leaved alpines and encrusted saxifrages should be avoided in smoky districts, as they usually die off during the winter.

A GARDEN WHERE PLANTING HAS BEEN DONE SKILFULLY AND CAREFULLY TO PRODUCE A WELL FURNISHED EFFECT.

A Violet-Scented Iris.

A PRETTY little bulbous iris, which blooms as early as February in the open, is Iris reticulata. It is a dainty little plant, growing only to the height of 6ins., and is scented like the violet. The bulbs should be planted now, in clusters, a few inches apart and 3ins. deep. It is ideal in the rockery, lending colour when other flowers are rare. It will grow also in bowls or pots, if treated in the same way as the more ordinary bulbs.

Lifting Beets.

BEETROOTS are tender and spoil easily in the frost. They should, therefore, be pulled and stored early. Twist the leaves off, but do not wash off the soil. Pack the roots in sand or sifted coal ashes. Keep them cool and they will last all through the winter. Fully grown carrots can be treated in the same way.

THIS WEEK IN THE FLOWER GARDEN

A Small Water and Rock Garden.

THE accompanying illustration shows a portion of a very small rockery in a North London garden. A cask sawn in two has been sunk into the ground about 12ins. and mould and stones placed round the two tubs. A lovely small pink water lily grows in one tub and a beautiful little white one in the other. Some of our native rushes have made themselves very comfortable in the water also.

Among the surrounding stones grow all sorts of beautiful plants, some small heaths, among them one from the Yorkshire moors and a delightful winter blooming one, which with the help of a floriferous Christmas rose makes the little rockery very interesting during winter. Some native ferns, thrift from the Mumbles, a yellow mimulus from the river Chess, are interesting reminders of past days in the country. Dwarf heaths, rock roses, Campanula carpatica, blue and white fuchsia, gazania, Persian tulips and many other bulbs and plants flourish in this small rockery.—E. M. SPENDER.

A MINIATURE POOL AND ROCKERY IN A SMALL SUBURBAN GARDEN.
It is an idea that many amateurs should try since it offers a wide field for experiment with many interesting and beautiful plants.

Planting Roses.

THE best time to plant roses is at the end of October or the beginning of November while the soil still retains some of its warmth. The ground for roses should be rather on the heavy side, a good clayey loam being ideal. For the best result it pays to trench the border, incorporating some well rotted stable manure with the bottom spit of soil. Trench the ground as soon as is possible, thus giving it a chance to settle before the actual planting operation is performed.

The trees for planting should have their roots trimmed with a sharp knife, cutting away any bruised or decayed portions. Dig out a hole sufficiently large to accommodate the roots and spread them out, working in among them good garden soil or a compost of loam and leaf-soil, with a 5in. pot of bone-meal added to each barrow-load of compost. Do not plant deeper than 1in. above the starting point of the root system. When planted, firm by treading, and cover the ground with a top-dressing of strawy manure as a protection against frost and loss of moisture. Bush roses for bedding purposes should be planted 2ft. apart each way, more for the most vigorous varieties. Standards should be planted at distances suitable to the requirements of the space to be occupied.

I do not advocate pruning at planting time. Pruning should be left until the commencement of spring, *i.e.*, about the end of March.

Standard roses will require staking. A piece of ¾in. iron pipe cut off to the required length makes an excellent stake and is everlasting.

Perennials for Poor Soils.

IT ought to be stated that the term "poor soil" is scarcely permissible among respectable gardeners, because it is, or ought to be, the aim of everyone to render the poor soil at least passably good. It must be admitted, however, that there are many gardens of poor soil; a porous, hungry and always dry loam may lie over a gravelly subsoil; a hard, granite-like surface may bespeak a humus-less layer underneath; or what was once a good loam may have been "cropped to death" and be now almost useless. Of course, the first idea is to make the poor soil better by digging, by working in as much humus-forming material as can be obtained by the judicious addition of lime, turf and leaf-mould, and in all the other regular ways. Then choice things will grow there and the border be no longer an unsatisfactory one. A poor soil reflects its poverty in the plants which grow in it, but there are some perennials of special merit which do very well in face of all the difficulties. Among the best are the perennial campanulas, dwarf kinds and tall; they may not grow very freely, but in season they clothe themselves in blossom to a remarkable extent. The androsaces are also splendid and very pretty when in and out of bloom; but so, too, are others generally classed as rock plants, of a similar nature, like several saxifrages, creeping linarias, Hutchinsia repens, Dianthus cæsius and D. deltoides, the arenarias, the smaller phloxes and hundreds of others, generally kept apart for the rockeries. Leaving these smaller kinds alone, however, I must mention some of the larger-growing perennials. The common galega is remarkably fine under such adverse circumstances; Zauschneria californica is quite good; the sunflowers of the rigidus type, moderately fine; Gentiana acaulis, if it can be got to settle, will bloom well; Erigeron speciosus is really qtite excellent; the platycodons have proved a great success; the Rose of Sharon makes a brave show; the more common heucheras are always passably satisfactory; red-hot pokers, if fed when about to come into bloom, are really pretty and fairly full, even when dwarfed in size; doronicums will do well in the moisture, which is generally more plentiful in spring; and one or two species of scutellaria. The bulbous plants must not be overlooked; true, we admit, the majority rapidly deteriorate under adverse conditions, but they will flower more than once, and many kinds can be introduced according to taste. One point I must bring out, after seeing my own results and the efforts of others; the old varieties are often the hardiest, and newer kinds, in some cases, prove disappointing. New varieties of plants, due in great measure to sporting, which may be stimulated by kindly treatment, either grow in a very forlorn fashion or fail entirely in poor soils; hardy old things, not easily obtained from modern nurseries, do well and give a show which in mass is always fairly good. These notes may encourage others who have a border which seems too poor to be worth much trouble, for every corner of the garden can be filled with some plant, and a bare border ought not to be allowed.—CLYDESDALE.

Some New Phlox.

DURING recent years, when the herbaceous border has become most popular, it is not surprising that the hybridist has taken advantage of this, with the result that new varieties of various hardy plants have been raised which are far superior to the older kinds.

The phlox is one of these, and the following few varieties represent an advance on others raised, not only in the enormous trusses of bloom, but also in the very large individual flowers.

The first to be noted, Mauve Queen, which gained an award of merit, R.H.S., 1926, is a very distinct bright mauve, with a large white eye, and is of splendid habit.

Pretty Posy, colour cerise salmon, with carmine eye, has enormous pips and trusses which are very broad, giving the effect of a "posy." It flowers early in the season.

Nutfield Cheer, colour rosy mauve, with large white eye, has very large pips and fine habit.

Hilda is white, with carmine-rose eye, and fine broad truss of enormous pips.

Short and Sweet is a soft salmon, with carmine eye, the truss being rather pyramidal in shape, and the pips finely formed.—H. H.

Ferns for the Rock Garden.

NATURE delights in dotting flowers amid the ferns in many a shady and semi-shady nook, and the rock gardener may copy her example with great effect in a suitable corner of his rock garden. As a rule he will find that semi-shade at least is desirable; with that and a soil composed largely of fibrous loam, liberally enriched with well rotted leaf-mould, he is sure to succeed, but the general effect must never be overdone, nor the too rampant kinds grown in excessive profusion. Certain species are evergreens, a fact which adds considerably to their value, but even those which die down in winter do not leave the site wholly "dead" in effect. Common native species are best obtained from a fern nursery where they are cheap; foreign

Digitized by Google

hardy kinds may also be tried, though I do not consider them at all necessary for a small rockery; while the less hardy, like our native maidenhair, are well worth a little risk in attempts to bring them through each winter. As ferns cannot well be described, I merely give a list of names which the beginner can utilise in hunting up a catalogue, while the botanically inclined will recognise most, at least, as being common in our own country. First we have the polypodies, which in the refined forms of vulgare make delightful tufts; do not overlook here the beech fern, the alpine, the oak fern and the limestone polypody. In spleenworts (asplenium) there are the black maidenhair, the wall-rue, the scale fern and the black-stemmed. Filix-fœmina, the lady fern, offers a large choice of fine varieties; the hard fern, Blechnum spicant, is very good; the four or five species of cystopteris or bladder fern are all as good; the hart's tongue is ever a favourite and, when it grows well, is exceedingly attractive. Among foreigners one may select a few, not overlooking Lomaria alpina, Woodwardia cristata, one of the woodsias, and Adiantum pedatum. All should have a carefully selected and sheltered site.—H. F.

A Late Flowering St. John's Wort.

Hypericum Kalmianum.

THIS hypericum is especially valuable, flowering, as it does, when the majority of flowering shrubs are past. It commences opening its clear yellow flowers in July and continues for a period of a month or six weeks. As with most of the family, close spur pruning induces a more lavish display of flowers. It is in no way particular as regards soil, but enjoys an open position and an occasional watering when making its growth.—L. W. OLIVER, *Herts.*

[Our contributor gives the name of this hypericum as H. Kalmianum, but, according to Mr. Bean, this species is exceedingly rare in cultivation, and the plants under this name are generally H. prolificum. Both species are closely related and of similar habit, the main difference being that H. prolificum has a less handsome flower and a three-celled fruit, while H. Kalmianum true has a five-celled fruit.—ED.]

THE ALPINE VARIETY OF THE TREE HEATH, ERICA ARBOREA ALPINA.
A decorative shrubby heath for the rockery.

The Alpine Tree Heath.

Erica arborea alpina.

THE type of this attractive heath is a strong-growing plant, and will form a fine shaped bush 6ft. or 8ft. high, while it is also stated that it will make a tree with a well defined trunk and attain a height of 20ft. or more. Hence it is often referred to as the tree heath.

The plant illustrated is known as E. arborea alpina, a native of the mountains of Cuenca in Spain, and, if given a trim over with the shears after flowering, it can be kept within reasonable proportions, say, 3ft. or 4ft. high. During April it produces a mass of its nearly white flowers, which are very fragrant, and with age they assume a tinge of red. This species, owing to its beautiful green foliage, is a joy at all times, and especially in winter, when it is most conspicuous among deciduous trees or shrubs.

Signs are not wanting that heaths are becoming exceedingly popular, and when planting, the subject of this note should be included. It is ideal for "dot" specimens in close proximity to the dwarf kinds, while it is also valuable near the rock garden or in the shrubbery. Peat is not essential for many of the erica family, but most soils are improved by a liberal application of leaf-mould.—T. W. B.

A FINE AND LATE FLOWERING ST. JOHN'S WORT FOR THE SHRUBBY BORDER.
It is a shrub for the small garden, since it is one of moderate size.

Some Ornamental Fruiting Shrubs.

QUITE a number of trees and shrubs add to the brightness of the autumn garden by the brilliancy of their fruits. Practically all the crab apples are worth growing on this account. Those kinds which are especially effective are Pyrus prunifolia var. cerasifera, PP. Ringo, John Downie, Transcendent and Dartmouth. The Siberian crab, P. baccata, is also very effective when in fruit. Other kinds of pyrus which are worth growing include the white beam tree (P. Aria) with its several good varieties, all of which have fruits in varying shades of orange and scarlet; both the red and yellow fruited forms of the mountain ash (P. Aucuparia), and also the American mountain ash, P. americana. Among the thorns (cratægus) there are several very fine fruiting forms, such as CC. mollis, coccinea, punctata, orientalis, Crus-galli, cordata, etc. Most of the pyracanthas are also worth growing for the sake of their fruit. Another important family worth notice on account of its ornamental fruit is coton-easter. These shrubs will grow in almost any soil and are extremely easy to manage. Some of the best are included in the following list: C. frigida; C. rotundifolia, which grows to the height of 4ft. and retains its red fruits through the winter; C. Simonsi and C. horizontalis. Some kinds of roses are worth growing for the sake of their fruits. A charming fruiting evergreen is Pernettya mucronata. Other fruiting plants of interest include several of the barberries, Viburnum Opulus, spindle tree (Euonymus europæus) and Celastrus articulatus.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

THE weather conditions are deplorable. For three days and nights rain has fallen incessantly and hastened the end of autumn bloom in the open. Potato disease is spreading rapidly throughout the country, and in several of the principal producing districts the loss is estimated at 20 per cent. The trade are finding it difficult to procure seed, and it would not be surprising if retail prices are advanced in the coming season. Gardeners would therefore be well advised to lift any crop that still remains in the ground without delay and select sound tubers that may be required for seed. The sweet pea seed crop is also seriously affected, while at his lecture before the members of the Glasgow and West of Scotland Horticultural Society Mr. David Torrance predicted a heavy mortality among dahlias, as the abnormal moisture in the soil prevented the ripening of the tubers. The same thing may be said about roses, especially those of the rambler type, which send up long, sappy shoots which generally die back in winter when the new wood is not thoroughly ripened in autumn. The outlook is certainly depressing, but it is to be hoped that anticipations will prove to be worse than the realities.

The vegetable garden, which has produced good average crops in most districts, offers a more cheerful subject of discussion. In addition to the lifting and storing of beet, carrots and potatoes, referred to last week, there are several duties of a more or less routine character that require attention. Undeveloped fruits that remain on vegetable marrow plants will be the better for some protection in the form of a frame light or a little straw, and, unless the fruits are to be stored in winter, they should be cut while they are young and tender. In that case they should be allowed to get large and yellow, as they keep longer when pulled in that condition. Marrows require so much water that they are very susceptible to frost, and if there are indications of a low temperature at night, the prudent course to follow at this late season would be to gather all the fruits and take them indoors. Leeks and Brussels sprouts will benefit by an occasional application of liquid manure, and any spare space in a frame may be put to a good purpose by transferring a few plants of parsley from the open with the object of maintaining supplies in winter, when the outside stuff is not available. Plants may also be put in boxes or pots and a place found for them in the greenhouse.

Roses potted up in autumn as soon as maiden plants are available may be brought on and flowered under glass from March until May, when they may be removed to a sunny part of the garden to ripen their wood. Established plants can be forced into bloom earlier, but the amateur will find it more satisfactory to cultivate them in a moderate temperature of 45° or 50°, or even just sufficient to keep out frost. Under these conditions the plants come into bloom a little later, but the roses will be quite as good, if not better, than those produced in a warm atmosphere. A fine display is also possible to the owner of the unheated greenhouse who studies ventilation, and can take advantage of the increasing warmth of the sun in April and May by closing the ventilators about five o'clock in the afternoon. Use 7in. or 8in. pots, according to the size of the plant, and see that they are sufficiently crocked to ensure good drainage. Pot up the plants firmly in a compost consisting of two parts fibrous loam, one part well rotted manure and one part sand, with a little phosphate in the form of bone-meal added. After a thorough soaking place the pots in a cold frame and keep there until the end of January, when their removal to the greenhouse is advisable. While the plants are in the frame they must not suffer from lack of moisture, and plenty of air should be admitted during spells of fine weather. Many of the standard and newer varieties respond to culture under glass, but the beginner is recommended to make a selection from the following reliable sorts: Mme. Abel Chatenay, salmon pink; Mrs. Herbert Stephens, white; Ophelia, salmon flesh; Mme. Butterfly, blending of pink and apricot; Richmond, Courage and Hoosier Beauty, crimson; J. C. Mensing, rose pink; Sunburst and Roselandia, yellow.

When montbretia is undisturbed for a number of years the plants become crowded and the quality of the flowers deteriorate. To remedy this the corms or bulbs may be lifted and transplanted in October every second or third year, but some growers maintain that the best blooms are obtained by lifting the new shoots in spring when they are from 3ins. to 6ins. high and transplanting them in rich loamy soil in a sunny situation. Another alternative is to lift the corms in autumn and replant them in spring, a treatment that is not necessary from a weather standpoint, as montbretia is quite hardy. If the specimen grown in the garden belongs to the old smaller-flowered type, the amateur will obtain more satisfaction by discarding it in favour of the new and improved introductions that are richer in colour and larger in the size of the individual blooms.

Grass that is showing indications of tear and wear may be restored by a little treatment in the form of top-dressing in October. Impoverishment and neglect are responsible for most of the defects that are to be seen in lawns and greens, but if the troubles are not of long standing they are easily remedied. Used as a winter dressing basic slag possesses beneficial properties, and if the greens have only to be maintained in a satisfactory state all that they require is a little nourishment twice a year in the form of phosphate in winter and sulphate of ammonia in April. The presence of moss usually reflects a sour, wet soil, and after scarifying the patches with an iron tooth-rake a light surface dressing of lime should be applied a month or two before seed sowing. ST. MUNGO.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful and interesting hint sent in by a reader. Five shillings will be paid for all others published. Payments for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Wasps in Greenhouses.

It may not be generally known that wasps have a great liking for pitcher plants. Where they are troublesome in a greenhouse, particularly in houses devoted to vines or other fruits, a pitcher plant will trap every one. These plants are easy to grow in any greenhouse. They are most serviceable when grown in a pot that is suspended from the roof by a wire.—R. H.

How to Use All Your Outdoor Tomatoes.

Tomato growers have to be very careful at this time of year to save their crops from the first severe frost. The best time to pick the green tomatoes is usually from October 1st to 15th, but in a favourable season some may be left up to the end of October without harm.

Separate out those that are likely to ripen and put them in flannel in cardboard boxes (tennis-ball boxes are useful), then place the boxes in a warm cupboard in the kitchen, look at them every four days, and you will be surprised to see how many of them ripen.

The other batch, that are smaller and too green to ripen, can be used to make a most excellent green tomato chutney, as follows: 3½lb. each tomatoes, apples and Demerara sugar, 1lb. shallots, 3½pints vinegar, 3½oz. preserved ginger, 18 red chillies, ¾lb. sultanas, 2 tablespoonfuls salt. Boil vinegar and sugar in preserving pan, slice tomatoes and apples into this syrup (apples are weighed after peeling, coring and quartering them). Add other ingredients. Boil all well, stirring all the time, until mixture thickens and sets firm when dropped on a plate. Pour into hot jars, and cover when cool. Keep in a cool place.—E. W.

Conveyance of Leaves, etc.

Nearly every gardener has, at some time, a large quantity of leaves or clippings from hedges and shrubs to move. This is more often than not done by means of a wheelbarrow, buckets, etc.; but the ground is not always in a condition to use the former, and with the latter only small quantities can be moved at a time, and then bits drop *en route*. The most satisfactory and quickest method I have found is to obtain a piece of sacking 4ft. or 5ft. square; place it flat on the ground and pile the leaves, etc., on it, then bring each corner to the centre, and carry the whole to where it is required.

How to Waterproof Garden Nets.

Garden and tennis nets may be given a considerably longer lease of life than they usually have if they are waterproofed. This is how waterproofing should be done: Dip the nets in boiled linseed oil, then roll them up for about fifteen minutes. Then hang them up to dry. When they are dry repeat the process. Go through the same process again with this mixture: 7 parts of boiled linseed oil to 1 part of copal varnish. When not in use, store in a dry, cool place.—C. W.

Apple Rings from Windfalls for Winter Use.

Peel and core any windfall apples you may have and cut out all bruised spots. Next cut the apples into thin rounds. Put some rows of string across the inside of your airing cupboard door and thread the apple rings on to them. Leave them there for a few days until hard and dry. They will keep all the winter in a bag or jar and be found very useful for sauces, curry, etc. Keep in a dry place and, if necessary, soak in water before using.—K. W.

Bulbs Plunged in Ashes.

Readers who grow bulbs in pots of soil will be familiar with the annoyance caused by the ashes—in which the pots are plunged—sticking to the surface of the soil. To obviate this nuisance, the pots of compost should be given a fairly thick surface coating of sand. Ashes will be found to come off this cleanly and, in any case, the sand can be cleaned off quite easily.—D. S.

PLANTING HARDY SHRUBS

Helpful Hints which will Ensure Success.

THE increasing interest taken in gardening as a hobby, and particularly outdoor gardening, during the last few years has resulted, among other things, in more attention being given to the preparation of the ground, and the planting of better selections of hardy shrubs. There is, however, still room for improvement, both in the preparation of the ground and the choice of interesting and showy flowering and ornamental foliage shrubs.

With regard to the preparation of the ground, the first thing to remember is that once planted in their permanent positions it is not intended to disturb the majority for some years. Thus, the future welfare of the shrubs may be said to a great extent to depend on the preparation of the soil previous to planting. If a border of shrubs is to be planted, trench the whole of the ground 2ft. deep, adding manure, also soil suitable to the plants, should the ground be very poor. Failing well rotted manure, there is a refuse heap in most gardens where vegetable rubbish is deposited — grass clippings, old flowers, weeds, leaves, etc.

In preparing stations for single or specimen shrubs, dig out circular holes 4ft. to 6ft. in diameter and 2ft. deep, according to the size of the shrubs. Prepare and manure the soil as for the borders.

The Time of Planting

is important. Evergreens as a rule are best moved in late September or during October while the ground is still warm and the temperature sufficiently high to encourage the making of fresh roots in the new positions without delay. This is important with evergreens, for throughout the year transpiration of the leaves is continuous. Failure of the roots to maintain sufficient moisture through loss of roots and general disturbance in transplanting may mean the weakening of a plant and the loss of leaves; or, if very badly hit, especially in cold weather, it may result in the death of the plant. When the autumn planting of evergreen is not convenient, defer the work until April.

A very good practice—one may even cite it as a necessary operation—is to shorten and thin the crowded growths of evergreens when transplanting, to balance matters, as it were, because of the loss and disturbance at the roots. In bad cases, when comparatively few roots are moved in proportion to the size of the shrubs, it is worth while reducing the tops by half. Far better to do this than be almost certain to lose the plant.

When planting shrubs always dig out a hole of sufficient depth to accommodate the roots. The top layer of turf, which is removed and which can be seen on the left of the illustration, should be placed grass downwards at the bottom of the hole and the finer soil on top.

With most deciduous shrubs, transplanting is easier, and pruning when planting not so vital; but even so the shortening of long shoots is often desirable. While early planting is desirable and November advised, as soon as the leaves turn yellow and fall there is not the great need for hurry, as there are no leaves on the plants requiring nourishment immediately planting is done. Thus, the planting of deciduous shrubs may continue through the winter, when weather and soil conditions permit.

The Depth to Plant

or to cover the roots is more important than generally understood. Taking a leaf out of Nature's book, we find the buttress roots of the trees in the woods protruding well above the ground, and in moving the loose surface soil we find plenty of feeding roots near the top. Here is positive proof that shallow planting is desirable in order that the feeding roots may be near the surface and so have plenty of air and the sweetest soil to grow in.

It is worth while laying a stake across the top of the hole, as illustrated, so that the depth the roots will be covered when the hole is filled in can be readily seen.

When preparing a piece of grass or meadow-land for planting, do not, as is so often done, strip off the turf and cart it away. This is the kind of soil the professional gardener describes as top-spit loam, so much in demand, after six months' storing, for potting greenhouse plants. It is also very valuable material for trees and shrubs, roses and herbaceous plants. When preparing holes for planting, as illustrated, place the chopped-up turf in the bottom, covering it with a little fine soil, before placing the shrub in position. In six months time, when decayed, it will be splendid rich soil for the young feeding roots.

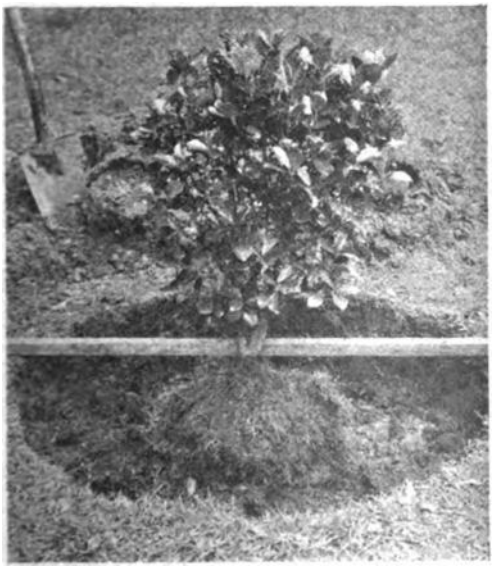
As the holes are filled in with soil, tread firmly without damaging the fibrous roots. To facilitate the watering of specimen shrubs, form a basin by making a circular ridge of soil round the bush to ensure the water soaking in through the roots.

Choose, if possible, showery weather for planting evergreen shrubs, or, at least, avoid planting when it is windy and cold. Even if it rains after planting evergreen shrubs, it is better to give a good soaking with water.

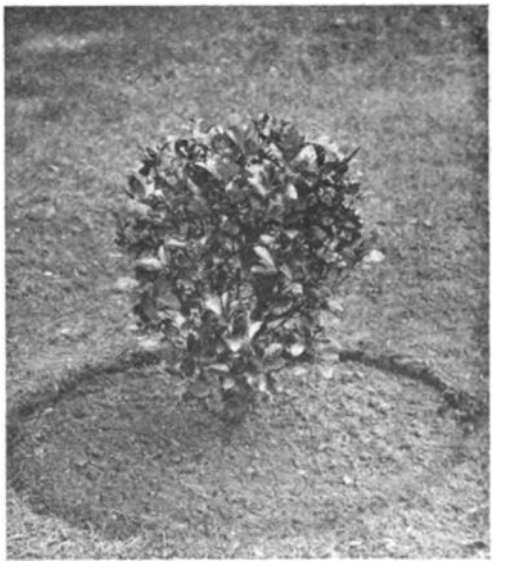
Shrubs of any appreciable size likely to be swayed by wind during the winter should be firmly supported with stakes. Swaying and loosening at the roots or ground level may soon do irreparable damage to choice shrubs.

The evils of deep planting are not usually apparent for a number of years. The decline in health may not show itself for several years, then a gradual failing is apparent. What really happens is that the stem, being buried and in contact with damp soil, the bark and then the cambium layer of many shrubs and trees gradually rot until the channel through which the food supply is carried from the roots to the stem branches and leaves entirely rots away. The trouble of deep planting occurs with both trees and shrubs, though some have the ability to develop roots on the stems and so avoid decay. Rhododendrons are among the first to suffer from deep planting; also lilacs, birch and thorns (cratægus); so will evergreen and deciduous oaks, most conifers and lime trees. Elms, poplars, willows, tamarix and forsythias may be cited as examples of trees and shrubs which seem indifferent to the deep burying of the stems.

A. O.



The shrub placed in position with the collar of the plant placed at the soil level and the roots spread out.



Planting completed. Note that the bed is slightly raised. Evergreen shrubs should be watered after planting.

THE FRUIT AND KITCHEN GARDEN

Grease-Banding Fruit Trees.

An Operation to be Done Now.

THIS grease-banding is carried out as a control measure for the winter moth, March moth and mottled umber moth, the larvæ of which are capable of doing an enormous amount of damage in the spring by eating buds, leaves, flowers and young fruit of the attacked trees and spinning the leaves and blossoms together and living beneath their protection until May or June, when they descend to the ground.

The life histories of these three pests are all similar. The eggs are deposited on the branches of trees, the larvæ hatch out in the spring, feed, and then pupate in the ground. From October to December or January the moths emerge from the chrysalides in the ground. The female moth—which is wingless, and thus *incapable of flight*—crawls up the trunk of the tree and deposits her eggs, which eventually hatch into a new generation of voracious caterpillars.

The grease-band is effective in that it entraps the female moths in their journey up the trunk; but to be successful it is essential that it be put in position before any moths have ascended the trunk, and for this reason the middle of October is quite late enough to have all grease-banding completed.

Any of the well known makes of proprietory "grease" will be found effective, and the directions for use issued with them will be found quite simple to follow.

The paper band, which should be from 7ins. to 9ins. wide and made of good, stout greaseproof paper, should be securely fastened around the trunk of the tree at a distance of from 3ft. to 5ft. from the ground, with two pieces of string tied tightly about 1in. from either edge of the paper.

Apply the composition to the 5ins. or 6ins. of the centre of the band, taking care that none is smeared on the bare trunk of the tree, for this is detrimental.

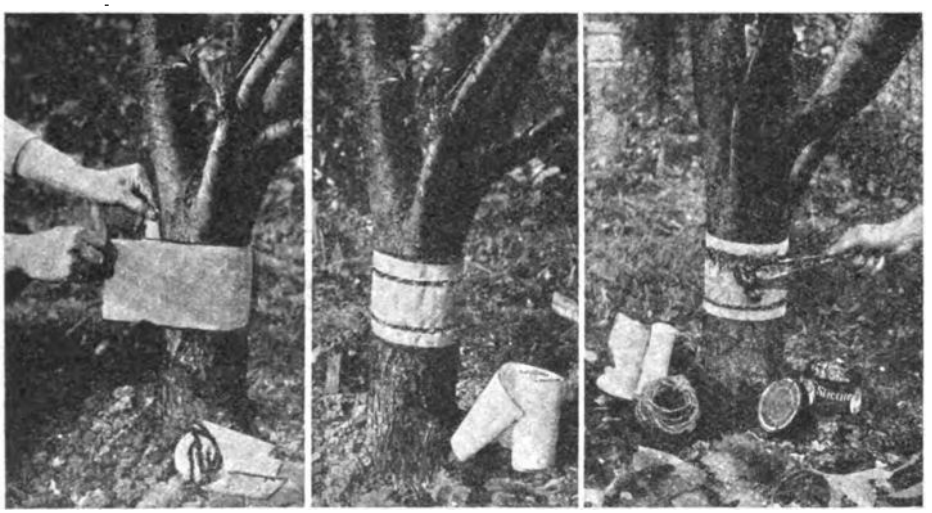
As a general rule, the simplest way to apply the grease to the band is with the hand; but if this method is objected to, shaped pieces of wood may be used instead.

A good composition will remain in a "tacky" condition for several months, but it is advisable to examine the bands at intervals throughout the winter and scrape the surface away occasionally to expose a fresh surface to the air.

Grease-banding is not practicable on bush trees which branch close to the ground, as the bands become a trap for dead leaves, small sticks, etc., which form bridges over which the moths crawl; but all standards, half-standards and bushes with a clear stem 16ins. long or more should be banded at all costs. Attacked trees which are not grease-banded must be treated by spraying with lead arsenate or some other approved stomach poison in the spring. In cases where trees are attached to stakes it is necessary, of course, to band the stakes as well as the trees.

Even with autumnal banding a few caterpillars may be expected to appear in the spring, as it is now quite certain that a few female moths are almost invariably carried to the branches by the winged males; thus, a spring spraying is always a wise precaution.

Apples, pears, plums and cherries are all liable to serious attacks and should, therefore, all be afforded the protection given by a grease-band.—T. H. E.



Place the band of grease-proof paper in position. *Tie the band securely top and bottom with string.* *Apply the sticky substance with an old knife or piece of wood.*

Earliest Cauliflowers and Peas.

AUTUMN-RAISED cauliflowers and peas are, as a rule, much earlier than plants which may be raised in any other fashion, and the present week is a suitable time to ensure that full supplies will be available. Although it is not too late to sow cauliflower seed (in a frame) most will have seen to this already; now fill up a frame with good friable compost and plant the seedlings 3ins. apart therein, making them firm. Water the plants in and keep the sash close for a week. After that give the plants full ventilation on the good days by throwing off the sash entirely, but only give a little air on bad days; keep the sash tight in hard frost and in foggy, muggy weather. As a matter of fact, the cauliflower plants must be treated as almost hardy and not coddled in any way. Such plants, hardened off in February, may be planted out in March or April according to season and district. A few plants potted up in small pots and planted out intact are earlier still, while readers with cloches may plant in twos in the open and keep them there all winter. In a somewhat similar fashion can peas be grown. Sow the seed just now in small pots, say eight in a 5in. pot, using a free compost of loam, mould and sand. Germinate in the frame or under sheets of glass and winter the plants in the frame. In cases where frame space is limited, they may stand at the foot of a wall, provided that glass is sloped over them in bad weather. The plants in clumps with the ball of soil intact are planted out 18ins. apart at the end of February in trenches similar to those made for growing sweet peas.—H. H. A.

Autumn-Sown Broad Beans.

GARDENERS who advocate the sowing of broad beans in the autumn should never neglect to point out that such sowings are a gamble with Nature. Very often they come along all right and yield surprisingly early crops; again, we may have short "growing" spells of weather during winter and then a few days of bitter frost which simply ruin the plants temporarily and retard them so much that they only just manage to keep pace with the earlier-sown spring stuff. Still, I consider an autumn sowing advisable. Sow the seeds as usual at once, covering them with 2ins. of soil beaten firm, without manure underneath. Should the soil be heavy and retentive, however, the best plan is to lay the seeds on the level and earth soil up over them, because the shallow trench alongside keeps sufficient drainage to help growth. In spring scatter a mulch of manure alongside and a few weeks later hoe this up round them and cover it with soil.—K.

Kales for the Kitchen.

A CENTURY ago early kale was the main winter green vegetable, but the modern cook has little use for it and it is seldom grown. Even in Scotland the "extra curled" is passing out of favour, and those who do grow plants often prefer the Asparagus type, which sprout so freely in spring and yield large pickings of nice tender shoots. Sprouting kale is not so much curled, but it produces shoots in plenty and these cook to a delicious dish. All these kales come into condition after a frost or two, generally from the New Year onwards, and they are extremely hardy. The Drumhead kale serves a double purpose; the heart grows moderately compactly and is cooked like a savoy, while the leaves, if properly cooked, are very fine. Unfortunately the kales have all come to be considered coarse vegetables. Perhaps the judges are coming to a decision from appearance alone, because every true kale-bred Scot can vouch for the fact that a good cook can make kale fit for any table. By the way, the Perfecta strains of variegated kales have done exceedingly well this year.—C.

Final Earthing-Up of Celery.

THE celery crop has made nearly all the growth possible this year, and it should now be earthed to blanch the leaf stalks. Tie together first and then just place soil round the stems, leaving the green tops peeping out from the top of the ridge. A dusting of soot and lime applied before earthing up is advisable to keep away slugs. It will take three or four weeks to blanch the stalks.

Lifting and Storing Onions.

ALL onions are now ripe enough to lift and store. Pull them up on a sunny day, allow them to remain a few hours to dry and then rope them together. Hang them in a dry, airy shed until used. Thick-necked onions should have their tops bent over and then be left for several days before lifting, so that they can ripen. Small pickling onions should be gathered and stored away from the wet.

A GREAT AUTUMN SHOW

THE Holland Park Show, the annual autumn exhibition of the Royal Horticultural Society, which was held at Holland Park Hall on Wednesday, Thursday and Friday last, September 28th, 29th and 30th, has come to be looked upon as a floral event in the gardener's calendar quite as important as Chelsea. In many respects it is even more so, on account of the time of year when it is held. At this season visitors to the Show can place orders that can be despatched, if the weather is suitable, almost at once, while, in addition, at the end of the gardening season the gardener is better able to make up his mind as to what is required particularly for next year. In this frame of mind the visitor will find Holland Park a source of interest combined with instruction, and it is an event that all amateurs should endeavour to attend if possible. An autumn show, such as Holland Park, will assist one in deciding on how to stock the garden for next year.

This year, despite one of the worst of gardening seasons, the display was a particularly fine one, and the fears that had been entertained regarding the flowering display happily proved groundless. The exhibitors at these shows seem to have a happy knack of surmounting difficulties of weather, and they deserve congratulation for the attractive groups which were staged. Holland Park is a representative show. Flowers, trees and shrubs, fruit and vegetables are all shown in variety, and this year there was a happy balance between the sections. Dahlias were much in evidence, and their glowing shades of colour did much to add to the attraction of the Show from an appearance standpoint. Michaelmas daisies were also a feature on many stands.

SHRUBS.

The shrub groups on this occasion were outstanding in quality and variety. One has come to associate autumn with berry and tint in the world of shrubs and trees, and while these were present there were many examples of autumn-flowering shrubs, indicating the wide scope of shrubs for decorative effect in the garden.

Messrs. Hilliers of Winchester, as is their custom at this show, staged a group which was attractive as well as interesting. The lover of rare shrubs will always find something of interest on their stand. This year's display included many species of berberis all hanging in fruit. Among them we noted B. concinna and a new one, B. Gilgiana, which seems allied to B. brachypoda. Cotoneasters were also present in variety, while many species of cratægus and pyrus contributed to the colour display of fruit. Two pyrus species which were outstanding were the decorative P. Malus Sargentii with its clusters of crimson fruits and the yellow-fruited Cashmere crab. The uncommon flannel buddleia, B. Farreri with its thick woolly leaves, pure white underneath, was also on view, while Desfontainea spinosa were notable for its wealth of flowers. The brilliant red hips of Rosa Moyesii were a feature, and also the autumn tints of the maples and the two rhus species, R. typhina and cotinoides. Acer Hersii, a new maple from China, shown for the first time last year, was also on view.

Conifers in variety were a feature of the fine exhibit staged by Messrs. Waterer, Sons and Crisp. They were admirably arranged and interspersed with fruiting barberries, cotoneasters and the bright tints of ornamental vines. Among the barberries we noted a new variety that is being put on the market this autumn. It is known as Berberis Unique, and appears from its habit and shape to be closely related to B. concinna and B. Thunbergii. No matter its parentage, it is a fine barberry, decorative in fruit and foliage, and one certainly worthy of a place in the garden. An interesting and rare conifer was present in Juniperus sinensis var. Meyer. It is one of the bluest green junipers and a most attractive shrub for the rock garden. There were numerous other subjects all shown in first-class condition, many of them suitable for adding beauty to the shrubbery in even a small garden.

Messrs. Cheals of Crawley staged a most attractive exhibit. It was bright and varied in its appearance, largely on account of the introduction of many autumn-flowering shrubs. Among the late-flowering shrubs were Ceanothus Gloire de Versailles, the Mexican orange, Choisya ternata, Clematis Flammula, Escallonia floribunda, Hydrangea paniculata grandiflora with its decorative white flower trusses, buddleias and the fine Veronica Autumn Glory. Added to these were a selection of shrubs in fruit with fruiting crabs and variegated and autumn tints. The pernettya and the symphoricarpus were well berried and made an attractive edging round the exhibit. It was an instructive group, since it showed the wide variety of purposes for which shrubs may be used in the garden provided the proper kinds are selected. It is from such a group that the amateur may learn a considerable amount regarding the variety to be obtained among modern shrubs and trees.

Another well arranged group was that staged by Mr. R. C. Notcutt. This exhibit included the brilliantly coloured Euonymus alatus; the free-flowering Potentilla fruticosa var. Farreri, a delightful shrubby plant smothered in yellow blossoms and one that should be far more often grown not only in the shrubbery but in the herbaceous border; berberis sp. in fruit; Cotoneaster Vicarii in berry; Stranvæsia Davidiana with clusters of scarlet fruits; and several subjects in full flower, among which were ceanothus, Escallonia C. F. Ball, Choisya ternata, Viburnum fragrans and Buddleia Fallowiana with its attractive white woolly leaves.

The decorative foliage of the large-leaved rhododendrons formed the main feature of the exhibit of Mr. G. Reuthe. It was an interesting exhibit, although perhaps a trifle dull in appearance. Flowering sprays of numerous shrubs were shown, while a number of berried cotoneasters and barberries were also present, along with conifers.

Messrs. Wallace exhibited shrubs and conifers with lilies and clematis, and the arrangement was good. Berried shrubs, such as Skimmia japonica, berberis, Rosa Moyesii, cotoneasters, cratægus and others were attractive, while the autumn-tinted Japanese maples were particularly fine.

Messrs. Russells of Richmond had a fine display of their notable varieties of clematis, which were in excellent condition. Both the lanuginosa and Jackmannii sections were well represented with such varieties as the new Crimson King, Marcel Moser and ever-popular Nelly Moser, the dark-toned Gipsy Queen, Comtesse de Bouchaud and the violet-blue Jackmanni itself.

The other chief exhibitors of shrubs were Hollambys Nurseries (a fine group with many species of ornamental vines), Messrs. Charlton and Sons (berried shrubs in variety), Messrs. Fletcher Brothers (berried shrubs), Mr. Geo. G. Whitelegg (rock garden conifers), Messrs. Klinkhert (topiary work) and Messrs. Robt. Green and Co. (standard bay trees).

MESSRS. DOBBIES' CENTREPIECE EXHIBIT OF DAHLIAS.
All types and many excellent varieties were displayed.

DAHLIAS.

In spite of the recent bad weather, numerous firms were able to stage some excellent displays of dahlias. This year there were fewer single and miniature peony-flowered varieties to be seen, but large decorative and cactus dahlias were shown in great numbers, and all were in good form. Some of the newer soft pink and rose decorative dahlias are particularly attractive, and among these Jersey Beauty was outstanding. Many firms exhibited this novelty; both Mr. H. J. Jones and the King's Acre Nursery had a magnificent pillar of it. Macdonald, an orange scarlet decorative dahlia; Canary, an incurved cactus variety; and Rover, of the same type as the latter, were also popular varieties. One of the most striking dahlia exhibits was staged by Messrs. Dobbie and Co. Dahlias of every class were included in this stand. Peter Pan, Paisley Gem, two of the best Coltness Gem type; Joan Fife, a tangerine peony-flowered dahlia; Joyce Healy, a decorative variety of uncommon colouring; and The Prince, a large crimson scarlet decorative, dahlia, were all in good condition; in fact, every one of Messrs. Dobbie's dahlias had stiff rigid stems, for they had been grown naturally, and not disbudded to produce over-sized flowers. The visitor saw the flowers as they can be grown in the garden.

Digitized by Google

Messrs. W. Treseder staged their dahlia exhibit particularly well, and their cactus and decorative varieties were most effective. Some of the finest of decorative varieties were President Wilson, Portia and Emblem ; while the salmon pink Edgar Jackson, the pink and yellow Emblem, and J. Emberson, all cactus varieties, were noted.

Messrs. J. Cheal and Sons showed many dahlias of their own raising, including some of their famous star dahlias, such as Horsham Star and Woodhurst Star, which are so useful for filling gaps in the herbaceous border. A large crimson decorative dahlia—Mrs. D. Hepburn—on this stand attracted much attention. Mr. H. J. Jones had good blooms of Reginald Godfrey, one of the best crimson decorative dahlias, and Princess Louise, a pretty pink variety of the same class, among his collection of fine dahlias. Another large group was staged by Messrs. J. Stredwick. The varieties Nora Philips, A. J. Cobb, Hyde Park Beauty, Mrs. S. Sandeman and Buccaneer were included on this stand. Some of the most effective varieties shown by Mr. C. Turner were A. E. Amos, Dr. Spath, Nora Purple, The Prince and Romney as their best varieties ; Messrs. D. Prior, Messrs. Jarman, Messrs. J. T. West, Messrs. T. Riding, Messrs. John Forbes and Mr. H. Clarke. The latter exhibitor showed many pretty pompon dahlias ; while on Messrs. Jarman's stand were seen many of the finest of modern varieties.

GLADIOLI.

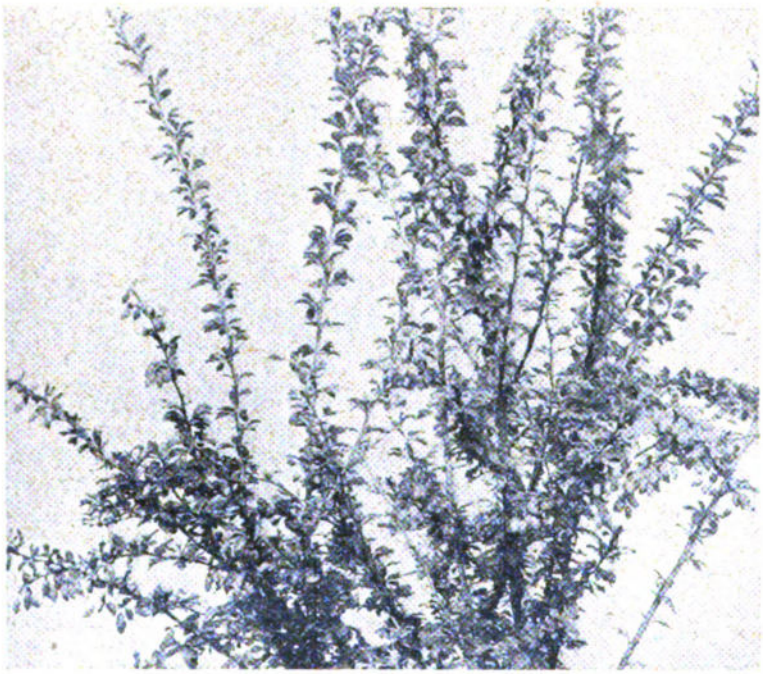
It is late in the season for gladioli, but notwithstanding that and the bad weather experienced prior to the Show, Messrs. Austin and McAslan of Glasgow staged a very fine display of large-flowered and primulinus varieties. The spikes of bloom were in excellent condition, and the growers deserve every congratulation for their exhibit. Among the varieties we noted the scarlet Fairy King, the murky Baron Hulot, Pink Perfection, the yellow Souvenir and several dainty primulinus, including Salmonea, Golden Drop, Atalanta and Daphne. The group was well arranged and the individual varieties could be seen to perfection.

Messrs. Allwood displayed border carnations, Sussex Crimson, Sussex Rosalind and Sussex Beauty. Allwoodii carnations, including Sylvia, salmon ; Pat, double deep salmon red ; Esther, semi-double white, splashed red ; and Betty, white with carmine centre, single. Their perpetual flowering carnations included the fine varieties, Harmony, mauve ; Velvet ; Maine Sunshine, yellow ; White Pearl ; Laddie ; Master M. Stoop, cerise ; and Eldora, a white, flaked with red, were among others shown.

Messrs. Engelmann showed Snow White and Blanche ; Topsy, crimson ; Janet, good cerise ; Master Michael Stoop, cerise ; Katja, mauve ; Rouge, a red self ; Mrs. Hamilton Fellowes, cherry ; Jazz, yellow ground, flaked red ; Nero, white ground, splashed red ; and Laddie, with its sport, Red Laddie. Coral Glow was also shown.

CHRYSANTHEMUMS.

Messrs. William Yandell's display included Harvester, yellow ; Crimson Circle, deep Red Almirante ; Sanctity, white ; Septembe Glory, soft yellow ; Bronze Buttercup



THE NEW BERBERIS UNIQUE, SHOWN BY MESSRS. WATERERS. THE BRANCHES BEAR BRIGHT RED BERRIES.

A WELL FRUITED COTONEASTER, C. DIVARICATA, EXHIBITED BY MESSRS. HILLIERS.

Bell, Radium and Gatton Star. Messrs. W. Cutbush brought some good dahlias, including the pure yellow Clothilde, the orange scarlet Macdonald, King Harold (dark mahogany), Maria Houtman (a beautiful golden orange decorative variety) and the attractive old gold decorative La France. Dahlias of uncommon colouring were shown by Mr. R. Winder. Mme. J. van Jost was a mauve shaded with pink ; and Roi de Jaunes a striking variety of sulphur yellow. Mrs. Skevington, a peony-flowered dahlia of perfect form, was noted on the stand of Mr. Henry Woolman, who also showed Mabel Lawrence, a crimson scarlet decorative dahlia of enormous size, together with the light bronze Mrs. Murray, and the dark red cactus variety Harry Strutt.

Messrs. Dickson and Robinson had a well staged and representative collection. Northern Gem, a new dwarf bedding dahlia ; Pink Pearl, a miniature decorative variety ; Insulinde, Edgar S. Jackson and Pride of California were also exhibited.

Numerous other firms staged dahlia groups, including Messrs. Carter Page, with Royal

Messrs. Baths of Wisbech also staged a group of primulinus varieties, but the spikes had suffered from weather and were a little past their best, showing a lack of that richness in colour which characterised this firm's exhibits at earlier shows. All the leading primulinus varieties were shown. The presence of gladioli at a show in late September indicates how valuable this flower is when it commences to flower at the end of June and lasts until now.

Messrs. Orpington Nurseries had a comprehensive exhibit embracing many of the leading varieties of both the large flowered and primulinus sections, all in fine condition. Some of the spikes were of good colour and particularly noteworthy in this bad season.

CARNATIONS.

Messrs. Stuart Low showed a new salmon seedling, unnamed ; Happidans, deep apricot; Melcher Beauty and Queen Mary, very dark crimson, three novelties for 1928. Daphne, new 1927, also Topsy, crimson self ; Lady Hindlip, pink flaked with red ; Fragrant Rose, Eileen Low and Ruby Glow.

incurved ; Golden Almirante ; Phil Page light bronze and Minstrel, dark red.

Messrs. J. W. Forsyth showed early chrysanthemums cut from outside. Hollicot, yellow, was particularly good ; September White, Shirley Bronze, Phœnix, Mrs. Jack Pearson, light bronze, and Salmon Profusion, were also shown.

Messrs. Woolmans exhibited Rodeo, a yellow bronze, and Jack Robbins, bronze, and the Japanese variety, Red Ensign.

Messrs. Wilson and Agar displayed September Glory, bronze ; September White ; September Yellow, as disbudded blooms, and Rio des Blancs, Phœnix and Goldfinder as sprays.

Messrs. Keith Luxford showed a new seedling, semi-double, with open centre and rosy pink petals. Perle Chattillonaise was good, as was Cranford Cream. Other varieties shown included Phœnix, bronze spray ; Framfield Early, white ; Pink Delight ; Bronze Cranfordia and Elsenham White.

A mixed display of Messrs. Bunyard's contained the Chrysanthemum J. McAlpine ; The King's Acre Nursery, Berengaria, a

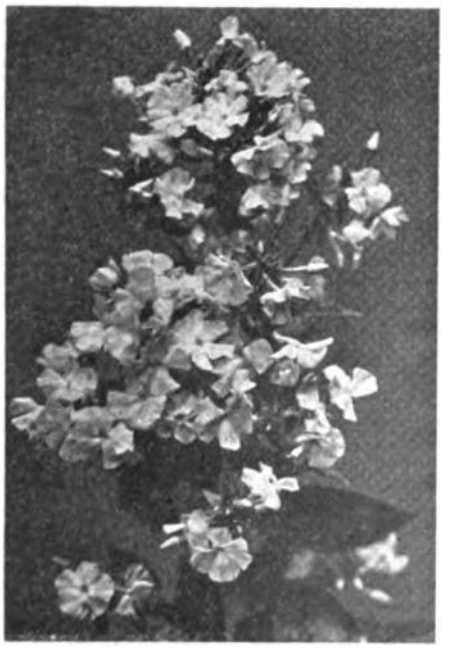
1926 introduction; Mrs. Phil Page, 1926; Martin Reed, a fine yellow; Mme. Marie Masse, pink; Golden Firebrand, single yellow; Horace Martin and La Pactole.

Lowe's White, September Glory and Mrs. Jack Pearson, bronze, were staged by Messrs. Callick.

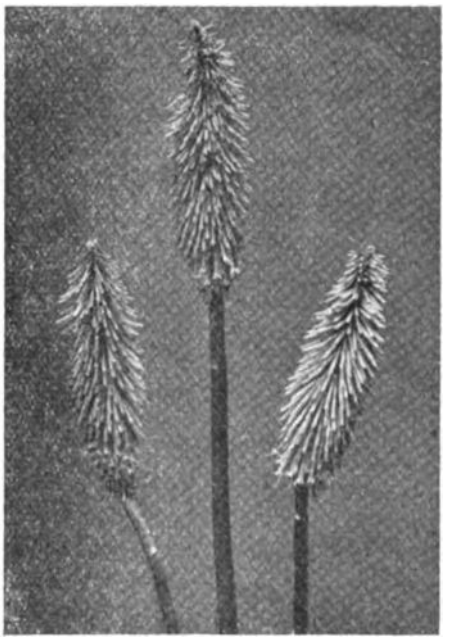
MICHAELMAS DAISIES.

Perennial asters are always one of the features of this great autumn show. One always expects good displays of these useful border plants from such aster specialists as Mr. E. Ballard, Messrs. W. Wells, Messrs. Barr and Sons, Mr. T. Bones and Mr. H. J. Jones, and this year their exhibits exceeded expectations, although weather conditions have been far from favourable. In some cases the collections were not so representative as in previous years, for in many districts the varieties are not yet fully out. A number of growers found that Barr's Pink was not sufficiently advanced to cut, and that Blue Gem, Dick Ballard and others were still in bud. Barr's Pink, King George, Royal Blue, Little Boy Blue and Margaret Ballard were, however, to be seen on nearly every stand and undoubtedly these varieties can be classed as some of the finest of modern asters. Messrs. W. Wells, who staged a very effective exhibit of well grown asters, had columns of all these varieties, as well as excellent sprays of Rachael Ballard, Snowdrift, the pretty rose pink aster Maid of Athens and Mrs. George Monro, a large white Michaelmas daisy. Messrs. Barr and Sons made a prominent display of Barr's Pink, the best of the Amellus section. Mr. Ernest Ballard again showed Ruby Tips, one of his novelties of last year. He also staged many others of his recent introductions, including Countess (a rose-coloured aster), Empress of Colwall (an outstanding variety), Wonder of Colwall, October Dawn and the charming dwarf variety Little Boy Blue. Two good novelties were shown by Mr. T. Bones—one, Sonia, a single rosy mauve variety with large flowers, the other Hope, a rosy purple. Ultramarine, a good variety of the Amellus section, together with Aldenham Pink, Margaret Ballard, Miss Eisle, all of the Novi-Belgii section, were conspicuous.



THE NEW DEEP PURPLE BLUE PHLOX, TRIUMPH. SHOWN BY MESSRS. FAIRBAIRN.

A large display of asters of all shades was put up by Mr. H. J. Jones, who introduced with good effect several groups of Helianthus Monarch, one of the finest of the sunflowers. The Michaelmas daisies Blue Gem, Little Boy Blue, Maid of Athens and Anita Ballard were also noted on this stand, and Pink Pyramid was much admired. Messrs. Cutbush had some good asters among their collection. Royal Blue was one, Thora Perry, pale lavender, a dwarf variety, another, and Wienholtzi yet another. Messrs. G. Whitelegg had some of the best of the amellus section, including Beauty of Ronsdorf, which has large, mauve pink blooms. Messrs. W. Wood staged a very fine Michaelmas daisy exhibit which contained many good varieties of the Novi-Belgii section and good blooms of Barr's Pink. All their asters were well grown and in good condition. Helianthus sparsifolius, a bright yellow, large flowered, was conspicuous on this stand. Grey Lady, Walkden's Pink, Duchess, Maggie Perry and many others



A GOOD SCARLET RED-HOT POKER (KNIPHOFIA H. G. MILLS). SHOWN BY MESSRS. BAKERS.

were displayed by Messrs. W. Sydenham, Mr. T. Carlile, Messrs. Bunyard, Messrs. Skelton and Kirby, the Chalk Hill Nurseries and many other firms exhibited Michaelmas daisies together with other hardy border flowers.

All these newer Michaelmas daisies are great improvements on the old varieties, and as they are easy to grow some of them should be planted this autumn.

HARDY BORDER PLANTS.

Great interest was taken in the exhibits of herbaceous perennials, for it is at this time when the work of making and renovation of borders is at hand that all gardeners are on the look-out for new plants to include in their planting schemes. Many fine autumn-blooming perennials were on show, as well as a number of new phloxes and kniphofias and some striking new hardy lobelias.

An interesting collection of hardy plants was staged by Messrs. M. Prichard. Asters, phloxes, pyrethrums, were there in plenty. Helianthus Rev. Wolley Dodd, a clear bright yellow; the snakeroot, Cimicifuga simplex, with its feathery white flowers; Poterium

A NEW MAUVE PINK MICHAELMAS DAISY, SONIA. SHOWN BY MR. T. BONES.

obtusum, with flower spikes of rosy mauve; Rudbeckia The Pilot, a handsome cone flower; and Cynoglossum amabile, the Chinese hound's-tongue, which were exhibited by this firm, are perennials which should be more often grown.

Messrs. Baker staged an effective group, which was backed by a bank of Michaelmas daisies in varying shades of blue and mauve. A particularly good kniphofia was noted on this stand. Its name is H. G. Mills, and, besides being a tall grower, its spikes are of bright flame scarlet and are not shaded with yellow, as is the case with the majority of kniphofias. Phloxes, delphiniums and sidalceas were also exhibited.

Some new herbaceous phloxes shown by Mr. R. Fairbairn attracted considerable attention owing to their unique colouring. Triumph, a rich blue variety, was one of the most recent novelties; other striking varieties were The King, clear purplish blue; Attraction, soft salmon pink; Lord French, carmine; and Border Gem, one of the bluest of phloxes. Mr. Amos Perry had some fine pentstemons, one named White Bedder, and another Chester Scarlet, among his collection of border plants. Good sprays of Helenium autumnale rubrum and Riverton Gem, and the purple-flowered spikes of Liatris pycnostachya, made bright splashes of colour on this stand.

A mixed collection of border plants was put up by Messrs. Harkness; Lupins Queen of Hearts and Pink Progression, Verbascum C. L. Adams, Montbretia Prince of Orange, Delphinium Lizzie Anderson were included. Harkness' Regal lupins are becoming widely known. Mr. R. C. Case showed Coreopsis auriculata superba, One of the most useful of yellow-flowered perennials for the amateur's garden. This easily grown perennial produces its flowers in great abundance throughout the summer and well on into the autumn. Border chrysanthemums, pelargoniums and pentstemons were also shown by Mr. Case.

Among a collection of herbaceous plant Messrs. Hewitts were showing several of their famous Wrexham delphiniums. Ruffled Beauty, with its graceful tapering spikes of violet shaded mauve; and Rose Marie, pansy violet, were two of their best.

Some well grown hardy border plants came from the nursery of Messrs. J. Cheal and Son. Phloxes, such as Mrs. M. van Hoboken, a particularly good soft pink

Digitized by Google

variety; and Baron von Heeckeren, a rosy salmon, were noted.

Messrs. Ladhams staged some excellent new hardy lobelias, which are effective both in flower and foliage. Some of the new crimson varieties were brilliant in colouring. Shirley Crimson, Hamwood Pink, Purple King and Blue Bird were a few of these valuable border plants which were on show.

Pentstemons and herbaceous phloxes of good size and colour were exhibited by Messrs. J. Forbes. Asters, helianthus, delphiniums and an attractive Shatsa daisy, Iris Carlile, were shown by Mr. T. Carlile. Helianthus Loddon Gold, a handsome double form of the sunflower, was seen on the stand of Messrs. W. Keep; and a bold group of Kniphofia Mount Etna, shown by Mr. Isaac House, made a vivid splash of colour. Mr. House also exhibited a number of his beautiful scabious—Kenneth Ball, Harold, Clive Greaves and Millicent were all fine varieties, varying in colour from light mauve to dark purple. Daniel Bros. showed a splendid group of the large-flowered montbretia.

In the gallery, Messrs. Bunyard had a representative collection of herbaceous plants, both summer flowering and autumn flowering; Achillea Cerise Rose, Pyrethrums Albert Victoria and Agnes Mary Kelway, Sedum spectabile atropurpureum and many Michaelmas daisies; and Messrs. Blackmore and Langdon many fine spikes of delphiniums.

Some other exhibitors of hardy border plants included Messrs. G. Reuthe; Messrs. G. A. Miller; Messrs. Rich and Cooling; Messrs. Barr and Sons; Messrs. F. K. Wood; Messrs. H. Langridge; Messrs. W. F. Gullick, who showed border chrysanthemums, asters, kniphofias and pyrethrums; Messrs. W. Keep; Messrs. Skelton and Kirby; Messrs. G. Gibson; Messrs. G. Jackman; and Messrs. Wilson and Agar.

ROSES.

The competition for the Wigan Cup gave additional interest to the many exhibits of roses. The various groups were shown under numbers until after they had been judged. Most of the great growers had exhibits, so that the best blooms from Messrs. S. McGredy and Son, Messrs. A. J. and C. Allen, Messrs. B. R. Cant and Sons, Messrs. Frank Cant and Co., Mr. J. H. Pemberton, Messrs. Chaplin Brothers, Messrs. Alex. Dickson and Sons, Mr. Walter Easlea, Mr. Elisha J. Hicks and Messrs. A. Warner and Son were seen set out in friendly competition.

Generally, these large collections were admirable, and considerable time had been spent in their arrangement. In several instances the hard line along the front of the staging was most pleasantly broken by gentle cascades of beautiful roses hanging over the edge. The cup was won by Messrs. S. McGredy and Son, who had a lovely basket of Mrs. A. R. Barraclough, flanked by smaller baskets of the pink Ivy May, Mrs. Talbot O'Farrel, Patience and Desmond Johnson. Night, a very dark maroon, and Margaret McGredy, of glowing scarlet colour, were also prominent varieties.

The hybrid tea roses at this autumn Show were principally the same varieties as at the summer shows. So we saw gorgeous blooms of Betty Uprichard, Lady Inchiquin, Los Angeles, Shot Silk, Isobel, Colonel Oswald FitzGerald, Mrs. Henry Bowles, Mme. Butterfly and similar sorts. J. C. N. Mensing, described as the new pink Ophelia, is a very beautiful hybrid tea rose and was shown in goodly quantity. Messrs. Laxton Bros. were showing their rose Bedford Crimson, which is of a deep crimson colour and also very fragrant.

The dwarf polyanthas and taller cluster roses were somewhat in the minority at this Show, though there were occasional vases of Orleans Rose, Mrs. W. H. Cutbush, Koster's Orleans, Orange King, Edith Cavell and Queen Wilhemina of the dwarf polyanthas, and Moonlight, Felicia, Greta Poulsen, Pax and Penelope of the more robust type which bears larger, looser clusters of flowers.

STOVE AND GREENHOUSE PLANTS.

One of the most attractive displays of indoor plants was the beautiful group arranged by Messrs. John Peed and Son. With the graceful Humea elegans and slender palms, rising above many semi-transparent caladiums, highly coloured crotons, liliums, streptocarpus, Achimenes coccinea and hydrangeas they made a most charming exhibit.

Double-flowered tuberous-rooted begonias were shown in great splendour by Messrs. Blackmore and Langdon. This was the finest exhibit of begonias ever staged by the Bath firm, and was fully worthy of the award of the Coronation Cup for the best exhibit in the Show. The very beautifully formed flowers were of immense size and of pure colouring. Their varieties included Corientia, rose; Mrs. E. Ramsden, deep rose; Hilda Langdon, soft pink; Mabel Langdon, rich orange; Sir J. Reid, orange; Peace, cream; and Lady Ann, pink. In a large circular group Messrs. Sutton and Sons illustrated the excellence of their strain of double begonias. These were from seed sown in January of this year, and the plants were set out in radiating blocks of distinct colours. In addition to the large doubles they showed mixed colours of their Duplex strain. A large circular group was well filled with liliums, the bright scarlet Clerodendron Fallax and many floriferous little plants of Begonia semperflorens type by Messrs. Carter and Co. Messrs. R. and G. Cuthbert had a good selection of streptocarpus in many attractive shades of colour, and also included occasional plants of the glowing coloured Rochea falcata.

A number of uncommon fuchsias, flowering well in quite small pots, were shown by Messrs. G. Bunyard and Co. There were plants of F. gracilis and varieties, F. conica, F. Riccartonii, F. Thompsonii and F. Mimosa. Mr. Sydney Smith made an attractive display of cacti and allied plants. He set out examples of Opuntia robusta, Mamillaria perbella, Cereus flagelliformis cristata, Echinocactus Grusonii and other cacti, with an admirable selection of echeverias and mesembryanthemums.

Messrs. Stuart Low and Co. in addition to carnations, staged cannas, ericas, ailamondas and bougainvilleas.

FRUIT AND VEGETABLES.

As the Holland Park Show is fixed between the special Vegetable and Fruit Shows which are held at Vincent Square, there is no great need for these sections. Vegetables were represented by a collection of potatoes shown by Messrs. Thyne and Son. These were chiefly of seed size, but ware tubers were also included. The principal sorts were The Bishop, Kerrs Pink, Eclipse, Edgell Blue, Ally, Red King, King George and Mons Star, a new kidney-shaped tuber of pinkish colouring.

There were more exhibitors of fruit, which was fairly well represented. Mr. A. P. Brandt, Bletchingley Castle, sent eighteen handsome bunches of Muscat of Alexandria grapes, which already showed the desired amber tint which tells of high quality. These grapes were set out attractively with well grown crotons of useful table size.

Grapes were also shown by Messrs. G. Bunyard and Co., who had many neat, compact bunches. The berries were about the size of large black currants. Since the vines

WATERER'S ROSES

WE give to our customers the benefit of mass production methods combined with the high quality demanded of the specialist. Guaranteed of our own growing, these Roses are far superior to the Continental products which cause such disastrous results in English gardens each season. The seven varieties illustrated in colour—*Top Row* (from left to right) OPHELIA BETTY UPRICHARD, INDEPENDENCE DAY; *Bottom row* (from left to right) SHOT SILK, LADY INCHIQUIN, LIEUT. CHAURE, GOLDEN OPHELIA—are of great merit and can be supplied at **1/3** each, **14/-** doz., except SHOT SILK, which is **1/6** each, **16/6** doz. Our catalogue contains much valuable information and includes full details of our large collection.

Dwarf Roses	from	**14/-** doz.
Climbing Roses		**16/6** ,,
Standard Roses		**4/-** each
Half Standard Roses		**3/-** ,,
Weeping Standard Roses	from	**5/-** ,,

Orders for roses not in pots to the value of £1 and over, are sent carriage paid.

Please write for a copy of this Catalogue.

For further particulars, see our advertisement on page viii.

THE GARDEN

VOL. XCI.—No. 2915. OCTOBER 15, 1927. PRICE TWOPENCE.

OUR DEBT TO SPECIALISTS

IN whatever department of horticulture one's interest lies, it will be found that the best achievements are due to the painstaking and long continued work of the specialist, who, in many instances, works upon a plant of insignificant origin until he has produced, perhaps after several years' labour, something praiseworthy and quite superior to anything that has preceded it.

When people take exception to what appear to be enhanced prices for new varieties of plants when first they are offered for sale, it is doubtful whether thought is ever given to the many failures and disappointments the raiser had to encounter in the casting aside of plants which, on blooming, were found to be but commonplace, before he was able to evolve something that was really meritorious.

Much has been said in the last few years about the absence of scent from many modern roses, and there is truth in it; but if one compares roses to-day with those grown, say, fifty years ago, it is only right that the matter should be regarded all round. It must be admitted that some of the oldest varieties possess much sweetness, an attribute not found in a number of those introduced the last twenty years or so; but surely we have enough roses valued for their perfume to enable us to admire a Frau Karl Druschki, whose peerless white blooms are so beautiful, though lacking scent! The old growers knew scarcely anything about hybrid teas with their delightful colourings and shapely buds, and teas were looked upon and treated as indoor subjects mostly. They understood more about the hybrid perpetuals, and, in particular, such sorts as John Hopper, Baroness Rothschild, Dr. Andry and Gloire de Dijon, that never approached the charm and grace of a Betty Uprichard, a Mabel Morse, a Golden Emblem or Ophelia. If, as has been stated on more than one occasion, it is true that raisers of new roses are more concerned about form and colour than with perfume—an indictment with which we do not agree—one can afford to be charitable when it is realised what is due to these specialists for the feast of beauty they have provided for the lover of the queen of flowers!

When one is inclined to review some of the good old things of the past, and imagine that something of value has been lost, it is well to sit down and peruse a catalogue of a firm of seed growers and raisers, as there is nothing calculated to dissipate prejudice more quickly, if only the subject is approached with an open mind. A few examples will demonstrate what we mean.

What has the specialist done for us in the case of wallflowers? He has given us Sutton's Fire King, Vulcan, Orange Bedder, Eastern Queen (a blending of colours of apricot and carmine), Faerie Queen (primrose), Purple Queen, Cloth of Gold and Giant Blood Red, much superior to any old form. Of these it can be said that no charge can be made against them that they are lacking in sweetness. The chrysanthemum is a witness to the work of the specialist, too. We remember when, for the most part, it was only as a garden flower that it was known, our earliest recollection being of Cottage Maid, a ragged pink, and pompons of deep red and yellow. To-day one may have chrysanthemums in bloom from July to January, by choosing varieties for outdoor and indoor blooming.

A garden plant which blooms in late spring and early summer is the sweet william. The old florists made much of it, and rightly so, but it has been left to modern specialists to bring to our borders such superb sorts as Pink Beauty and Scarlet Beauty. The lupin is another old-timer of the cottage garden represented by blue and white. This plant has been raised from a position of comparative obscurity by reason of the work of the specialist. The Michaelmas daisy is another that was for years represented only by one or two forms—a slate-blue, a purple, and a white, lacking in purity. Now we have rich blues and indigos, rosy purples, and brilliant pinks, along with dainty members of the ericoides section, almost as fine as heather itself; some tall and imposing, others dwarf and of dainty habit. Mention need only be made of the improvements in other well known garden plants, like antirrhinums, clarkias, godetias, aquilegias, sweet peas and dahlias. The same progress is manifest among greenhouse flowering plants. One thinks of primulas, cinerarias with their dainty stellata forms, and also of the strides which have been made in begonias and cyclamen.

Among vegetables the work of evolving better varieties has been going on steadily for years. This is demonstrated in peas and beans; in lettuce and onions; in tomatoes and potatoes. All along the line it is the work of the specialist which has told for good, and because of his work we have no longings for the varieties of a past generation.

The Specialist's Aim.

There is one very important point between the raising and growing of seeds and plants that all concerned will do well to consider It is this. An inferior strain needs just as much attention and preparation of soil as the best. Is it not always more satisfactory in every way to get the best at the outset, even though the cost be a little more? Experience warrants us in saying that it is by far the most economical procedure, and that in the long run quality counts.

The specialist has ever in view this question of quality, hence the seemingly good plant of one decade has to make way for something in the next which has been found superior.

This Week's Work

For Gardens in the South and Midlands.

Prepare beds for roses and shrubs.

Plant tulips, anemones and ranunculus.

Fill window boxes with bulbs and wallflowers.

Plant raspberries, currants and other bush fruit.

Lift and store begonias and gladioli.

Store potatoes, beetroots and carrots in clamps.

Take cuttings of roses.

Plane peonies, delphiniums and lupins.

Finish pruning and tying in rambler roses.

This Week's Work

For Gardens in Scotland and the North.

Plant bulbs in window boxes.

Lift and pot tuberous begonias in leaf soil.

Transplant seedlings of spring flowers.

Make a first sowing of cyclamen.

Take up rhubarb for forcing.

Dig vacant plots.

Plant anemones and ranunculus.

Complete pruning and tying rambler roses.

Give cinerarias their intermediate shift.

Propagate dwarf polyantha roses from cuttings.

Thin shoots of gooseberry bushes.

Renovate arches and pergolas.

Digitized by Google

SUGGESTIONS FOR A SMALL ROSE GARDEN

A GARDEN consisting entirely of roses is a practical and desirable proposition, but an English garden without roses is inconceivable. No other flower combines the almost infinite range of colour gradation with a flowering period lasting from early summer to late autumn, and a fragrance unequalled by any other occupant of the garden.

It is not always, however, that roses are planted to the best advantage. One sometimes finds them in scattered masses mixed with shrubs or herbaceous plants, or in curious-shaped beds dumped at random into odd corners of the garden, but this is not doing them justice. The rose possesses so many attractions and is in a class so entirely unique that it demands a portion of the garden to be devoted exclusively to its cultivation.

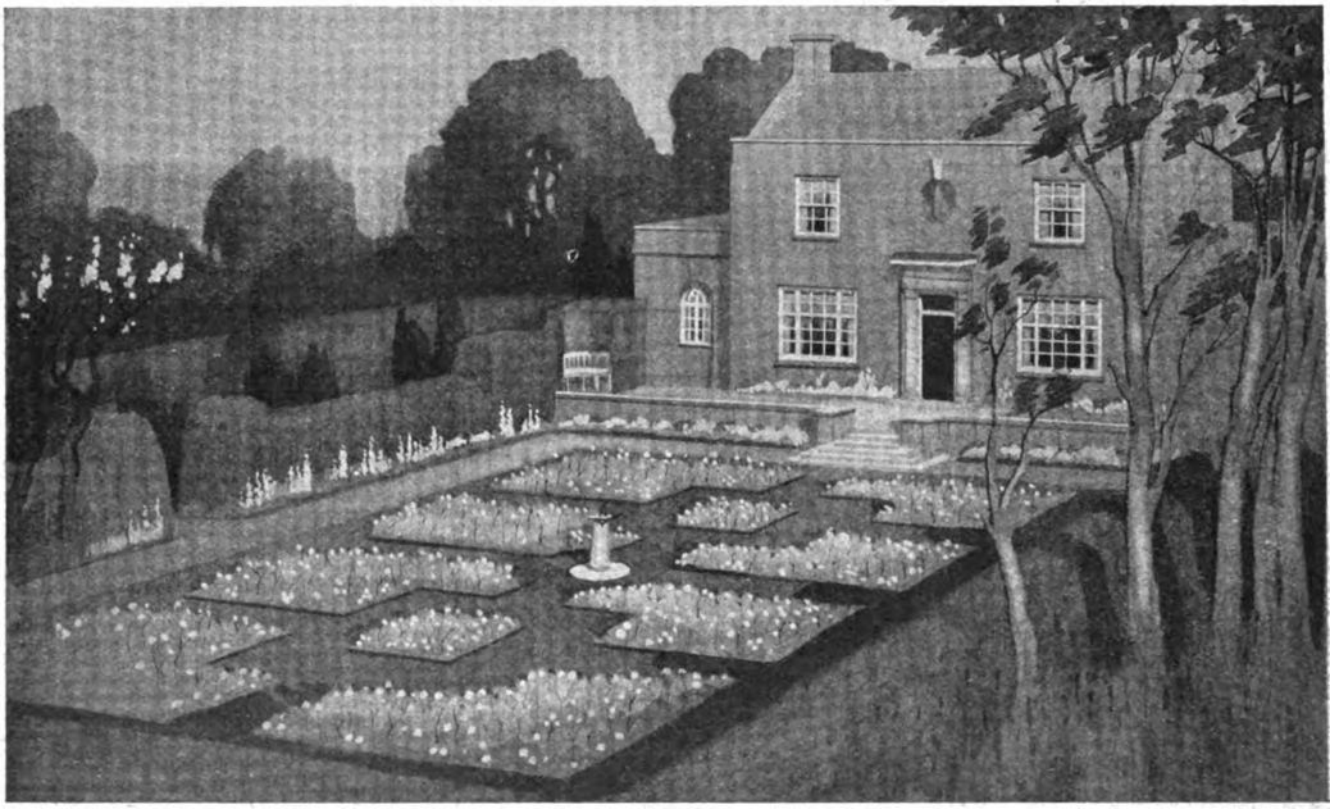
area to grow a very fine selection of roses. I always think that one cannot be too careful in combining the colours in a rose garden. Take, for instance, the crimsons and pinks. Planted side by side, these detract each from the other, whereas crimsons and pale yellows always unite perfectly. There is nothing to object to in the association of yellows and pinks, and the pinks and creams or very pale yellows make a very soft and happy combination.

In this little garden I am suggesting that the strong and warm colours are massed in the centre of the design, and thus we get four blocks of crimson connected to four of yellow, while in the interior they shade away to four smaller groups of bright scarlet. The isolated beds of orange will have the

to make dry paths inside this enclosure, I would restrict such an effort entirely to the surrounding path, that is, between the borders and the rose beds. I would urge strongly how important it is that this colour grouping should be seen, relieved by the cool green carpet of closely mown turf.

In such a design as is presented here it is necessary to introduce some central object, which can either be a garden ornament or a shrub, provided it is remembered that the shrub will grow, that the area is limited, and the choice must therefore be one which will not usurp the necessary width of path surrounding it.

With regard to the varieties which can be planted in such a garden, these would depend to a very great extent upon local conditions.



A ROSE GARDEN LAID OUT ON FORMAL LINES, AND SUITED TO A PLOT OF MODERATE DIMENSIONS.

Moreover, the rose is not a plant which cares to associate too closely with its neighbours. It has been called the Queen of Flowers, and it would appear from its objection to mixing with other plants that it realises its lofty position in the flower world and insists on that aloofness from common things which has always been considered, rightly or wrongly, to be a royal attribute.

There is a very strong argument in favour of making a rose garden one in which the lines are more or less formal, and this applies particularly to a situation where the area is somewhat limited. Roses look at their best when grown in blocks or masses of one sort, and this little formal garden, which I have designed to suggest a pleasant arrangement wherein at least twenty-two varieties of roses can be grown in such a way that each will assist the other by colour combination, can be modified to suit an area somewhat smaller or considerably larger.

The total area occupied by the rose garden is 50ft. by 25ft., and a glance at the plan will show that it is possible within such an

effect of keeping the central mass of warm colours to themselves. In the four L-shaped beds in the corners the pinks will be seen nearest the yellow, and will shade away to smaller groups of cream and very pale yellow.

If the area were a little larger, I should have preferred making the paths 5ft. wide instead of 4ft., because 5ft. allows two people to walk side by side, whereas 4ft. scarcely permits this. Also, if the area were a little larger the beds could be increased in size without destroying the cohesion of the elements forming the general design.

Now, a few words about the paths. In my design I have shown the whole of the rose garden lying in a lawn of mown grass, and there is not the slightest shadow of doubt that this is by far the most satisfactory effect, looking at it from the æsthetic point of view. If the garden is large enough to surround it as suggested in the plan by borders of either herbaceous plants or flowering and foliage shrubs, then any hard paths which are required can be placed outside these borders, but if the garden is so small that it is necessary

There is no doubt whatever that some roses succeed better in some localities than in others, and in making the following suggestions of varieties suitable for such a garden I do so with the idea that many people will have their own preferences with regard to varieties, and some of the sorts I mention will be better omitted on account of the local conditions.

Crimson.—General McArthur, Etoile de Hollande, Lord Charlemont, Hawlmark Crimson, Bedford Crimson, Hugh Dickson and Hoosier Beauty.

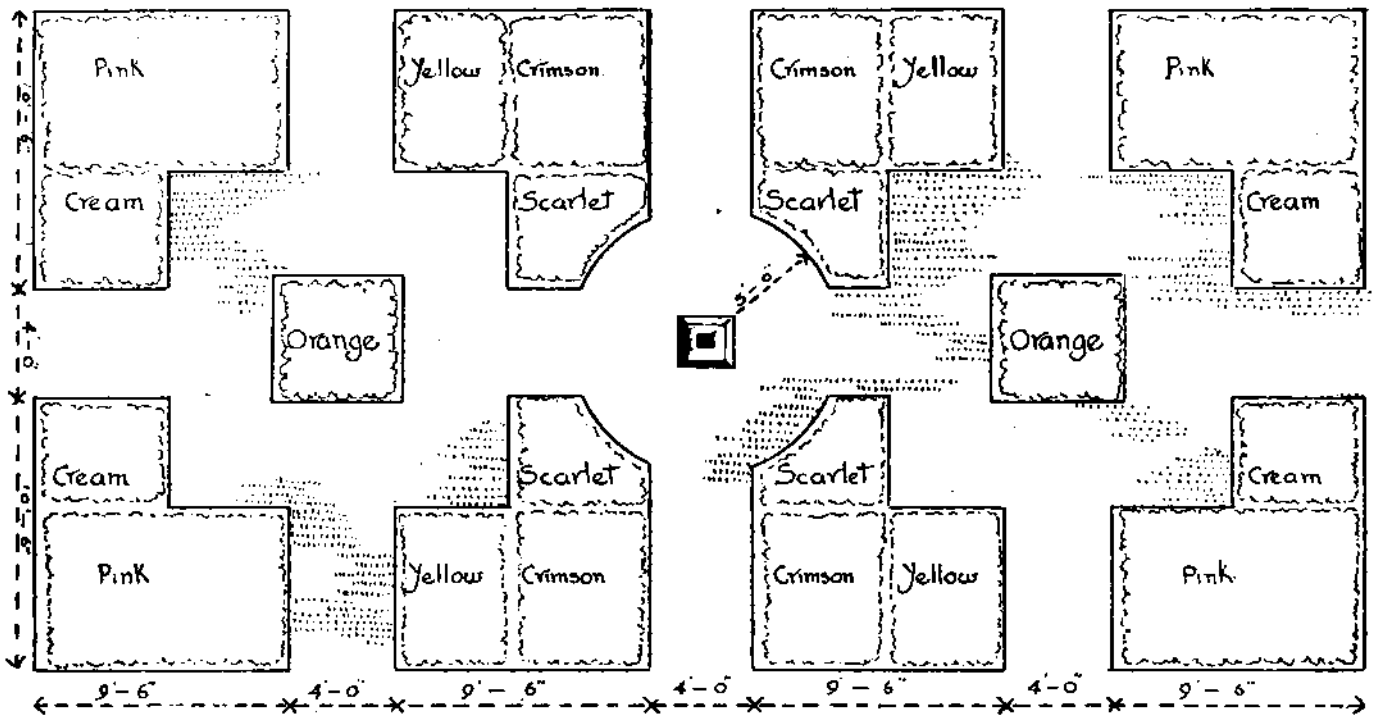
Scarlet.—Charles K. Douglas, K. of K., Hortulanus Budde, Red Letter Day, Château de Clos Vougeot and Covent Garden.

Orange.—Emma Wright, Sunstar, Independence Day, Irish Fireflame (single), Irish Elegance (single), Henrietta, Frances Gaunt, Flame of Fire and Lamia.

Deep Yellow.—Mabel Morse, Golden Emblem, Christine, Florence L. Izzard, Mrs. Beatty, Mrs. Wemyss Quin, Sovereign and Rev. F. Page Roberts.

Pale Yellow and Cream.—Elegante, Harry Kirk, Miss Willmott, Mrs. Beckwith, Melody, and Mrs. Henry Balfour.

Digitized by Google



THE PLAN OF THE ROSE GARDEN SHOWING THE COLOUR ARRANGEMENT.

Pink.—Mrs. Henry Bowles, Mme. Butterfly, Rose Marie, Mrs. Henry Morse, Mme. Abel Chatenay, Mrs. George Shawyer and Charles E. Shea.

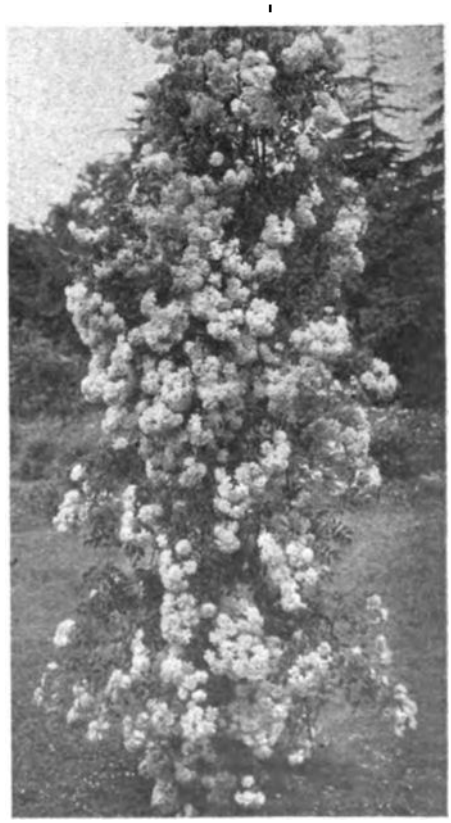
Salmon and Cerise.—Lady Inchiquin, Los Angeles, Cheerful, Mrs. Redford, Lady Dixon Hartland and Betty Uprichard (orange and salmon pink).

For such an arrangement as I have suggested the above is a sufficiently comprehensive list from which to select, but to say that it is even representative of all that is good in roses would be absurd. The actual choice of varieties must, therefore, be a matter of personal taste. G. D.

ROSES FOR PILLARS AND PERGOLAS

ROSES for covering pillars in a garden should be selected with care, preference being given to those the growth of which is staid, omitting sorts which, however attractive they may be for a few weeks when in bloom, romp away and completely smother the structure. Dorothy Perkins and varieties of that type are more at home on a pergola or dividing fence where there is plenty of room for the shoots to extend, but in the confined space of a pillar, whether it be one constructed of rough poles at the back of a border or placed near a wall, it is better to make a choice from some of the many sorts that are not so rampant. The season for planting is close upon us, and it may not be inopportune to consider the claims of some of them. I have noticed where it is not always possible to erect an arch or pergola in a gaden of moderate dimensions, room can usually be given up to pillars. The rougher and firmer these can be constructed the better. Larch poles make excellent supports, as do elm and ash if properly chosen. In any case the main supports which have to go in the ground should be treated with a coating or two of preservative in the nature of carbolineum, as then they will last for years. The dimensions of the pillar will suggest the number of plants to be used. As a general rule, it is much the best to plant only one sort at the foot of each pillar, as then overcrowding is avoided and it is easier to deal with a single specimen. November should, if possible, see planting done. If the position is one close up to a wall, more than usual care is needful to ensure a proper rooting medium. This can only be ascertained by digging out to a depth of 2ft., or even 3ft., the material, which, too often deposited under walls, is nothing more than rubbish, and this is one of the causes why some roses do not do well near a wall, because they have never been provided with a good rooting-ground. Drainage must be arranged for, and some of the rammel consisting of brick-ends and mortar rubble will answer. Over this, good loam and rotted manure should be placed, filling up with loam. In planting, the roots ought not to come in contact with manure, and each tree should be well trodden in after

BLUSH RAMBLER OVER AN ARCH.



LADY GAY, A FREE-FLOWERING RAMBLER.

Digitized by Google

planting has been done. Should the plants arrive from a distance and the weather is frosty o the ground is in a wet condition, defer the work for a time, keeping the bundle in a cool place, such as a cellar, covering them with a bag of straw to prevent drying. In planting, see that the hole is large enough to enable the roots to be spread out, and cover the roots with the finest soil, then filling up with rough. Tread well in, so that when the job is completed the plants will be firmly set in the soil.

Training.

From the time planting is done it is advisable to get the shoots into something like position, though pruning of them must follow in spring, the idea being to prevent storms of wind and rain unsettling or uprooting them before the roots have got hold. If this is not done, and the shoots left lying about the ground in winter, sometimes they become loose in the soil.

Varieties.

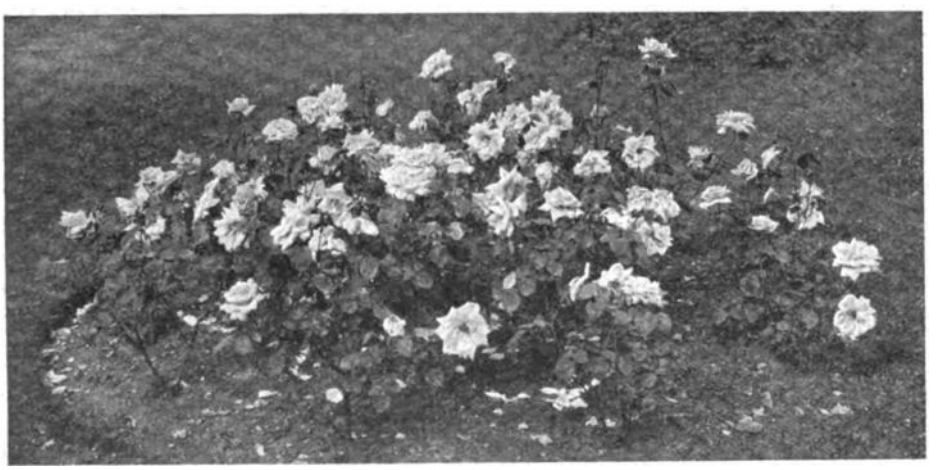
"The best show for the longest time" should be the motto of the one planting rose trees for the adornment of pillars, and though hat class of rose known as a rambler is very beautiful while it is with us, its season passes swiftly, and then begins the output of new shoots which are apt to envelope the pillar, although, if there is plenty of space available rambler roses should also be included, as they make a very effective display for several weeks. Some of them are old and well known; others whose names are just as familiar now come to us under the guise o. climbers. I give the names of a dozen from which one can make a choice for a garden: and in this list are some climbing fo ms of well known hybrid tea varieties: William Allen Richardson, deep orange yellow; Caroline Testout, rosy pink; Mme. Alfred Carriére, white, tinted flesh; Mme. Abel Chatenay, rose, shading to salmon; Rêve d'Or, buff yellow; Lady Ashtown, deep pink; La France, satiny pink; General McArthur, crimson; Trier, creamy white semi-double clusters; Lieut. Chauré, velvety crimson; Grüss an Teplitz, bright crimson semi-double flowers in clusters, with good foliage, a fine autumn rose for pillar work; and Paul Lede, carmine shaded orange. Among rambler rosessuitable either for a pillar or a pergola, one of the best is American Pillar. Lady Gay, a cherry pink variety somewhat similar to Dorothy Perkins, and Albéric Barbier are also good. The foliage of the latter variety is almost evergreen, and it produces its creamy white blooms early in the summer. For draping an arch or stone pillar, Blush Rambler, a mid-season variety, is particularly effective; so also is Emily Gray, which is considered to be the finest yellow climbing Wichuraiana rose yet introduced. Sander's White, in many districts, is very free flowering, and Jersey Beauty is a most attractive, pale yellow, single-flowered rambler. L.

HOW TO SUCCEED WITH ROSES

This is the first of a series of articles on roses, written by a well known authority, which will answer all points that make for success in the growing of roses. Amateurs should make a note of the points emphasised and endeavour to follow the suggestions given, which are the outcome of many years' experience. This article deals with preparation that should be made before the actual planting is done next month.

IN an ordinary season the planting of roses begins about the end of October, and if the weather is open—that is, if frost is absent—the work can be continued, as opportunity affords, until March. This year, however, the grower need not be worried if the plants ordered from the nurseryman do not arrive at the usual time. The reason is obvious. An unusually wet summer and autumn have been experienced and the plants, in consequence, are not likely to ripen up in time for removal at the end of October. If deliveries are somewhat later this year the purchaser may rest assured that the nurseryman is taking the precaution of holding up the plants until they are sufficiently hardened up for lifting.

It should be observed that plants with soft, green growths are almost certain to cause trouble. Bushes with shoots of such a character are sure to die back very severely when removed and replanted. If they are allowed, this year, to remain a little longer than usual in the nursery, the colder weather and longer nights will soon harden them up and render them fit for transplanting anywhere. Do not be impatient, therefore, if you experience an unwonted delay in the delivery of your plants this autumn. It is well to remember that your interests are at stake.



A FINE ROSE DISPLAY WHICH WELL ILLUSTRATES THE IMPORTANCE OF GOOD CULTURE.

It is to be assumed that the ground intended for the roses has been dug over and manured in readiness for planting, but if this work has not already received attention it must be carried out at once if planting is to be done in November. It is always desirable to allow the soil time to settle before planting is done. It is most undesirable to dig over the ground for the roses and then to plant immediately afterwards. When planting is done shortly after digging and manuring the soil is inclined to subside, and the plants are apt to be left too far out of the ground as the result. Two very dangerous consequences ensue. The first is that the point of junction with the stock and scion is exposed to all weathers and the plant may perish, or, if it survives, it will make but poor growth in future. The second is that the plants become loosened in the soil and are at the mercy of every winter wind. Root action is disturbed and the plants will surely die.

Manuring.

The question of manuring is one of extreme importance, and I generally find that the average amateur is too often inclined to be far too generous in this respect to newly planted roses. The ideal manure for the cultivation of the rose is well rotted cow manure. That material, unfortunately, is not easily procured by many growers, and in such cases a substitute is necessary and has to be found for it. If cow manure can be obtained it ought to be applied very sparingly. The soil in the beds or borders should be "bastard trenched," and at the foot of the bottom spit put in a dressing of 4ins. or 5ins. of the manure; at the bottom of the top spit place 3ins. of the same material, adding, at the same time, a sprinkling of rough bone-meal. When the work is finished allow the bed to settle down for at least a fortnight before planting.

If cow manure is not procurable, material from the stables may be substituted. If horse manure is used, be careful to employ only that from stables where straw or something similar has been used for bedding. Peat moss litter is a dangerous manure for roses. The peat does not decay readily and soon becomes sour. In such a state it sets up unhealthy soil conditions; the roots become sickened and the plants deteriorate rapidly. Pig manure will answer, but, as with other manures, it must only be used in a well rotted condition. In the absence of cow, horse or pig manures, something must be used to provide humus in the soil. Leaf-mould or decayed spent hop manure will do, but these must be supplemented by bone-meal applied at the rate of 4 oz. to the square yard of surface.

It is a somewhat difficult subject to deal with manures, because conditions vary so much in gardens, and so, also, do soils. What may be good in one garden is more than likely to be bad in another, and of all plants none is more impatient of unsuitable soil conditions than the rose. It is not the gross feeding plant that many folks imagine it to be, and it cannot tolerate too liberal nor yet too poor manuring. A happy mean must be struck. If you can grow herbaceous plants successfully, if you can produce good cabbages or cauliflowers, you need not despair about roses.

It is the desire of this article to assist amateur growers in every possible way, and Those who have had difficulty in the cultivation of roses are invited to write to the Editor and inform him just where the trouble has arisen, what manures have been used and how often applied. The information so obtained will be carefully considered, and the replies and advice thereon will be very helpful to many besides the person who sends in the details. It is, I think, by such means that help can be

Digitized by Google

given to the amateur, and such information is far better than mere mechanical writing upon the subject.

The next article will deal with actual planting, and if any readers send queries in regard to soils and manuring, these will be answered as fully as possible. The different types of roses will be dealt with, and this is also a point of importance. The modern rose is an exceedingly complicated organism. There is a type which is exceedingly prone to mildew; one which is addicted to black spot; one which grows too tall for ordinary bedding work; and one which has a poor constitution. The modern bedding rose is classified, for the most part, under two general types, *viz.*, hybrid teas and Pernet roses; but in both sections there is considerable variation and a vast difference in the manners and customs of the sorts comprised in them. There are, however, many varieties of sterling merit which have been proved after thorough trials, and it is with such roses that we are concerned.

GEO. M. TAYLOR.

AN UNCOMMON GARDEN SCHEME

There are many suburban gardeners whose main endeavour is to get away from the too obviously rectangular outline of their fairly long and "unfairly" narrow garden plots. Here is a suggested plan which you may like to adopt when carrying out alterations this winter.

WHERE the whole of such a garden is to be devoted to flowers, the end farthest from the house may be laid out on informal lines, and really skilful planting will largely, or even entirely, obliterate the rectangular feeling. The part nearest the house, however, calls for more formal treatment, and here curvilinear outlines may be usefully employed with the same object. The accompanying plan shows a simple lay-out on these lines, of vistas—to flowering shrubs. Barberries, escallonias, brooms and shrubby veronicas are particularly suitable as being—or, in the case of the brooms, appearing—evergreen. The climate being suitable, some of the choicer olearias are also very desirable for the same reason. One would not, however, confine this planting to evergreens. Care should be taken to see that all the kinds employed do not flower at the same season.

The selection of the lighter—generally speaking, herbaceous—planting in front of these shrubs is one calling for great care in a garden so small as that shown. Bearing in mind the association with dwarf walling and paving, shrubby and sub-shrubby kinds with grey foliage can be used with great effect—lavender, santolina, Jerusalem sage (Phlomis fruticosa), Olearia stellulata and some others of the New Zealand bush daisies, with, soil and aspect permitting, some of the dwarf rhododendrons, such as RR. racemosum, hippophæoides, intricatum and fastigiatum. Cistus and helianthemum likewise provide many good grey-foliaged shrubs and shrublets, which are most effective when in blossom and continue to flower for a considerable time.

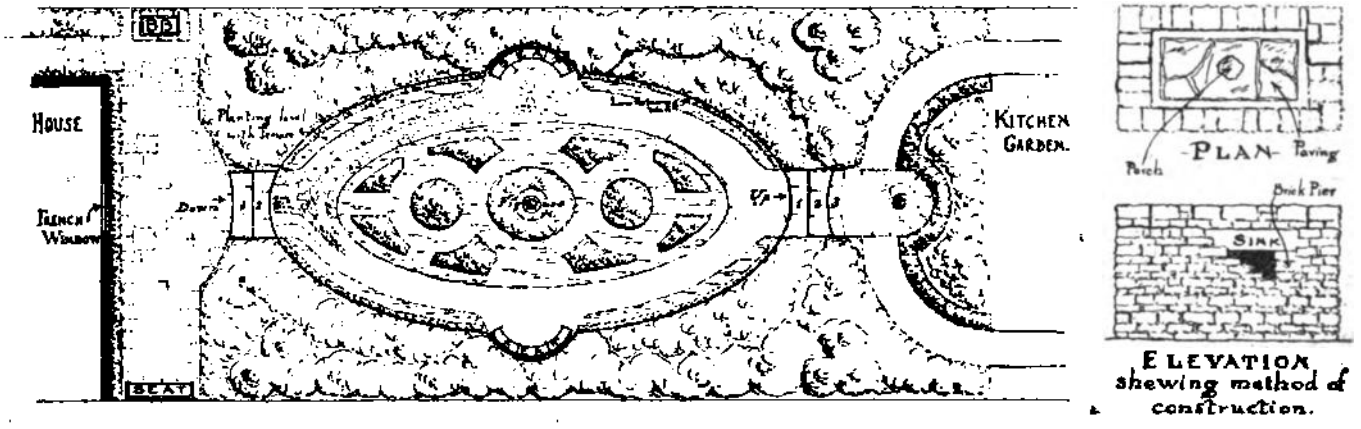
With such "permanent furniture" one may associate many choice and beautiful herbaceous kinds: Dwarf anemones, dog's tooth violets, fritillarias, the Carpathian snowflake (leucojum), crocus species and such-like for early spring effect; tulip species, May-flowering tulips and forget-me-nots, aquilegias, lupins and many forms of iris (bearded and otherwise) to usher summer in; lilies, gladioli, certain primula species, Galtonia candicans, many choice kinds of campanula and geranium, Pentstemon barbatus (the salmon pink form) and P. heterophyllus, some thalictrums and galegas, and a few good delphiniums to provide colour in high summer; and phloxes, a few of the best Michaelmas daisies and early-flowering chrysanthemums, and some of the elegant star and mignon dahlias to brighten the shortening days. These are, of course, only suggestions.

The beds of the sunken garden might be planted with roses, taking care to select sorts which flower freely and, as far as may be, continuously. The planting of the sunk garden should, whatever its character, be kept fairly dwarf—at any rate, as regards the main weight of planting. A little diversity in the shape of an occasional standard rose (if roses are the main planting) or of clumps of the hardy agapanthus (Mooreanus), gladioli, galtonia, thalictrum, torch lily (kniphofia) or other slender, aspiring kind can, however, do no harm.

A yew hedge is suggested to screen off the kitchen garden, and this hedge might be backed with a few small trees or tree-like shrubs. Silver birches are very effective in such a position in localities where the soil suits them. Or Cotoneaster frigida with its wealth of crimson scarlet fruits might be employed, or, again, one of the fine forms of Buddleia variabilis, or flowering cherries, Malus floribunda—to take but a few examples.

The site for the bird-bath, BB, would not be suitable for a seat owing to its proximity to a draughty entry, and the usual and perhaps too common type of circular bird-bath would not fit in very well in this position. It may, therefore, be worth while to show how an old stone sink or pig-trough, such as may still be picked up cheaply in many builders' yards, can be utilised effectively for such a site. The sink is raised on piers of brick or concrete so that its top is about 2½ft. above ground-level, and is surrounded by a wall of "coursed random" walling stone of the kind so suitable for dry walling, but in this case jointed in mortar or cement. The walling should show to a thickness of some 6ins. in front of and behind the trough, and to about 9ins. at the two ends. The back wall is shown carried up 6ins. above the top of the sink and almost half the length of the flanking walls is similarly treated. These sinks, as "found," are usually too deep for a bird-bath, and the water area should be reduced by covering the bottom with a layer of "crazy" or other paving.

R. V. G. W.



A SUGGESTED PLAN FOR A PLOT OF RECTANGULAR OUTLINE.

Digitized by Google

THE BUSY MAN'S PAGE

The Best Vegetables for the Busy Man.

THE best selection of vegetables for the busy man is, we may take it, that which needs the least "niggling" work, such as thinning seedlings, spraying (for which reason broad beans are out of court), or slug-hunting. The following list is, therefore, a good one.

Peas (a good succession is Pilot, Lincoln and Gladstone), runner beans, perpetual spinach, leeks, shallots and, if space permits, sprouting broccoli.

Of these, perpetual spinach and shallots might almost be described as "labour-saving vegetables," since they not only require very little attention when growing, but are equally obliging in the matter of cooking! Perpetual spinach, if stripped from the midrib, cooked in a minimum quantity of boiling water with plenty of salt, pressed dry and finished with a dash of vinegar, pepper and a little butter, is delicious; while the shallot has the delightful characteristic of cooking in far less time than the onion, so is invaluable for "hasty, tasty" dishes, and has the additional advantage of being particularly mild flavoured.

Shallots should be grown from sets, which can be obtained in February for about sixpence a pound. The ground should be well broken up and liberally sprinkled with wood ash, soot and lime some time before planting. The sets are simply pressed into the earth. If winds are high and rains heavy at the time, it may be well to ridge up the earth round them, hoeing it away later when they have taken hold. The crop requires practically no further attention, beyond an occasional hoeing between the rows to keep down weeds, and is ready for harvesting about the end of July, when the whole crop can be lifted, dried off, and stored on wire trays or hung up in muslin bags in a dry shed for winter use. One pound of sets is sufficient for two 15ft. rows, and produces about 12lb. of shallots.

Peas are the most troublesome of the group, as they must be protected from the onslaughts of birds by black cotton, and subsequently provided with pea-boughs. The best way is to cotton them when they are sown, using at each end of the row a piece of board about 8ins. by 4ins., studded with nails round the edge and firmly fixed to a stout peg to be driven deeply into the ground right up to the board. This method is quicker and neater than using short twigs, as it is only necessary to pass the cotton round the nails at each end of the row instead of creeping along from twig to twig bent double. If the trench has been well dug and enriched with well decayed manure, the peas will need nothing but an occasional hoeing to ensure success.

Leeks are easily grown from seed, and a very small drill of seed will furnish enough young plants for two 15ft. rows; or young plants may be obtained in July from any market gardener. The trench should be prepared as for peas, with the addition of a sprinkling of wood ash, soot and lime. Plant 8ins. apart, leaving a ridge of earth at the back of the trench, to be hoed in by degrees as the plants grow.

Young plants of purple or white sprouting broccoli are easily obtained in August and should be planted in well prepared ground about 3ft. apart. They provide a pleasant change of green vegetable in the early days of the year, when greens are scarce, and have a useful "cut and come again" habit which makes them worth the room they take. They are also useful as a "wind-break" to other things. An early mint bed for instance, so sheltered, can be persuaded to provide mint quite a month earlier than one not so protected.

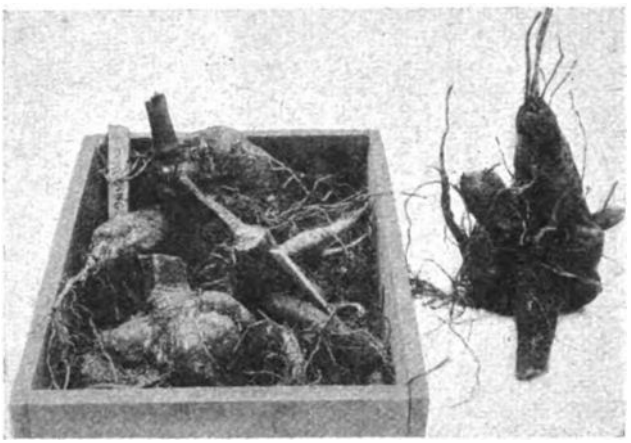
THE METHOD OF LIFTING DAHLIA TUBERS.
Dahlias should be removed when the foliage becomes blackened by frost. Lift carefully with a fork and do not injure the tubers.

Lifting and Storing Dahlias.

WHEN the foliage of the dahlias have been blackened by frost, the root-stocks may be lifted, turned upside down for a few days to drain, and then stored in boxes in a dry, cool, frost-proof shed for the winter; but it is desirable to spread cool litter, such as leaves or ashes, over the crowns before severe weather comes.

Standard Rose Trees.

ALL growers do not succeed in making this type of rose the success it ought to be. It must, first of all, be carefully planted in a well chosen site. Deep planting must be avoided at all costs; a shallow hole is made in soil previously well dug, the roots are then uniformly spread, and good rich soil is tramped firmly on top. A stake is always necessary, otherwise the strain on the roots is excessive and detrimental to the bush. Manuring later on should be on the top of the roots and beyond them; this encourages a fine and extensive system of feeding roots, a most necessary thing. Although pruning is on the lines followed in pruning bush roses generally, it demands an expert eye, for shape is of prime importance in the matter; the bush must be shapely without being heavy. When cutting the twigs back it is not wise to cut back into two year old or three year old branches unless necessity demands it, and strong shoots at the side need to be trimmed to two buds. In winter, very often protection is advisable, if not necessary; fine "heads" may be tied up merely or tied up with a little straw or some ferns, the protection being required more in the centre of the bush than at the tips of the branches. Standards are always expensive bushes and, if for no other reason, they ought to have the care we urge is necessary. They should be ordered early, too, as they are frequently rather scarce; and if the buyer gets a choice he should select those with plenty of fibrous roots.



DAHLIA TUBERS STORED IN A BOX.
The tubers on the right are turned upside down in order to enable the sap to drain away.

Storing Potatoes.

UNLESS a large quantity of potatoes have been grown, they can be stored in a dry, frost-proof shed, simply covering the heap with sacks. If a larger quantity is grown, store them in a "pie" on the driest part of your land. Make a heap of the tubers. Cover them with straw or leaves, about 4ins. thick, and then throw soil over the heap.

Make a vent hole at the top of the pie with a handful of straw or a few crumpled newspapers. The tubers will then keep well in the pie until required.

Care of Chrysanthemums.

CONSIDERING that the chrysanthemum blooms during the dull period when summer flowers have passed away, it now deserves every attention. It has the further advantage of being both an indoor and outdoor plant. To produce fine blooms on chrysanthemums growing in the greenhouse all side growths and buds should be removed, leaving only one or two at the top. Apply liquid manure from time to time. This is easily provided by suspending a small bag containing soot, sheep or fowl manure in a tub of water. The soil around the border plants should be stirred frequently, and not allowed to get set, otherwise the roots are deprived of the full advantage of the sun and rain. It is very necessary to see that the outdoor plants are securely staked, otherwise they will be sevesely damaged by the autumnal gales. All side shoots of chrysanthemums growing in pots should be tied loosely, but securely, to a stake.

Protecting Delphiniums.

IN some damp and heavy soils delphiniums suffer severely from the attacks of slugs in winter and early spring. When the stems are cut down in autumn some ashes may be spread round the stools to dispel the slugs.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Floral Hedges to Plant Now.

THE "season of mists and mellow fruitfulness" is the time when gardeners think of planting, for trees and shrubs of all kinds are best planted in early autumn, just when the leaves are "on the turn." While we may prefer to see spacious open lawns between our houses, the problems of stray animals and mischievous young children can only be solved by putting in hedges of some sort. But beauty can be combined with utility, and such atrocities as brick walls with broken glass tops should give place to well kept evergreen hedges. Such a shrub as Berberis stenophylla is both effective and charming. It makes thick growth from the base, is covered with tiny evergreen leaves, and in springtime each shoot is smothered with small orange flowers, which last for many weeks. The only pruning necessary is to cut back the straggly shoots after fruiting. This shrub is only one of many recently introduced that can be used for hedges.

Escallonia macrantha is another good hedge plant, which likes a dry and not too exposed situation. The narrow-leaved bay and Phillyrea angustifolia are also excellent. Another plant which deserves to be more widely grown, if only because it flowers so well in the dark days of winter, is the laurustinus (Viburnum Tinus)

Shrubs for Covering Walls.

THE town garden has often a tall, ugly wall at the far end, and, no matter how beautiful and well cultivated the garden may be, the wall always detracts from its beauty. There are many climbing shrubs that can be usefully planted to hide the bareness of such a wall. One of the best for the town garden is Fire Thorn (Cratægus Pyracantha). It does, of course, require training, but against the grimy blackness of a brick wall its shiny red berries add a touch of colour in the dull season of the year, and its dense foliage completely hides the wall.

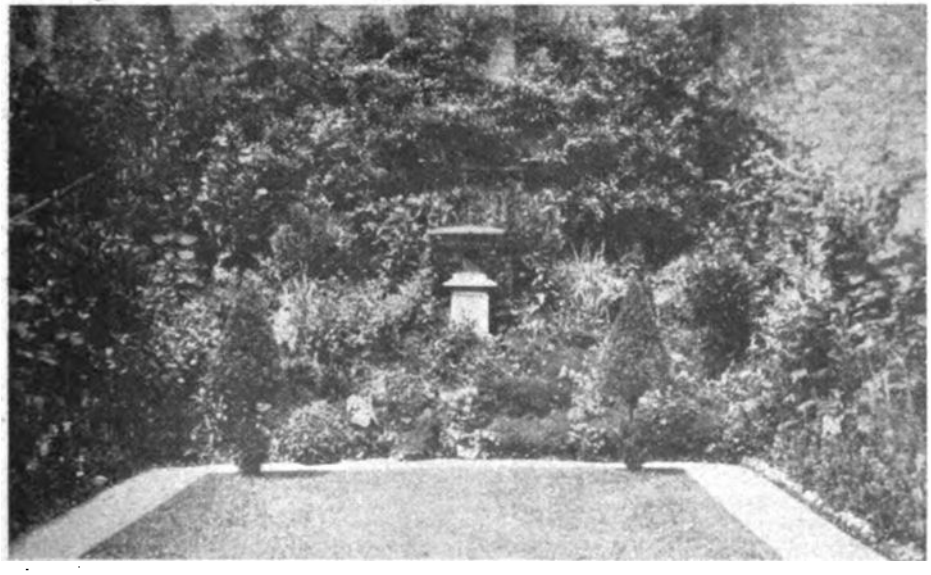
Another idea worthy of adoption, shown in the accompanying illustration, is the narrow rockery at the foot of the wall. This enables many charming plants to be grown in a small space.

About Weeping Standard Roses.

THE sight of a well grown weeping standard at the height of bloom can scarcely be surpassed in any garden, but one must exercise the utmost care in the placing of such specimens. Here and there on a lawn, planted in a circular bed 4ft. to 6ft. in diameter, such standards look at their best, but avoid framing a lawn with circles of them all round the outside edge. Weeping standards should be strong enough to grow naturally, *i.e.*, without being tied to any umbrella support. The rose should throw sufficient new shoots every year, each reaching the ground, and when in bloom completely hiding the briar stem. Liberal treatment with a thick dressing of manure in spring, lightly forked in, and a few cans of liquid manure applied during the growing season should give the desired result in growth, provided, of course, the plant was a good one originally and properly planted, with plenty of organic food for its roots to get at.

Most of the Wichuraiana roses, practically the only suitable type for weepers—throw their new shoots from the base, in which case *all* thin old wood should be cut clear out. For all-round excellence there is nothing to beat Albéric Barbier. Evangeline with its fragrant pink blooms is also good (some of the one-year wood should be left when pruning this rose and cut back slightly).

A RAMBLER ROSE TRAINED AS A WEEPING STANDARD MAKES A DECORATIVE CENTREPIECE FOR A SMALL BED.
Pink geraniums are planted round the edge of this bed.



PYRACANTHA MAKES AN ADMIRABLE COVERING FOR A WALL.
In this flower garden it is used to advantage to screen an unsightly wall.

Sander's White, Excelsa, Hiawatha and Jersey Beauty are all suitable.

Transplanting Evergreens.

IN most gardens there comes a time when "evergreen" shrubs have to be moved, either from a local nursery to the garden, or from one part of the ground to another. These plants are more difficult to transplant safely than those which lose their leaves in autumn. The reason for this is that the evergreens continue to give off moisture from the leaves, even in winter; while the removal, naturally, causes a check in the supply which should be coming in from the roots.

The present time is the best for moving such things as hollies, laurels, holm oak, rhododendrons, heather, etc., particularly while the days are warm and moist. It is essential to retain as much soil round the roots as possible. With rhododendrons and heather the root system can be moved almost intact; but with those which have rambling roots, as large a "ball" of earth as possible should be moved with them.

Bulbs in Grass.

A COLONY of daffodils in the grass at the foot of a tree is a joy in springtime. Those who have little time for gardening will find this an easy way to grow bulbs, for they flower year by year without needing much attention. Take a handful of bulbs, and scatter them where you think best. Cut a hole in the turf where each bulb lies, plant the bulb underneath, replace the turf and make it firm. This cannot be done where a very trim lawn is wanted in the early spring, as the bulbs must be allowed to flower and die down before the grass is cut; but many an odd nook can be transformed by a few spring bulbs planted in this way.

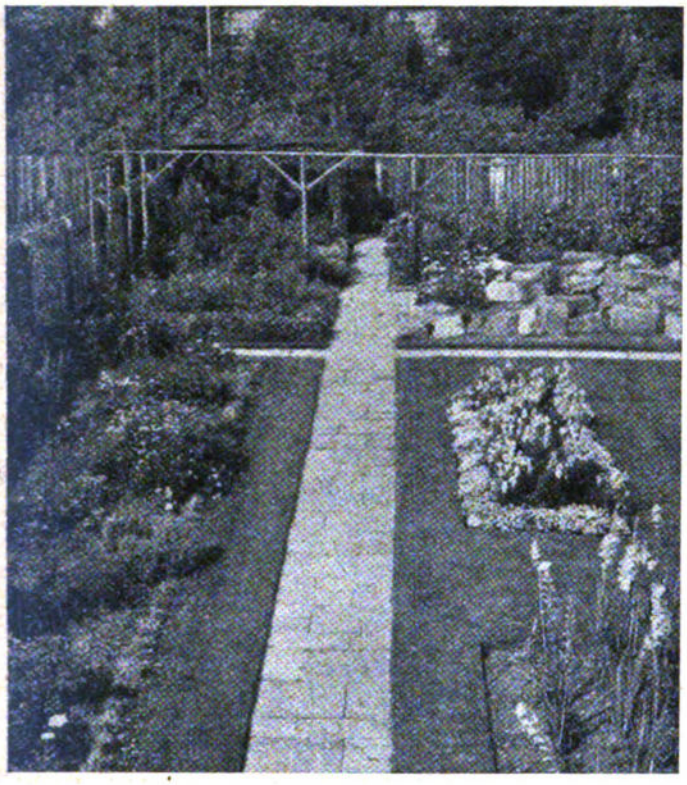
DESIGNS FOR YOUR



A GARDEN WHERE STRAIGHT LINES PREDOMINATE AND EVERY FEATURE IS IN PROPORTION.

WHERE SMALL PIECES OF STONE OF IRREG WITH CRAZY PAVING AND FLOWER BED

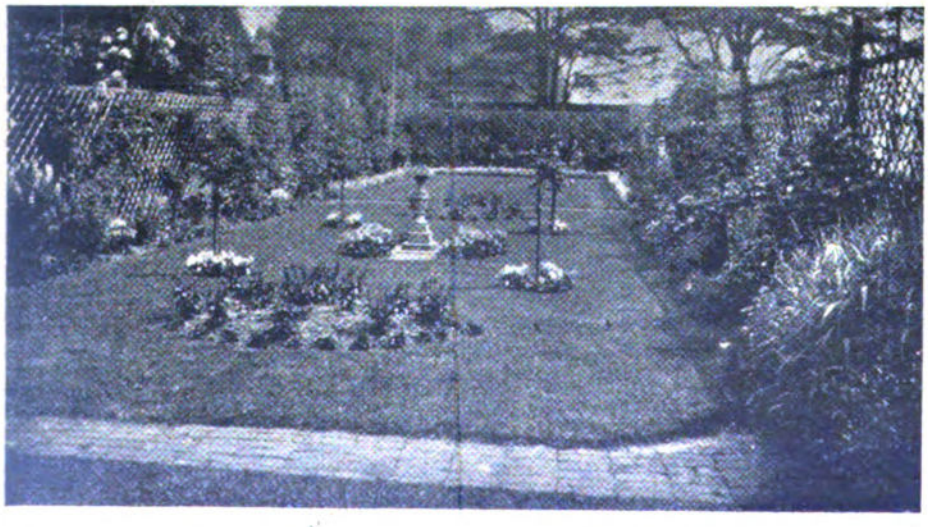
Our illustrations of plants growing in several of our readers' gardens, which were published in our issue of October 1st, have, we are pleased to say, stimulated others to send in photographs of their gardens. Of these we reproduce several which illustrate garden design, since this is an aspect of garden work that calls for attention at the present time, when many readers are doubtless thinking of making alterations in their garden scheme. These illustrations, all forwarded by readers, may serve to furnish others with ideas and so help in building up that bond which it is our desire to establish among our readers. It is only by an exchange of personal experiences among our readers that others who are only beginners in gardening may hope to benefit by the publication of photographs. THE

HERE is a small portfolio of a number of our reader's gardens selected principally to show their design or how a part of the garden has been laid out.

Design in a garden is largely a matter of personal taste, but there are one or two points to bear in mind when laying out a garden, however small. As far as possible the house and garden should be at one with each other. The design of the garden should conform with the architectural lines of the house, or at least that portion immediately surrounding the house, and for that reason should be laid out in a formal or semi-formal way. As the distance from the house increases more latitude can be allowed and the design can assume any particular shape desired having regard to the situation of the ground. The smaller the plot of ground is, the more difficult it is to design with any originality. The essentials must be included, such as a small border and flower beds and borders. Other features as, for example, a small rockery, bog garden or vegetable plot can only be included if there is sufficient space. It is not advisable to try to crowd several features into a small space, as the result will be far from satisfactory. The more simple the design the more charming the garden. For that reason there should be an absence of scalloped edged flower beds with meandering paths that lead nowhere. Never erect a feature such as a trellis for roses unless it is serving a useful purpose, such as a screen between one part of the garden and another.

Naturally, the situation of the garden governs design to a certain extent, but if a selection of plants is made judiciously and planting done properly, the difficulties of situation, exposure and soil can largely be surmounted while still keeping to a design. When a new plot of ground is purchased the task of laying out a garden should not be tackled straight away on the ground. It is much better to draw up a scale plan of the garden on paper. If there are any existing features on the ground, such as one or two tall trees or low shrubby bushes, do not remove these until it is seen if they can be made to serve a useful purpose. It should be remembered that these features may result in the production of a charming and uncommon garden. Above all, when designing be guided largely by your own personal taste. Never accept advice unless you are certain that you will like the suggestions when they are put into practical effect.

The first illustration is from a reader in St. Albans. It shows a garden which is laid out on simple lines with straight paths and rectangular flower beds, thus demanding less time for upkeep. A lawn adjoins the house and is surrounded



WALLS AND FENCES CAN BE MADE A VALUABLE ASSET OF ANY GARDEN IF SUITABLY CLOTHED.

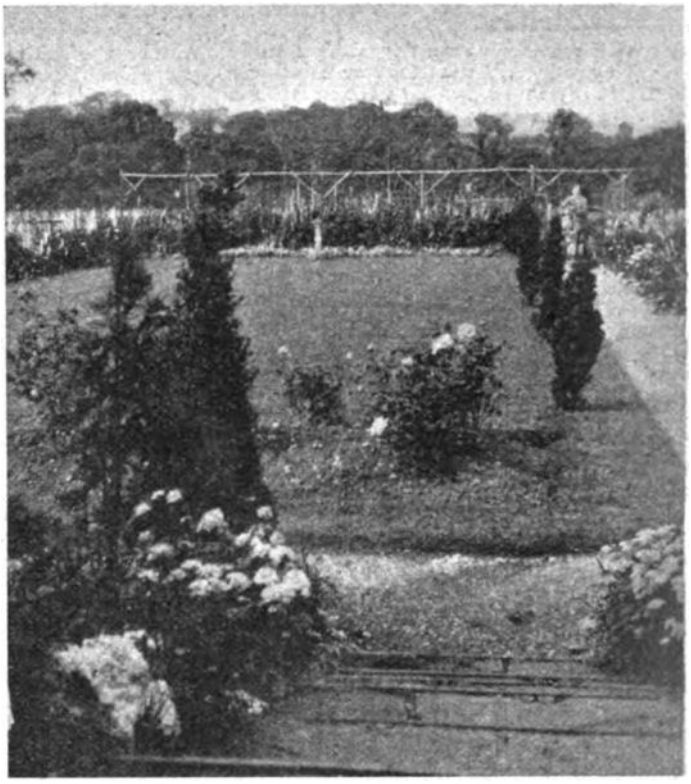
NEXT YEAR'S GARDEN

GULAR OUTLINE ARE AVAILABLE, A DESIGN S MAKES A PLEASANT HOUSE SURROUND.

GARDEN exists for exchanging ideas and personal experiences. Our recent Photographic Competition proved that readers appreciate this fact. We hope that, notwithstanding the close of the competition and the approach of unseasonable photographic weather, all our readers who are photographers will forward photographs, either of their gardens or plants growing in them, along with an account, so that others may derive benefit from their publication. These photographs should, if possible, be of topical interest, such as these on garden design published now. Other readers can, therefore, glean useful suggestions and ideas from them that can be put immediately into practical effect. Payment, it need hardly be stated, will be made for all photographs published in this connection as for the competition.



A FAIR-SIZED LAWN ALWAYS CONVEYS AN AIR OF SPACIOUSNESS TO A SMALL GARDEN.

by a stone path of sufficient width to allow two people to walk abreast. Behind the lawn a small rock garden has been made, and this is filled with a choice collection of rock plants. A trellis with climbing roses has been erected beyond this to screen the vegetable garden from the flower garden. At the far end is a tool and potting shed which can scarcely be made out by reason of its drapery of Polygonum baldschuanicum. The border running alongside the path is of the correct width in proportion to its length, and once the plants become established it will provide an effective display.

The centre illustration comes from Mr. A. E. Restarick of Felixstowe, and indicates what may be created in two years from a sandy waste near the sea. Crazy paved paths were laid down here as being more economical, and they look most attractive with patches of stonecrop flourishing in the cracks. Again a trellis has been employed to screen off the paved garden from the lawn and the raised rock garden at the far end.

The large lawn with its edging of ornamental conifers and long rose bed in the foreground makes a striking feature of the garden of Miss Harris of Birmingham. It gives an air of spaciousness to the garden. Wide flower borders flank it on either side, and each is filled with a wealth of herbaceous perennials.

The use of trellis and wall plants as boundaries to a garden is well seen in the illustration from Mr. Perrott of Chelmsford. Two separate stretches of lawn are laid out with beds of bush roses, and standard roses surrounding a sundial lend a most restful effect. The well filled straight borders and the furnished trelliswork give finish to what is a simple and yet attractive garden.

Although only two years established, the garden of Mrs. Rodwell of Tunbridge Wells has a mature appearance. It is of uncommon design with its strips of grass divided by a broad paved path with a bird bath as a central feature. The raised rockery bank round the lawn is effective, and the alteration in the levels has been skilfully treated. The stone steps lead through a trellis with rambler roses to the vegetable ground which is thus well screened from view.

Our last illustration, from the garden of Miss Austin, Wellington, Shropshire, may serve as an idea to many of how to treat a small raised bank surrounding the house. The lawn has been allowed to slope away from the house and in order to give a finished effect to the house surround this small rockery has been built. Water from an old fountain has also been introduced into the scheme so that the attractive rock and water garden has been formed, which continues a bright display of colour and blossom almost all the year round.

N, IF WELL PLACED, LEND DISTINCTION LE DESIGN.

THE LOW ROCKERY BANK IS A CHARMING FEATURE OF THIS HOUSE SURROUND.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

THE remarks concerning dahlias made by Sir William Lawrence at the luncheon connected with Holland Park Show, as reported in the daily Press, have, naturally, created a feeling of resentment among Scottish growers. People of a charitable disposition conclude that the Treasurer of the Royal Horticultural Society is not familiar with the modern types of decorative dahlias and that a profitable visit might be paid to several of our leading nurseries where a speciality is made of dahlias.

Now that the summer bloom is over, window boxes can be cleared of their present occupants and replaced by bulbs that will provide a floral display in spring. Tulips, hyacinths and daffodils are alike suitable, but in the higher and more exposed positions of an upper flat, the latter are preferable, as they are less liable to be damaged by the March winds. Besides, the self yellow and bi-colour flowers of the large trumpet and chalice cup types associate nicely with the dark shades of wallflower, a combination that prolongs the period of bloom. Snowdrops and grape hyacinths produce a pretty blue and white effect, and if a bright splash of colour is desired, try a box planted with Kaiserskroon tulips. Mixed wallflowers, also, look well and probably stand longer than any other spring flowering subject, and a pleasing colour scheme may be produced by arranging myosotis (forget-me-not) as an edging to a box filled with Vulcan, Bronze King, Ellen Willmott or other dark shaded variety of wallflower. Unsatisfactory results are frequently caused by the condition of the old soil, which becomes sour by reason of imperfect drainage and repeated watering in summer. In many cases the soil of a window box is not renewed so often as it should be, and overcrowding contributes to the depreciation of the rooting medium. Soil that has remained in a box for more than a year should now be replaced with a light, rich compost of loam and leaf soil that has been made porous by the addition of sand, and while it is essential that the bulbs should never suffer from lack of moisture during the process of root formation, the artificial water supply must not be overdone, indeed, in certain positions the rainfall in winter is sufficient to supply their needs. The condition of the surface soil is a reliable guide, especially if it is kept in a friable state. Bulbs grown in boxes of soil should be covered to a depth of 3ins., and in no case must the top be exposed, as is customary in bowls of fibre that are rooted in the dark.

Some hardy subjects are particularly well suited to our erratic climate and can be relied upon to bloom freely in their appointed season in fair or fowl weather. Strong growing, healthy specimens of Hydrangea paniculata, studded with massive flower trusses, were conspicuous in the early days of October at exposed places on the Firth of Clyde and in Ayrshire, Arran and other districts in the west of Scotland. Fuchsia Riccartoni in bush and hedge forms was truly magnificent, being richly clothed with masses of the well known pendulous red flowers. Escallonia macrantha is another hardy shrub which simply revels in the sea breezes and although it is not so floriferous as F. Riccartoni, compensation is provided by the luxuriance of the glossy evergreen foliage. All the members of this attractive trio are easily propagated by cuttings.

As I write the last rose of summer is still to be seen on the ramblers, which were notable for the extra wealth of bloom over a longer period than is usually permitted in Nature's floral programme. The season, too, has been productive of a generous crop of new wood, which should have immediate attention if the work has not been overtaken. After cutting out damaged or decayed growth, the old wood on which the blossoms of the past summer were borne, the long basal shoots require to be trained on pillars and pergolas, careful tying to the supports being necessary to prevent them being broken or damaged by the gales in winter. Where the growth has become dense and the foliage presents a ragged appearance, it is advisable to strip the tree from the woodwork, as thinning operations are more easily and effectively accomplished while training and tying is made possible on a systematic and simple principle which checks the tendency to form masses of tangled growth. In exposed situations the practice of protecting ramblers in winter by covering them with matting is sometimes followed, but the new wood stands a better chance of ripening when exposed to the influence of air and sunshine. When planting bulbs in the open ground the claims of anemones and ranunculus should not be overlooked, as they belong to that useful group of hardy plants which require little or no care after planting. The former is a most accommodating subject, and when planted at intervals from October until March, a succession of bloom may be had from early spring to midsummer. Anemones luxuriate in a sandy loam deeply dug and enriched with liberal dressings of decayed manure. Of the various types, Fulgens, brilliant scarlet single; St. Brigid, with single and semi-double flowers in lovely shades of colour; and St. Bavo, a sport from fulgens, offer a sufficient choice for the amateur's garden, and the bulbs should be planted with the eyes upwards, 2ins. or 3ins. below the surface level and from 4ins. to 5ins. apart. The French, Persian and Turban ranunculus may be planted in autumn in favoured places where vegetation does not usually suffer from damp in winter, but if these conditions are uncertain it is safer to delay the operation until February or March, as they resent stagnant water at the roots, the presence of which is usually indicated by the foliage turning yellow. The soil best suited for them is a rich, cool, somewhat moist, yet well drained loam. Place the claws downwards in shallow drills, about 6ins. apart and it is an essential condition of culture that the soil covering should not exceed 2ins. in depth.

ST. MUNGO.

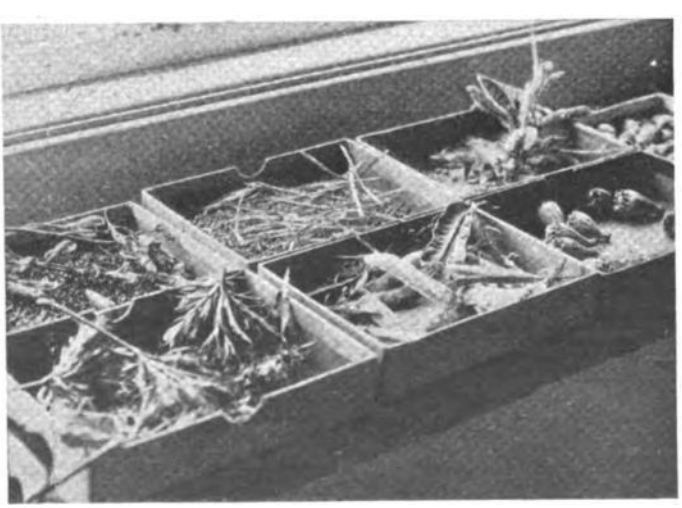
HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful and interesting hint sent in by a reader. Five shillings will be paid for all others published. Payments for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT.

Saving Your Own Seeds.

The time for saving seed having again arrived, the following method for cleaning the seed may be of interest. In the first place, the seed pods, when gathered, should either be dry or thoroughly dried. A method of drying the seed is to put the seed pods in a thin layer in cardboard boxes placed on a window sill or shelf in the greenhouse. They should then be well rubbed between the hands to release the seeds, and the larger pieces of husks picked out by hand. For the actual cleaning process a "Robinson's Seed Sower" can be used, the hole being adjusted to meet the particular needs. For such seeds as wallflowers, candytuft, lupins, poppies, etc., the seed sower should be shaken over a box-lid sharply tilted, when it will be found that the seeds roll to the bottom, while the husks and dust remain behind.—E. K.



SAVE AND CLEAN A FEW OF YOUR OWN SEEDS.
This shows the method of drying them before storing.

Plants for a North Wall.

I would like to draw attention to the merits of Cotoneaster horizontalis, Clematis Jackmanii and the common honeysuckle for growing on walls facing north. They have proved wonderfully effective with me, situated by the side entrance to the house. The cotoneaster heads the procession of bloom, followed by the honeysuckle trained over the doorway; the clematis, planted near the base of the cotoneaster, through which it has threaded its way to the top, being the last to open its blossoms. Both it and the honeysuckle are still blooming — the latter, naturally, somewhat sparsely now —and the cotoneaster is laden with brilliant berries. Thus a striking and lasting display is provided in a position which, from the horticultural standpoint, is commonly devoid of interest.—C. C.

Cleaning the Lawn of Weeds.

Many lawn weeds, such as the buttercup, have swollen turnip-like roots which anchor the plant and make removal difficult. I have found the homely apple-corer the most effective extractor of such roots. Place the "nose" of the corer centrally over the root, and a downward thrust of about an inch will find the root safely in the tube. When the ground is wet and soft, the remainder of the root easily follows. Carry sifted loam mixed with grass seed to fill up the holes.—W. P.

RAISING ROSES & SHRUBS FROM CUTTINGS

This is an important operation that all amateurs should carry out during the next few weeks. In general, firm and ripe wood must be used for these cuttings, which should be made from 9–12ins. long and inserted in a sheltered border of sandy loam outside. It is an excellent way of increasing one's stock of many desirable shrubs and roses.

DURING October and November numerous hardy trees and shrubs can be readily propagated by inserting cuttings of ripened shoots of the current year in borders outside. Select a sheltered position, on a west or north-west border for example, affording some protection from frosts and cold winds in winter. Shelter from the hot mid-day sun in the spring and early summer before some of the cuttings may be well rooted is also important.

Should the soil of the border be naturally rather heavy and damp, work in plenty of coarse grit or sand, and, if available, old mortar and brick rubble will be very beneficial in damp ground. The best average distance apart to insert the cuttings obviously depends to some extent on the kind of plant. As far as possible, however, for ease in keeping the ground free from weeds, and other needful attentions to the cuttings, a uniform distance of 1ft. or 15ins. between the rows and 6ins. to 9ins. apart in the rows, is worth while, the exact distance determined by the size of the cutting and the amount of growth likely to be made by the cutting the first season.

ROSE CUTTINGS INSERTED IN AN OUTSIDE BORDER.

Note the depth to which the cuttings are inserted and the distance apart. One side of the trench should be straight, against which the cuttings are placed; the soil then being filled in.

A Good Average Length for Outdoor Cuttings is 1ft., but the exact length for cuttings from individual kinds of plants depends largely on the growth and nature of the plant. In some cases it will probably be an inch or two less, a very good example being the New Zealand daisy bush, Olearia Haastii. There is no reason why the length of 1ft. should not be exceeded by an inch or two, if suitable healthy wood of medium growth is available. Strong sucker-like growths of most trees and shrubs do not make good cuttings. In the case of the tamarisks, several species of tamarix, it is quite a useful and successful procedure to insert cuttings as much as 2ft. in length in the permanent positions where the plants are to grow. It is a fairly common practice in the case of willows (salix) and poplars (populus) to use cuttings up to 6ft. or even 10ft. or 12ft. in length, and an inch or more in thickness, making the holes with an iron crowbar, or, if the ground is soft, driving the cuttings into the ground with a wooden mallet, as if they were stakes, in the permanent positions where the trees are to grow. This it will be realised is a good means to form a screen, or plantation, in moist ground quickly.

The Depth to Insert Cuttings

in the soil also varies a little. For cuttings up to 1ft. in length, at least half the length should be covered with soil. This practically ensures the roots at the bottom of the cutting being out of the reach of ordinary frosts, and deep enough to be held firmly in the ground. Any disturbance of the surface soil by frosts must be put right by treading as soon as the frost is out of the ground and the surface moderately dry.

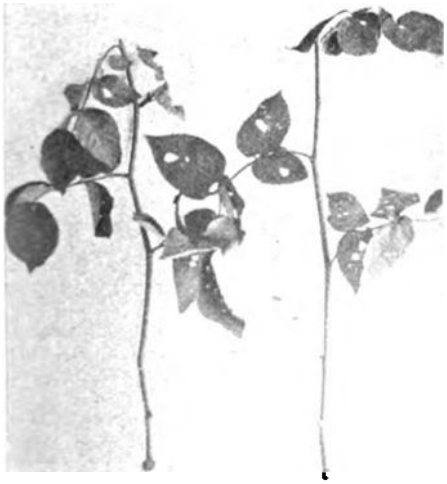
Having prepared the bed of sandy soil, measure out the lines 1ft. to 15ins. apart, placing small stakes at either end. Stretch a line across the border denoting the position of the first row; chop out a trench rather more than 6ins. deep, shake a little sand and leaf-mould along the bottom of the trench. Into this place the base of each cutting at 4ins. to 6ins. or 8ins. apart, according to the growth of the cuttings. Fill in the trench, tread the soil moderately firmly and level the surface. Move the line along to the next pair of stakes and take out a trench as before.

An alternative method is to dig the ground and insert the cuttings in lines as the digging proceeds.

In Making the Cuttings

select well-ripened shoots or growths of the current year. As a rule, other things being equal, the best results are obtained when the cuttings are made with a thin heel of old wood at the base of the cutting. Remove the weak, thin top of the shoot back to firm wood, with a bud in the axil of the leaf to form the top-growing shoot next season. Failing a heel of old wood, cut through the stem just below a leaf or pair of leaves, so that the bottom of the cutting is formed by a node or leaf base.

During severe frost or cold wind in winter



ROSE CUTTINGS PREPARED FOR INSERTION.

Note the length and the nature of the cutting, and that each cutting has a heel.

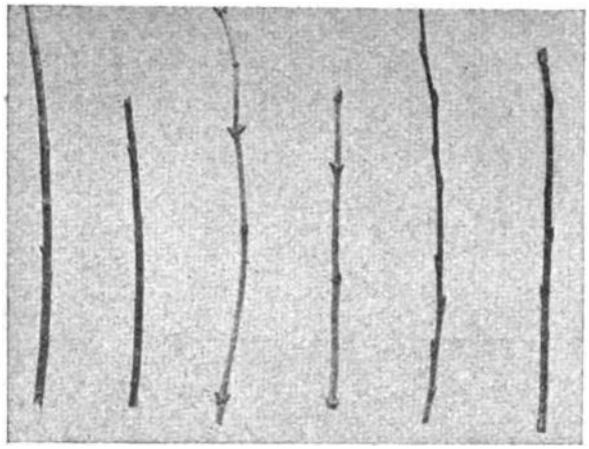
A WELL ROOTED ROSE CUTTING.

Note the mass of fibrous roots which will enable the cutting to establish itself quickly.

Digitized by Google

if the garden is at all exposed it is worth while scattering a few dry leaves or placing pieces of bracken among the cuttings for partial protection.

The question of rubbing out the growing buds on the stems buried in the ground when inserting the cuttings should be considered. In the case of ribes (the flowering currants), the salix, poplars and other subjects required with the single stem, it is desirable to remove the buds. Obviously, however, it would be a mistake to remove the growth buds from the stems of rambler rose cuttings, for these in succeeding years will produce the sucker growths from the base which are such a valuable asset in such sorts as Dorothy Perkins, American Pillar, Excelsa, etc., when most of the old flowering wood is cut out to the base.



From left to right: Unprepared and prepared cuttings of willow, elder and poplar. Note the difference in the cuttings. Each cutting is made below a joint and no ragged edges are left.

In addition to the few subjects already mentioned, the present time is suitable to insert in an open border cuttings of the green and variegated oval-leaved privet, the cherry laurel, the mulberry, the stronger growing hybrid tea roses, the hybrid perpetuals and climbing and rambling varieties; philadelphus, buddleias, forsythias, berberis, diervillas, ivies, cotoneasters, Lonicera nitida, and in the south and west of England the escallonias, veronicas and evergreen euonymus.

Once the cuttings have been inserted, they should be left throughout the winter, perhaps examining them at certain intervals to see how they are progressing. On rooting, they may be lifted and potted up; but, on the whole, it is better to allow them to remain in the open border during the summer, growing steadily all the time and making new growth. A. O.

HOW TO GROW FINE GOOSEBERRIES

Gooseberries are a valuable crop in any garden, and amateurs would be well advised to plant a few bushes this autumn. Hints are given here on the best situation and soil for the growing of gooseberries, while a few reliable cropping varieties are recommended for planting.

AN open situation is essential for the successful cultivation of gooseberries. The soil should be well drained, slightly on the heavy side and retentive of moisture. A border on a north or east wall is an ideal place for planting gooseberry bushes, as it affords protection from wind and also from too much sun.

PLANTING.

The best time to plant is in October or November, but planting may be done at any time after the leaves have fallen until the buds begin to break, weather conditions being suitable. The ground should have been double dug and any manure added should be incorporated in the top 6ins. of the soil, as the gooseberry is a surface-rooting plant. The roots should be spread out at planting, and should not be planted more than 6ins. deep, allowing a clear stem of 6ins. above the surface of the ground. A little well decayed manure may be added to the surface of the ground after planting to cover the root-run. This will act as a protection from frost and help to enrich the soil.

Generally gooseberries are grown as bush trees. Thus if we take our plant one year from the cutting we shall have about three shoots from the buds left on the cutting at the time of planting, and these should be cut back to three or four buds from their base in autumn after the leaves have fallen at transplanting time. Drooping varieties should be cut to an inside bud, upright varieties to an outside bud. In the following year two shoots from each of these cut-back branches should be encouraged to grow. Any others which form should be pinched back in summer and spurred back to one eye in autumn. These shoots, six in number, should be cut back 6-8ins. in autumn, and from these the following year two more shoots should be taken, thus giving us a framework of twelve branches, which is what we require for our bush.

PRUNING.

The gooseberry fruits on the young wood and on spurs, but the finest fruit is produced on well developed annual growths, therefore our object in pruning must be twofold: the encouragement of strong annual shoots and the production of spurs. Summer pruning should be done in midsummer. This consists in pinching weaker growths and growths which are intended to form spurs to four to six leaves as a preparatory step to spurring back in autumn. Growths which are not required for extension or fruiting can be cut right out after fruiting is over. Winter pruning consists in cutting out dead and diseased wood, spurring back summer-pruned laterals to 1in., removing branches which are crowding and restricting growths which are too vigorous while maintaining the shape of the tree.

A RELIABLE EARLY CROPPING VARIETY, KEEPSAKE.

The best time to winter-prune is in November, but it may be done at any time until the buds begin to break.

Gooseberry bushes may be planted 2ft. by 2ft. for the first two years, transplanting at the end of the second year into their permanent quarters at a distance of 5ft. by 5ft.

An annual top-dressing of superphosphate and kainit applied at the rate of 2 oz. and 1 oz. per square yard and forked in in spring will materially assist the trees. If the soil is heavy, basic slag may replace superphosphate, and should be applied in autumn. Some good varieties are:

Red.—May Duke, Lancashire Lad, Whinham's Industry and Warrington.

Green.—Keepsake, Lancer, Careless and Langley Gage.

White.—Whitesmith and White Lion.

Yellow.—Langley Beauty and Sandwich Yellow.

PROPAGATION.

The gooseberry may be propagated by cuttings, layers, suckers or seed, but the usual method is by cuttings taken in autumn or spring of well ripened growths 10ins. to 12ins. long. From these growths all the eyes and spines are removed from the basal 6ins., leaving three to four good buds at the upper end. The cuttings are best taken in early autumn, at pruning time, and inserted in an open space in good rich soil. The distance between the cuttings should be about 6ins., with 1ft. between the rows. They should be planted so that only the upper buds are showing, that is, to a depth of 6-8ins. The cuttings should callus over during the winter, starting into growth in spring, and be ready for transplanting the following autumn. Cuttings may also be taken in spring, buried to the top bud, when they should root and be ready to transplant in autumn 3ins. deep having roots attached.

PESTS AND DISEASES.

Gooseberry Sawfly.—The damage is caused by the caterpillar which eats the foliage. This pest may be controlled by spraying with lead arsenate paste at the rate of ½lb. of paste to 10 gallons of water applied either very early or after the fruits have been picked.

American Gooseberry Mildew.—This disease, which is exceedingly harmful, appears as white patches on the berries, shoots and under sides of the young leaves from April to October. A brown stage occurs subsequently on the shoots and berries and less frequently on the leaves. Control measures are tipping and spraying. Tipping consists in cutting off in autumn all shoots which show the presence of the fungus, *i.e.*, about late August or early September. Spray in spring and summer with lime sulphur at the rate of 1 gallon to 29 gallons of water. At least two or three sprayings should be given during April and May. H.

NOTES ON THE FLOWER GARDEN

Plants for a Shady Garden.

IT is often found that a front garden which has a more or less northerly aspect is difficult to treat and such plants as are employed give indifferent results. In many cases there is no doubt that the cause of the trouble is to be found in the fact that the wrong kind of plants are used. But even when a selection of subjects that do not object to a certain amount of shade has been made, the results are not all that could be wished. In a garden of such a nature it frequently happens that the soil is badly drained, largely owing to the fact that the sun cannot reach the ground and dry it up. When the land is on the heavy side, plenty of old mortar rubble, road grit and wood ashes should be dug in. If the position really seems to be waterlogged, it will be needful to take out the borders to a considerable depth and, at the base, work in a 6in. layer of drainage material. This will involve a certain amount of trouble, but the labour will be amply repaid by the good development of the plants. With the ground in good order there is no reason why the shady garden should not be gay with flowers from early spring to the late fall, providing the position is not actually overhung by trees. Plants which like shade, or at any rate will put up with it, are to be found in the following lists. Spring: Daffodils, snowdrops, scillas, London pride and doronicums. Summer: Foxgloves, calceolarias, Primula japonica, violas, fuchsias and antirrhinums. Autumn: Japanese anemone, Lobelia cardinalis in variety, L. fulgens, Sedum spectabile, tobacco plants and Michaelmas daisies. In a well drained border some of the outdoor chrysanthemums do quite well in a shaded garden.—L. B.

The Ornamental Vines.

OF recent years the value of the hardy ornamental vines has been increasingly realised. These can be grown with great effect on trelliswork, walls or trees, and most of them have extremely handsome foliage which assumes charming tints with the coming of the autumn. Certainly the best known of the ornamental vines is Vitis inconstans, commonly called Ampelopsis Veitchii, which, on account of its self-clinging habit and brilliant autumn tints, is always likely to be popular. Two other kinds, V. quinquefolia and V. q. Engelmanni are sometimes seen, but both these are of much coarser growth than the first-named, although they usually display a fine show of autumn tints. Vigorous sorts of vine which are suitable for growing on pergolas and over large trees and bushes, are numerous. Nearly all of these have handsome foliage, which in many cases assumes fine autumn tinting. The following are to be strongly recommended: VV. armata, amurensis, cinerea, Coignetiæ, flexuosa major, Thunbergii, Thomsoni, orientalis and vinifera purpurea. The last-named is a variety of the common grape, and it is remarkable on account of the wonderful range of colours which are seen in the foliage during the autumn. When planting any of these vines it is important to give them a good start. It is worth while opening out the ground and filling the position, if this should be needful with rich loamy soil. Most of the species vitis will not grow vigorously in poor shallow ground, and in such cases the development is poor. Place the vines a few feet away from the base of trees or shrubs where the soil will be less dry, and then lead the shoots back to the support.—B.

A PLEASANT ROSE GARDEN SCHEME WITH A SUNDIAL AS A CENTRAL FEATURE.

V. COIGNETIÆ, THE MOST HANDSOME AND PROBABLY THE MOST HARDY OF THE VINES.

How to Make the Flower Garden Attractive.

A Suggestion for Next Year.

ENTERPRISING garden lovers will, before now, have formulated their plans in readiness for any additions or alterations they wish to carry out in their flower gardens during the autumn and winter months, and it is the writer's desire that the following notes may be of some assistance in this respect—which, by the way, have been prompted by the fine display of flowers in the accompanying illustration, although this gives but a faint idea of the garden's attraction when the photograph was taken early in July. The chief aim in its lay-out and planting was to have it at its best in July, combined with a good blending of colour, and this, in no small degree, was achieved. The size of the plot illustrated is approximately 120ft., running north and south, by 75ft. east and west, surrounded by a mixed hedge about 12ft. high on the east side, a laurel hedge of similar height on the north, and a yew hedge about 10ft. high on the west side.

The sundial in the centre of the illustration is immediately surrounded with four rose beds, with a grass walk around, and again four other rose beds of the same shape, but, naturally, of much larger dimensions. Beyond these beds is a herbaceous border, delphiniums and verbascums predominating; this border is practically due south. On the extreme right or east point is another herbaceous border, 15ft. wide, two thirds of which is planted with delphiniums, the remaining portion towards the front being filled with bold groups of such subjects as Viola Maggie Mott, Sweet William Pink Beauty, catmint and pink Canterbury bells, which were interplanted with gladioli of various colours for later display. The two narrow borders running from the rose beds and which are 4ft. wide, were planted with bold clumps of catmint, sweet williams (Pink Beauty), pink Canterbury bells, pink and yellow stocks (ten week), pink and yellow antirrhinums (tall section), annual chrysanthemum (Morning Star) and pale yellow viola (Ardwell Gem). On the extreme left of the picture, with the yew hedge as a background, is another border planted with clumps of Lilium candidum alternately with perennial phloxes of various shades of pink. Here again were batches of pink Canterbury bells, Viola Maggie Mott being introduced as an edging.

Where space is available to allow various sections of the flower garden to be at their best during the early summer and autumn

Digitized by Google

months, is a method well worth adopting, and the numerous subjects that are available in these days renders it a fairly easy matter to secure a profuse and attractively blended colour display throughout the summer and autumn months.—W. F. FAIRMAN.

Tubers in the Flower Garden.

Storing Them for Winter.

CERTAIN tubers and bulbs after their flowering season in the garden are best, for safety's sake, lifted from the soil and put away until planting time comes round again. They are galtonias (Hyacinthus candicans), begonias and gladioli. About the first, a difference of opinion exists as to the need for lifting the bulbs at all, many holding to the belief that they are perfectly hardy and can be left where they were first planted without any fear. Such statements need qualifying. In warm localities, as in the south of England, or in places where the soil is naturally sandy, no one may have any apprehension about leaving them in the soil for the winter; but in damp, low-lying districts there is no guarantee of survival. One notices now and again advice given about planting the bulbs "any time between November and March." The latter month is less risky, and, after all, bulbs then are very little behind in their flowering in earlier planted ones in safe quarters. In the circumstances, I have found the wisest course to follow is to lift the bulbs in October, lay them on their sides in a cool dry shed until the foliage has sufficiently died away to be pulled. The same rule governs gladioli, although in their case I occasionally find corms coming through in spring which have escaped me at lifting time. I venture to say, in view of the great interest now being taken in this charming flower, that few growers would deliberately allow their corms to remain in the ground for the winter and take their chance, particularly some of the choice sorts. A mistake which is sometimes made in lifting gladioli and bunching them together is to hang them up by the foliage. This, I have always contended, is a mistake, as more than once, when lifting has been done and the leaves are more or less green, the sap has drained into the corms, causing them to rot off. If the treatment is reversed, and the corms are above the foliage, it will be found that the moisture will drain from them without injury or loss. With regard to begonias which may have been bedded out, the earlier in October the tubers are lifted from the ground or window boxes the better, as they will not stand much, if any, frost without risk. The soil should be carefully removed from them and they should then be spread out on sheets of paper, or on a greenhouse shelf, but not in direct line with the sun, until the foliage can be taken away.

Winter Storage.

A cool and dry shed, away from frost, I find the best, and the corms and tubers can be put in boxes in coconut fibre or sand. The latter will be found as useful as any material. It is well, however, to examine them occasionally during the winter, and remove any that show signs of decay, as, packed together—as one is obliged to do sometimes—one tuber affected will soon contaminate others.—W. L. L.

WHAT OUR READERS SAY

WANTED: A NEW CLASSIFICATION OF DAHLIAS.

SIR,—Among dahlia-lovers there is a growing body of opinion that a new classification of this popular flower is overdue. New forms and variations of old forms are being evolved, and schedule makers and catalogue compilers find themselves more puzzled every year in their endeavour to make the various classes inclusive and exclusive in their definition. The renaming of the miniature peony-flowering class as "charm" dahlias seemed a happy inspiration, but it was not long before confusion was introduced by some growers putting the small-flowered decoratives into the "charm" class, while other growers adhered to the old separate class arrangements.

That beautiful flower, "Oriole," which figured for so many years as a star dahlia, is now found in most catalogues in the charm class. The great difficulty in placing it correctly must be recognised, for, while it is different from the other star dahlias, it is sufficiently "starry" to look somewhat out of place among the charms. The cactus pompon or pompon cactus is another fairly modern development which must be taken into account. The collarettes, the first examples of which were all of a similar build, are beginning to show divergencies which may eventually lead to a subdivision of the class. The most recent complications are the appearance of (*a*) a clematis-flowered dahlia, Ada Finch, and (*b*) decorative cactus or cactus-decorative flowers—for example, Mrs. Krelage. Where are these to go? It seems to me at present that they should find their home among the decoratives, although it must be admitted that in the case of the cactus-decoratives there is enough of the cactus type in their build to justify inclusion in the cactus class, unless it be felt that they are deficient in some of the spideriness which characterises the cactus dahlia.

I have made two attempts to frame a new classification. The first (A) meets, I think, most, if not all, of present-day requirements, and would probably form an elastic framework capable of development according to the evolution of the future. It is logical in plan, although it has two disadvantages, *viz.*, abolishing two of the old familiar names and coining one new name. Some of the old class-names, *e.g.*, Show and Fancy, have lost their meaning and applicability and are, indeed, definitely misleading; and, further, there is no obvious reason for maintaining the distinction between Show and Fancy. "Rosette" is the best descriptive name I have been able to think of for a class which should include the flowers having the form of the Shows, Fancies and Pompons. After all, a brand-new name sometimes meets with approval by the *cognoscenti* and acceptance by the multitude; such names as "Pernetiana" roses and "Cynthella" hyacinths are new names which have come to stay.

CLASSIFICATION A.

Class or Division.	*Present Class or Variety Name.*
1. Single:	
(*a*) Tall ..	.. Single.
(*b*) Dwarf ..	.. Mignon.
2. Star:	
(*a*) Type ..	.. Star.
(*b*) Decorative	.. "Oriole."
3. Collarette ..	.. Collarette.
4. Cactus:	
(*a*) Large-flowered	.. Cactus.
(*b*) Miniature	.. Pompon cactus.
5. Decorative:	
(*a*) Large-flowered	.. Giant decorative.
(*b*) Miniature	.. Camellia-flowered or small decorative (part of Charm class) and anemone-flowered.
(*c*) Cactus-flowered	.. Decorative cactus or cactus-decorative.
(*d*) Clematis-flowered	Clematis-flowered.
6. Peony-flowered:	
(*a*) Large ..	.. Peony-flowered
(*b*) Miniature	.. Miniature peony-flowered (part of Charm class).
7. Rosette:	
(*a*) Large-flowered	.. Show and Fancy.
(*b*) Pompon ..	.. Pompon.

There are, of course, several debatable points in this classification, but it might form a basis for discussion.

The alternative classification (B) is an attempt to do something towards obviating the anomalies which have arisen without making more alterations in the present system than are absolutely necessary. The amateur gardener is just beginning to know what Mignon dahlias are, although Coltness Gem is, perhaps, the extent of his knowledge, and it may be argued that it is unwise to ask him to accept an altered nomenclature, but alterations must sometimes be made, and we must not be hide-bound. The weakness of Classification B is that it would not dispose of all the anomalies of the present haphazard and muddled system.

CLASSIFICATION B.

Class or Division.	*Present Class or Variety Name.*
1. Single:	
(*a*) Tall ..	.. Single.
(*b*) Dwarf ..	.. Mignon.
2. Star	.. Star.
3. Collarette ..	.. Collarette.
4. Cactus	.. Cactus.
5. Decorative:	
(*a*) Giant ..	.. Decorative.
(*b*) Cactus ..	.. Decorative cactus.
6. Peony-flowered	.. Peony-flowered.
7. Charm:	
(*a*) Peony-flowered	.. Charm.
(*b*) Camellia-flowered	Charm.
(*c*) Star-flowered	.. "Oriole."
(*d*) Clematis-flowered	Clematis-flowered
8. Rosette:	
(*a*) Large-flowered	.. Show and Fancy.
(*b*) Pompon ..	.. Pompon.

In conclusion, I suggest that the Royal Horticultural Society and the Dahlia Society should appoint a joint sub-committee to consider this matter and submit recommendations at an early date.

F. WYNN HELLINGS.

SILVER LEAF DISEASE ON PLUMS.

SIR,—I have been much troubled the last few years with silver-leaf disease on my plum trees, and have had to cut down several of them altogether. Last year I had again to cut out several branches of a Coe's Golden Drop which were affected, when I saw in THE GARDEN (August 28th, 1926) a suggested remedy, by spraying the trees with permanganate of potash, so I thought I would give it a trial.

I sprayed the trees (they are on a wall) several times during the winter and early spring, before the leaves came out, with a strong solution of the permanganate, and I am glad to say that this year there has not been a trace of the disease on any of the trees. It certainly seems to be a very efficient remedy, and I should strongly advise any of your readers who may be troubled with the disease to give it a trial.

I intend to give my trees another good spraying this coming winter, and will let you know the result.—G. ANSDELL, *Dinton, Wilts.*

FLOWERS IN THE ORCHARD.

SIR,—Now that the posts are bringing us the attractive catalogues of the bulb growers, it is well worth while to give the orchard a place in our purchase plans. Nearly all the catalogues include cheap bulb collections for naturalising in grass. It is possible to buy several hundred bulbs for a few shillings—snowdrops, the varieties of crocus, chionodoxa, scillas, aconite, grape hyacinths and daffodils—all of which will do well in the orchard turf.

All that is necessary is to make a hole about 3ins. deep with a narrow trowel, drop in a little coarse sand, and put in the bulb. They will flower profusely and rapidly increase into lovely drifts of colour.

Another simple plan for beautifying the orchard in early spring is to remove the turf round each tree, pile up a small bank of soil round it, and plant the strong-growing aubrietias, such as "Prichard's A.1," or "Dr. Mules." They do well in the slight shade and soon make brilliant violet and purple mounds at the foot of the trees. Some of the early mossy saxifrages, such as S. Bathoniensis and S. muscoides, and London Pride, may be used in the same way.

Dwarf irises are easily grown in orchard soil; the early anemones, apennina, blanda and sylvestris, find it as congenial as their alpine woodland pastures and the blue hepatica revels in its shady loam and leaf mould. And, of course, primroses, violets and forget-me-nots cannot be too freely welcomed in the orchard.—G. H., *Northampton*.

MODERN DELPHINIUMS.

SIR,—*Re* "G. A. P.'s" notes of the Wrexham delphiniums, "the trade" has always been looking for unsual colours in purchasing, and unless "the blues" have pips 3ins. across they will not purchase. They are looking at the individual flower and not the colour scheme. I enclose two illustrations that may be of interest to your readers as modern productions in the world of delphiniums. No. 38 is a Cadet blue with the smallest shade of light mauve edging. The illustration is of a bed of this plant which was divided up in March last. No. 47 is manganese violet with cornflower blue shading.—WATKIN SAMUEL, *Wrexham*.

A MODERN DELPHINUM PRODUCTION OF MANGANESE VIOLET COLOURING.

PLANTING OUT CABBAGES.

SIR,—I have read with much interest "G. W.'s" remarks on "Planting out Cabbages" (page 628), and while doing so it struck me that some of the readers of THE GARDEN might like to hear of a less troublesome and probably more successful method.

A good many people plant cabbages farther apart than is necessary, especially early kinds. A square foot is quite enough for Harbinger and April. Where a brisk demand exists for cabbages they will be cut as fast as they become fit for use, and so anyone that seems inclined to grow a little larger than the others will have room to do so. Fifteen inches apart each way is quite enough space for the Enfield Market variety, for no one cares for a large, hard-hearted cabbage—at least, not in a private garden. Plant in drills, and firm the plants well in the ground; I have not planted on freshly dug land for many years. I plant cabbages following the onions, and therefore the land is rich enough for them. A dressing of soot is, however, often given, hoeing it in deeply; the drills are drawn with the corner of the hoe, and the plants set out in the drills at varying distances, according to kinds, but mostly 12ins. to 15ins. apart.—JAMES A. PAICE, *Middlesex*.

DISTANCES FOR FRUIT TREE PLANTING.

SIR,—I see in your issue of September 24th, page 630, you give the distances at which various fruit trees should be planted.

I think those for bush, half standard and standard trees are not nearly sufficient, at least for the strong growing varieties. As planting too close is a mistake made by most amateurs, I should like to relate my own experiences.

About twenty years ago I planted about half an acre with Bramley and Newton Wonder bushes on Paradise at 12ft., as advised in the catalogues of the nurserymen who supplied the trees, but I soon found out they were too close. So all were taken up and replanted at 18ft., following the advice given in Seabrooke's "Practical Fruit Growing," but the trees are now almost touching and it is impossible to get round them properly for spraying, etc.

If I had my planting to do again I would space strong growing varieties, such as Bramley, Newton Wonder, Blenheim Orange, etc., at not less than 24ft., and standards on crab at 30ft. at least. Many people generally plant their trees too thickly, leading as you say to disastrous results, for which there is no remedy, as the trees are then much too large to transplant.—EDWARD T. BROWN, *Brigg*.

OMPHALODES LUCILÆ.

SIR,—In reply to Mr. Arnott's letter, Omphalodes Lucilæ grows successfully with me in Oxfordshire in ordinary limestone moraine mixture—two-thirds chips to one-third gritty soil. If moisture can be given underground so much the better, and under these conditions O. Lucilæ thrives in a very hot exposure of the rock garden. If underground watering is not possible, the plant must be given a certain amount of shade from rocks. Being a southern crevice-lover, its most characteristic position would be in a chink of a sunny wall, where its roots could wander far in and find abundant moisture. This last, again, provides a difficulty; it may, perhaps, be overcome, as Farrer suggested, by sinking a pipe or flower pot down into the wall from above and periodically filling it with water.

A NEW BLUE DELPHINIUM, EDGED WITH LIGHT MAUVE.

Once get O. Lucilæ to grow, and there will be no trouble about flowering. My moraine plant has flowered this year from the end of June to the end of August, without stopping, and is even now making another effort! I think one should consider the plant's provenance and cover it over in winter with a sheet of glass to keep off the worst of the wet; this may not be necessary, but is sure to be appreciated.

Finally, O. Lucilæ comes quite freely from the seed which it usually sets without trouble, though the glaucousness of the leaves, which is so attractive, is apt to vary.—R. BEVAN, *Henley-on-Thames*.

A FINE EASILY-GROWN CACTUS FOR THE GREENHOUSE.

Phyllocactus Dr. Bois Duval.

SIR,—I have had a large plant of this fine cactus for some years. I moved it from Cottingham, East Yorks, two years ago, and it is now growing in a cold greenhouse in Surrey. This summer it had between fifty and sixty flowers, which are of a brilliant red—very much the colour of a red currant, with blue shading inside and cream-coloured stamens. The flowers are sweet-scented the evening they open, but have lost their fragrance by the following day. They last about three days on the plant or when cut for the house. This cactus has flowered regularly every year since I have had it. The flowers are about 8ins. across. It is very easily grown. I give little or no water during the winter—beginning to water in March, when growth begins, and continuing to about the end of September, when it is allowed to become dry again. The plant must be exposed to full sun throughout the year. It is syringed daily while the buds are forming, as they and the young shoots are liable to damage from greenfly. The plant will not stand actual frost, and in its present quarters is protected in winter by means of an oil lamp. The plant in its pot stands about 7ft. high.—RUTH BICKERSTETH, *Surrey*.

FRUIT AND KITCHEN GARDEN

Fruit Picking and Storing.

APPLES and pears which are of the "keeping" kind should be left on the tree as long as possible. There is no harm, in most cases, in allowing the fruit to remain until early November, unless it begins to drop of its own accord. If fruit is gathered before it is fully matured, it is likely to shrivel when stored. Apples are fit for picking when, on cutting open a sample or two, it is found that the pips are dark brown in colour. Test the fitness of a pear for picking in this way: Hold the branch in one hand and then raise the pear gently upwards with the other. If the stalk parts from the branch readily the fruit is fit to pick. As the smallest bruise will destroy the keeping qualities of apples and pears, great care should be exercised when picking and storing. Never throw the fruit into a basket or dump it in a pile on the floor; keep all windfalls, however sound these may seem to be, separate from the gathered fruit. All fruit should be looked over and graded into sizes—large, medium and small—for storing. As a rule, the small fruits keep the longest, and, in using, the larger specimens should be selected first. Never store any fruit save that which is absolutely sound. Many kinds of apples "sweat" badly after picking, and it is well to spread these out in a single layer, if possible, with a small space between each fruit, for quite a week before any storing or packing is attempted. Fruit keeps best in a place that is rather dimly lit. The average cellar makes quite a good storehouse; or satisfactory conditions can usually be found in some attic.—L. B.

Loganberries and Similar Hybrids.

THE appearance of a loganberry during September strikes terror into the hearts of many, otherwise it would be one of the main small fruits in every garden. The berries are, of course, primarily for culinary purposes; it is an enormous cropper and bears a heavy weight of berries per bush. Its one drawback is noticeable when the old stems have to be cut out about this time; still, good gloves discount its terrors. The Laxtonberry is a rounder, bigger-seeded fruit, but it has not done so well this year owing to lack of bees and such-like insects; this variety is self-sterile and only succeeds when near raspberries and similar fruits. When things go all right it is a wonderful fruiter and heavy crops are carried from July until October. The fruits are sweeter than the loganberries and not unlike raspberries. The Lowberry is a black loganberry of delicious flavour; it always grows vigorously but has failed to fruit this year. The King's Acre berry is, to all appearance, a kind of bramble; the fruits ripen earlier, however, and the flavour is fine. The Newberry comes nearer to the raspberry than any of the above; the fruits are large and excellent dessert berries. The Himalayan berry is a very early and very fine bramble which ought to be grown by everyone who likes that delightful autumn berry.—CLYDESDALE.

How to Grow Good Bush Fruit.

IN most gardens there is a border which can be devoted to the cultivation of these fruits solely. The amateur wishes to grow the finest fruits of each kind; it may be for home consumption in the form of dessert or for exhibition. The best can rarely be grown in an open quarter of the garden with just ordinary attention bestowed upon them most of the year and very special attention when the fruits are nearing maturity. Begin now by selecting a site—one open to the south-east, south or south-west. Of course, the bushes must be protected by wire netting or tarred nets in due course; so the necessary standards and cross-bars should be selected and prepared during the winter months. The current work consists of getting out the old soil to a depth of 18ins. and wheeling it to some near-by border where it can be usefully utilised; but, before any soil is taken to such border, reserve the top 6ins. for use again in the making-up of the fruit border.

Having taken out the soil, fork up the subsoil deeply, but leave it below; then begin to refill the hole made with good fibrous turves, leaf-soil, manure, wood ashes and bone-meal.

The work is done as follows: Having placed chopped fibrous turves in the bottom, put on them a thin coating of old lime rubble, or one of dry, unslacked lime; then add a layer of rotted manure and chopped turves, and, finally, fill up the space with ordinary garden soil. Plant the fruit trees in short, rows and provide stakes or wires as supports. Plant when the new soil has settled down; do not overcrowd. To protect the fruits from birds, fix standards nearly 6ft. high and cross-bars to bear up the nets. Next to the ground fix fine-meshed wire netting, the tarred netting just falling below the top edge.

Blanching Endive.

MANY lettuce plants have suffered severely from the recent incessant rains, and slugs. The leaves have been badly eaten by the latter, and the constant damp has resulted in many seared leaves. Endive plants have not suffered in any way, and where there are, nice batches of them some should be blanched. An expert cultivator will lift and blanch the plants under glass, mainly in frames. But the inexperienced may succeed better if the plants are blanched in the open border. Avoid placing empty inverted flower-pots over the plants, or tiles and slates pressed on the hearts, or the plants will rot. Lay down a few branching sticks on some plants and on the sticks some mats. A current of air will pass under the covering material, and the darkness will ensure blanching and cleanliness of leaves.

Another simple and safe way is to gather the outer leaves to form a loose hood over the centre or heart of the plant and tie them in position. The leaves must be quite dry when they are so tied.—G. G.

Present Treatment of Soils.

IF cultivators thoroughly understood how soils should be treated at this season of the year, much labour might be saved and with a great deal of benefit to future crops. I know that some persons work by rule of thumb, as it were; they dig or trench the soil and they crop it just when certain dates come. Heavy soils should not be dug while in a sodden condition; if they are, the lumps remain like those in a clay heap in a brickyard. True, ridging may be done while the soil is wet, as the lumps will be subjected to air and frosts and be sweetened and pulverised. In the case of ordinary digging, the surface only becomes pulverised, generally it pans down in a sodden condition, preventing air and water entering. In the spring the soil immediately below the surface is wet and sticky and does not "work" kindly throughout the whole summer. Leave such wet soil until it has dried well, then dig or trench it, and be sure that the top portion be left as lumpy as possible. A dressing of dry lime, left on all winter, will do a lot of good. I have found it advisable to leave undug medium heavy loam until the early part of spring where it is very wet, rather than dig it in the early part of the winter. When dry, in March, the soil is dug, prepared and cropped and the vegetables thrive well.—HANTS.

Seedsmen by *Appointment*

RENOVATE *your* TURF *at* ONCE

To ensure your Lawns being in perfect condition for next season, a certain amount of attention should be given at this period of the year, and a little care and trouble devoted now will be repaid handsomely during the Spring and Summer months.

Carters Tested Grass Seeds, Fertilisers and Worm Killer are used exclusively by the All-England Lawn Tennis and Croquet Club, Wimbledon, Queen's Club, etc., etc.

CARTERS TESTED GRASS SEEDS
for light, medium and heavy soils.
Price per lb. 2/9, 14 lbs. 35/- per bushel, 28 lbs. 67/6

GRASS FERTILISERS
Carters Complete Grass Fertiliser No. 1 contains all that is necessary for the growth of fine grasses.
7lb. 3/-, 14lb. 4/6, 28lb. 8/-, 1 cwt. 25/-

WORMS
Carters Worm Killer is absolutely infallible for killing worms.
7lb. 3/6, 14lb. 5/-, 28lb. 8/-, 1 cwt. 19/6

WEEDS
"Carterite" is a preparation manufactured by us for the total extermination of daisies and other shallow-rooted weeds.
7lb. 3/-, 14lb. 4/3, 28lb. 8/-, 112lb. 27/6

All prices quoted are Carriage Paid.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2916 Saturday, October 22nd, 1927 Price TWOPENCE

THIS ILLUSTRATION WILL GIVE YOU SOME IDEA OF THE VARIETY OF COLOURS YOU WILL FIND IN ST. BRIGID ANEMONES.

REAMSBOTTOM & CO'S Latest Improved Gold Medal Strain is far superior in shape of blooms, exquisite variety of colours, length and stiffness of stems; with their large paeony-like blooms, they are the finest in the world, and range in colour from the most glorious scarlet to the deepest blue, embracing the most delicate shades of pink, salmon, mauve, lilac and white. PLANT NOW.

NAMED VARIETIES (First Year Offered.)

WINDSOR PINK (new).—A most exquisite shade of salmon. 10 6 doz., 80 - per 100.
DOROTHE PLUNKET (NEW).—Rich Blue, great v.admired. 7 6 doz., 55 - per 100.
MISS GLADYS COOPER (NEW).—An exquisite Burmese pink. 7 6 doz., 56 - per 100.
LADY KENYON (NEW).—A pretty mauve lilac shade, vigorous. 7 6 doz., 56 - per 100.
SEA SHELL (NEW).—White with pinky shading. 8 6 per doz., 65 - per 100.
VICTORY.—Brilliant scarlet. 9 - doz., 70 - per 100.
PEARL.—Very pretty pink and always admired. 7 6 doz., 56 - 100.
CRIMSON KING.—Rich glowing crimson. 9 - doz., 70 - per 100.

GOLD MEDAL MIXTURE, all colours, very fine, strongly recommended. 12 bulbs for 3 -; 25 for 5 6; 50 for 9 6; 100 for 18 -; 200 for £1 14 -; 1,000 for £8.
All Post Free for Cash, with Cultural Directions and Guarantee of Success.
Coloured Illustrated Catalogue of other Anemones, Hardy Plants, etc., for present planting, Post Free on Application.

VOL. XCI.—No. 2916. OCTOBER 22, 1927. PRICE TWOPENCE.

DIVIDING PERENNIAL PLANTS

FROM mid-October to mid-November, provided the weather is open and the soil in a favourable condition, is an excellent time to lift and divide all herbaceous perennials. The sooner the division and replanting are done the better, as the divided portions have then a better opportunity to become quickly established in their new positions before hard wintry weather sets in. Early replanting means that the plants have the chance to make new roots before growth ceases for the year. When dividing, lift the crown of the plant carefully and break off the new crowns that have formed around the old central one. The old central crown can be discarded, as it will never make a good plant next year, and the outer portions can then be replanted separately. Surgical division is necessary with most herbaceous plants as otherwise they become straggly and get out of hand. Flowering is interfered with, as the plant chokes itself through want of space. Divided plants generally show stronger flower-stems and larger and more flowers per plant than those which are left untended. Moreover, it is an economical way of increasing one's stock of any plant, particularly in the case of a desirable variety which it is wished to increase and to keep true to colour. It is not a difficult operation to carry out. Lift the old plants carefully with a fork or spade and pull the portions away with a small hand fork, replanting each firmly in good soil. Do not plant too deep. Deep planting is responsible in many instances for the failure of plants to do well. With peonies, for example, the top buds should not be more than 2ins. or 3ins. below the soil surface. If they are planted deeper they do not bloom well. All amateurs should make a point of attending to the division of all herbaceous plants that require splitting up during the present weeks.

This Week's Work

For Gardens in the South and Midlands.

Lift, dry and store begonias and gladioli.

Take cuttings of gooseberries, currants and loganberries.

Prepare ground for planting roses and fruit trees.

Finish grease-banding fruit trees.

Remake lily of the valley beds, and pot up some crowns for forcing.

Clear beds for spring bedding, and plant out wallflowers, polyanthus, forget-me-nots, etc.

Examine bunches of grapes still hanging on the vines and remove all decaying berries.

Plant St. Brigid anemones.

Cut back overgrown plants in the rock garden.

A Fine Autumn-Flowering Plant.

MESSRS. BARR'S of King Street, Covent Garden have sent us a few spikes of the decorative Schizostylis Mrs. Hegarty to brighten the editorial table, and as this is a plant which is not at all well known among garden lovers, it seems worth while calling attention to its undoubted merits. It is a remarkably fine plant for cut-flower indoor decoration in late autumn, and of the many varieties the pink Mrs. Hegarty is the best for the purpose. If the spikes are cut in the bud state and placed in water in a warm room, they gradually open into the most charming cup or saucer shaped flowers with long pointed petals of a rich shade of pink. The blooms continue to open up the spike in succession, like the gladiolus, and in this way they remain decorative for even two or three weeks if the water is kept fresh. They are not difficult plants to grow in the garden. They are quite hardy, and their principal requirements are an adequate supply of moisture and liberal treatment. The soil should be liberally dressed with old manure and plenty of water given during dry weather. This little trouble will be amply repaid during October when they produce their mass of blossom. They are also well adapted for growing as pot plants in the cool greenhouse or conservatory. If grown as such, it is a good plan to give a little weak manure water once a week as the flowering stage is approached. Once amateurs give the plant a trial they will continue to grow it, as unquestionably it is a plant with a dual purpose. Its time of flowering, its decorative value in the garden and indoors, and its attractive pink blossoms should commend it to all. All amateurs should keep a look out for it at the autumn flower shows, where it is certain to appear in several exhibits. Those who do not know the plant should most certainly make a point of seeing it at the present time, and so discover its merits for themselves.

The Jones-Bateman Cup.

THE Secretary of the Royal Horticultural Society desires to remind those who intend to compete for the Jones-Bateman Cup that accounts of their researches should reach him at the offices of the Society, Vincent Square, Westminster, S.W.1, by October 31st. This cup, which was presented to the Royal Horticultural Society in 1920 by Miss L. Jones-Bateman, is a valuable silver-gilt replica of the Warwick Vase. It is offered triennially for researches in the growing of hardy fruits, figs, grapes and peaches, in the open and under glass. Any account of research submitted by a competitor must deal with work carried out by himself in Great Britain or Ireland, mainly during the last five years. The cup will be held for three years by the successful competitor, who must give a bond for its safe return. A successful competitor is eligible to compete on the next or any subsequent occasion when the cup is offered for award. When the cup is relinquished the holder will receive a Hogg Medal specially struck in gold. The accounts of the competitor's work will be submitted to three assessors (two appointed by the Royal Horticultural Society and one by the National Farmers' Union), who will report to the Council of the Society.

This Week's Work

For Gardens in Scotland and the North.

Transplant fruit trees and bushes that are defoliated.

Prepare beds for new roses.

Give celery a final earthing-up on a dry day.

Transfer schizanthus seedlings from boxes to thumb pots.

Transplant spring cabbages remaining in nursery bed.

Dust gooseberry and red currant bushes with lime.

Begin the planting of tulips out of doors.

Divide and replant herbaceous peonies.

Box seed potatoes whenever they are procurable.

Continue bulb planting in beds and borders.

Digitized by Google

ANEMONES FOR YOUR SPRING GARDEN

The windflowers are primarily plants for the amateur. They are easy to grow, flower plentifully and freely over a long period and provide a most welcome colour display during the spring months. They show as great a variety in the colour of their blooms as they do in their form and habit. As this article indicates, species and varieties can be had for all purposes.

IF we consider the whole of the genus anemone we find a wide range of plants, and one of the loveliest sights in early spring is the wood anemone or A. nemorosa, which can be seen in countless thousands in many plantations. At the other end of the group we have the forms of A. japonica, so useful for the herbaceous border, and between the twain will be found a host of lovely species, varieties and hybrids which adorn our gardens onwards from early spring. It is some of these we shall consider in the present article, and the first to call for notice is the St. Brigid or Irish anemones, so admirably displayed on the front cover of the present issue. When writing of the St. Brigid anemones the firm of Messrs. Reamsbottom naturally come to the fore, because they have done so much to improve and popularise this beautiful flower.

The best St. Brigid anemones are characterised by two important factors, *viz.*, their sturdy constitution and exquisite range of colours. The flowers are large, borne on strong, erect stems, semi-double, with fine broad petals, thus forming a kind of shallow cup with a handsome blue-black central boss. If cut before the flowers are fully developed, they are excellent for decorative purposes. The later forms of St. Brigid anemones are a great improvement on the older kinds, and the range of colours and colour combinations are almost endless, yet the rich and varied hues blend in a most harmonious way and are always pleasing to the eye.

Another noteworthy section is the Caen, poppy, or giant French anemones, of which there are both single and double flowered varieties. A good mixture is hard to beat for the small garden, but where there is space and beds to fill some of the named forms will be found useful. Among them will be found vivid vermilion, bright rose pink, blue, scarlet, white, etc., while a mixed strain would contain the most brilliant and varied colours. In the Caen or poppy anemones we have a delightful class, which, like the St. Brigid, are sure to give satisfaction to all flower lovers.

In the section known as St. Bavo we have a beautiful race or strain of A. fulgens. Although the strain received an award of merit from the Royal Horticultural Society on April 27th, 1920, when exhibited by Mr. C. van Tubergen, Haarlem, Holland, they do not appear to have found their way into British catalogues generally. I hear, however, that Messrs. Barr offer them in their current catalogue on very reasonable terms. All those who appreciate the gorgeous A. fulgens with its graceful poise and habit will heartily welcome the St. Bavo group, which only differ in colour from the type. Last year I grew a small quantity, and among them I had shades of rose, salmon, red, rosy lilac, magenta and blush, each flower with a silvery white centre. They were free-flowering, and attained a height of about 9ins. The tubers were planted in November, and were in bloom from early March to nearly the end of April. When the foliage had died off half were lifted and the remainder left in the ground, so it will be interesting to watch results next spring. It is a handsome and showy strain, with a great variety of colour, and should certainly be tried by all who enjoy the starry windflowers.

In A. fulgens we have one of the most brilliant of windflowers, the blooms being single and a rich dazzling scarlet with a blue-black central boss. It is not so robust as the sections already noted, but if given a well drained rich soil and left undisturbed it usually produces a full crop of flowers. With new tubers I usually plant from January to March. Like all anemones, the foliage is both light and elegant, and the plants are always pleasing from the appearance of the first leaf till the roots die off.

There are also many anemones suitable for half-shady positions and for naturalising in the woodland where it is not too dense. For instance, the different forms of A. nemorosa, especially the soft pale blue Robinsoniana; A. Hepatica, the well known Hepatica of gardens, of which there are numerous forms; and the white A. sylvestris, or snowdrop anemone, its delicate drooping flowers being borne on stems 1½ft. high. A. apennina, the blue wood anemone, is also a delightful plant, and another excellent windflower is A. narcissiflora with a bunch of flowers like apple blossom. It is of easy culture and worthy of a trial. The pasque flower, or A. Pulsatilla, is one of the earliest spring blossoms, usually violet in colour, and there is also a white variety.

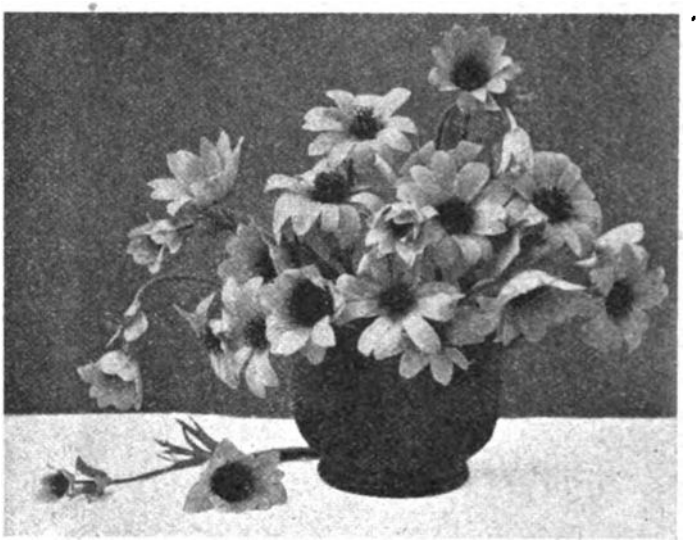
ONE OF THE FINEST ANEMONES: THE CLEAR-CUT STARS OF A. APENNINA. A PLANT FOR HALF SHADE.

Suitable Sites for Anemones.

Many anemones are woodland plants, but those quoted above enjoy plenty of sunshine. If, however, they can be partially shaded about midday it will be an advantage. Beds filled with anemones are very effective, blocks in the herbaceous border will brighten things up in early spring, while there is often a narrow border in the kitchen garden which could be filled with these charming subjects, especially where cut flower is in demand. Small colonies on the rock garden are advised, and A. fulgens is well adapted for this purpose. Some may prefer them as an edging, but, personally, I think the best effect is obtained by massing in a bed or border. These plants enjoy a loamy or sandy loam soil where it is well drained, but a heavy rooting medium can be rendered suitable by the addition of sand and a little old lime rubble; in fact, anemones rather appreciate a proportion of lime in the ground. They also enjoy a rich soil—and well decayed cow manure several inches below the tubers, chopped up turf fibre or hop manure should be added when the bed is prepared. The soil must be made fairly firm before planting, and an effort should be made to set the tubers at a uniform depth of about 2ins. or 3ins. The tubers are somewhat irregular in shape and it is often a puzzle to know which is the growing point. When in doubt lay them sideways and they will grow equally

Digitized by Google

as well. Some growers plant the tubers in lines 8ins. or 10ins. apart, a system recommended if they are cultivated for cut flower only, but for beds a more irregular method is chosen, and a distance of 4ins. to 6ins. is allowed. By planting at intervals a supply of bloom can be kept up for several months. A batch can be put out in October and November to furnish flowers in early spring or about April. The next lot should be planted in January and February for a June display, and if space and tubers are available, planting may continue till May, whereby a succession will be kept up during the summer months. When the operation is completed make the soil fairly firm with the back of a spade, but not hard. The plants should be kept free from weeds, either by hand weeding or a light hoeing. There will be no necessity to disturb them for several years, until a fresh site is required through exhaustion of the soil. Much, however, can be done by an annual mulching of screened well decayed manure or leaf-mould just before growth begins, while liquid cow manure is also a good stimulant during the period of activity.



THE BRILLIANTLY COLOURED ANEMONE FULGENS.
An attractive plant for table decoration as well as for the garden.

Anemones from Seeds.

It is not generally known how easily these useful plants are raised from seeds, and if the seeds are obtained from a reliable source, some exquisite forms will reveal themselves at flowering-time, but it should be borne in mind that some of the seedlings will produce flowers not worth retaining. These should be dug up directly they bloom and destroyed. If it is thought advisable to use home seeds, they should be only collected from flowers of good form and colour, otherwise dirty whites and washy blues will predominate. Choose a sunny spot for the seed bed, and sow the seeds thinly in late spring or directly it is ripe, and only just cover with fine soil. It is usual to shade the bed for a week or two until the seedlings appear, when they are gradually inured to full sunlight. Keep the soil moist throughout the summer, and the seedlings can be left in the seed bed till they flower. Mark or label the best varieties, and remove them if required to another station about October. Flowering tubers, however, can always be procured at a very moderate cost, and unless one has space and time at one's disposal, it is better to rely on tubers than attempt to raise a stock of plants from home-saved seed—for in this case it often happens that the greater percentage of blooms is of an inferior quality. T. W. B.

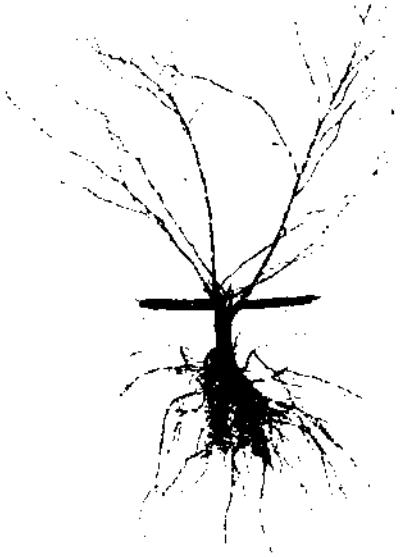
HINTS ON ROSE PLANTING

This is the second of our series of articles on rose culture. On this occasion the author deals with planting and the cultural points that make for the ultimate success of the plants.

AS with other plants so with roses, there is a correct method of planting and also a wrong one. The beds or borders being in readiness and the plants at hand—about the beginning of November—planting may begin provided that weather and soil conditions will permit. If the weather is wet, or if the soil is laden with moisture or is in a frozen state, planting must await a more favourable occasion. The first concern that arises under such circumstances must be the proper care of the bushes until suitable conditions prevail. If planting cannot be done immediately after the arrival of the plants, they must be heeled in until they can be dealt with. They should be removed from the package and laid singly in a trench so that the roots are buried and kept moist in the soil. They can remain in the trench with all safety until the beds are in a suitable state for proper planting. This treatment is most essential if the best results are ultimately to be obtained from the plants.

Roses should never be planted unless the soil is in a fairly dry condition. This particular condition is often a puzzle to many amateur growers, but it need not be so. To begin with, it is most necessary to plant roses very firmly; many failures arise from the neglect of this primary need, and it is far too often overlooked. Firm planting can only be done when the soil is in a fairly dry state, and if it is done when the ground is wet the soil simply becomes caked and hard. To tread upon wet soil in order to firm up the plants is certain to result in trouble. In some soils the earth becomes like concrete; air and light are excluded from the roots; moisture cannot penetrate from the surface, and unhealthy conditions ensue with disastrous results in future.

The proper condition of the soil can easily be determined. If it adheres to the spade—owing to excessive moisture in it caused by recent rain—it is not in a state for planting; if it clogs the boots when attempting to tramp it in order to firm the plants, it is also in an unfit condition for planting. A day should be chosen, therefore, when the soil is in a nice dry state and every operation connected with planting can be carried out in a satisfactory manner. The roses are safely heeled in in their trench awaiting such conditions, and there need be no anxiety concerning them if things are not right upon their arrival from the nursery.



A GOOD ROSE PLANT.
The line indicates the depth to which it should be planted.

Two feet apart is the general rule in planting. A hole should be taken out 2ft. square and about 1ft. in depth. The plant is put in the centre of this hole, and the roots are then spread carefully out in as natural a manner as possible. The soil is then filled in and firmed up with the foot as the work proceeds, taking care not to injure the roots in the process. It is most necessary to observe that the point of junction between stock and scion is not buried too deeply, and care must also be taken to see that it is not exposed above the surface of the soil. The proper depth for this junction is 2ins. from the surface. The bushes can easily be put in at that depth when planting by holding them in the centre—with a glove on the hand, of course—and raising them gently up in the soil until the proper depth is attained. Firm up the soil as the planting proceeds, and do see that this most important part of the work is not neglected.

The point of junction between stock and scion is that part of the plant where the rose has been budded upon the briar. The accompanying illustration shows a plant and the line across indicates the proper depth for planting. The spread of the roots will also be noted and, as already stated, these should be carefully spread out in the hole made for the reception of the plant. It is a mistake to put the plant in and then to fill in the soil around the roots in a haphazard way. If the roots are filled in a crowded condition growth is certain to suffer. You do not plant roses every day; take ample time and do the work properly.

It may be as well to state the reason for the point of junction between stock and scion being only about 2ins. below the surface of the soil. If it is planted much deeper light and air lose their beneficent influence upon it; in a word, it is smothered and is incapable of making fresh growths. On the other hand, if it be above the soil level, it becomes hardened and the dormant eyes

Digitized by Google

or buds upon it do not break into growth in consequence. Two inches is an ideal depth, and this must always be aimed at, not only after planting, but always throughout the life of the rose. If the soil subsides and exposes the junction the error can be remedied by a suitable top-dressing of loam. If the roses are seen to be too deep owing to frequent top-dressings, some of the surface can easily be removed.

The point of junction is a very vital entity in a rose plant, and the necessity for its proper care is most apparent. If you examine a plant you will find that the bud, or eye, which was inserted in the briar stock, has swollen very considerably and the shoots of the rose emanate from this excrescence. As the plants grow and increase with age this swelling extends and gradually becomes much larger. It is from this excrescence that every future rose shoot of any strength arises. It is full of dormant eyes, and these break into growth from season to season and literally create a fresh bush every year. Much of this fresh growth, of course, is promoted by proper pruning, but this will be dealt with in due time. I may appear to have somewhat laboured the point as to the junction of stock and scion, but I make no excuse for so doing, as it is a thing too often neglected in rose growing. It will be seen, then, that a sharp watch must always be kept upon the plants in order to make certain that the proper depth is maintained.

Be sure that no manure of any description is in immediate contact with the roots of the plant. Make certain that all manures are beneath the roots—it need only be 2ins. or 3ins. to begin with. Contact is fatal and causes a severe check from which the plants may not recover if fresh, or undecayed, manure has been used. If the ground has been manured in accordance with the instructions contained in my last article, no further manure will be required until the following season. Let your plants make plenty of roots and so become thoroughly established before applying further stimulants. Established plants can stand plenty of feeding, newly planted rose bushes simply cannot.

The final point in planting is to avoid a top-dressing or mulch of manure. Such a thing is most harmful in the case of newly planted roses. It excludes light and air; promotes dampness in the soil; it rots the young roots. Keep the surface loose with the Dutch hoe. This ensures thorough soil aeration, and it gives the roots full benefit of the warmth of the earth. Top-dressing on account of protection from frost is a fallacy, and such practice often results in heavy losses. The modern rose is a hardy plant, and protection is neither desirable nor necessary. In a very severe winter you may put some light, dry bracken or something of a similar character over and between the shoots or branches. Never apply a winter mulch of manure. GEO. M. TAYLOR.

HOW TO GROW LILIES OF THE VALLEY

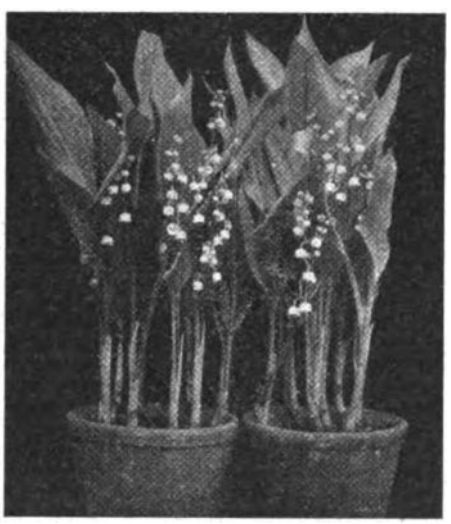
THIS beautiful plant is of easy culture provided care is taken in the preparation of the bed and due regard paid to its natural requirements.

The preparation of the bed should be thorough. It should be double dug and a good dressing of well decayed manure incorporated in the bottom spit. It is necessary to have well decayed manure, and the manure from an old hot-bed is excellent for this purpose. The top spit should have some leaf-mould and sand incorporated with it. A good rich loamy soil well drained is an ideal soil for the lily of the valley. As this plant naturally likes shade, a north, north-west or west aspect under a wall or fence is usually the best one, though for early flowering some crowns may be planted on a south aspect if provided with shade.

Crowns may be purchased from a nurseryman if a new bed is to be made; but if the bed is to be remade crowns may be selected from the old plants for replanting. The lily of the valley has a creeping rootstock which throws up growths which are called crowns. These are detached with a portion of the rootstock, and the plumpest, being those of two seasons' growth and therefore most likely to flower in the following season, should be selected for replanting. The thin pointed crowns are only of one season's growth and should not be used unless there is an insufficient number of plump crowns available for planting.

Planting.

The best time to plant is during early autumn. The crowns should be planted 3ins. to 4ins. apart and the tops of the crowns just covered with the soil. A mixture of rich loam, leaf-soil and sand should be worked in among the crowns at the time of planting, and the planting should be fairly firm. Once properly planted the bed should be left undisturbed for a number of years. An annual top-dressing of well decayed manure in the autumn, *i.e.*, September or October, should be given, and it will be necessary to cover the beds lightly with bracken or brush in the case of severe frosts. The lily of the valley produces two leaves only, and when picking the flowers and leaves this should be borne in mind, as by robbing the plant of both of its leaves you are taking away its means of obtaining food material from the air. This food material is necessary for the building up of fresh flowering shoots for next season. Therefore, as few leaves as possible should be plucked. Gather the flowers by giving the stem a sharp upward jerk, when it will come away easily and avoid injuring the crown. Two good varieties are Fortins Giant-flowered and Victoria.

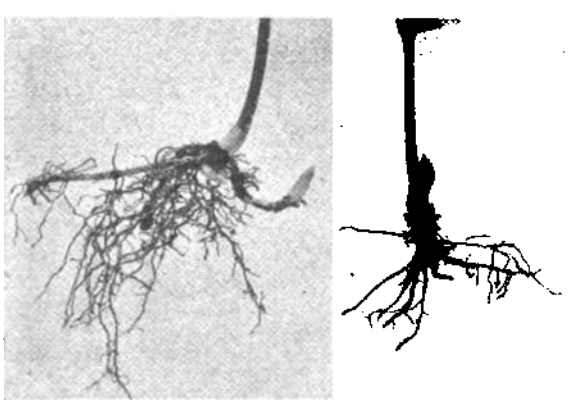


LILY OF THE VALLEY PLANTS FOUR WEEKS AFTER PLANTING RETARDED CROWNS.
An easy way of obtaining flowers for Christmas decoration.

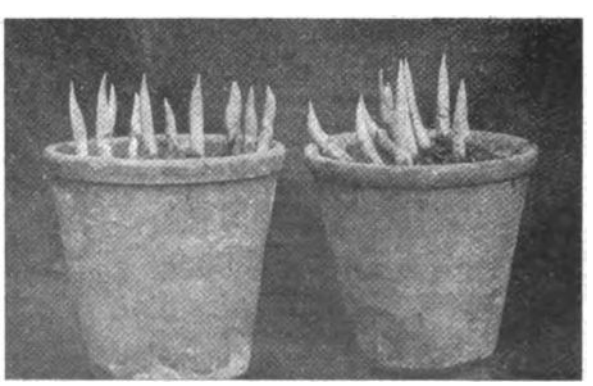
Lilies of the valley are much used for decorative work and for cut flowers, and are particularly adaptable for these purposes, as they may be made to flower over a very long period either by forcing or using retarded crowns.

Forcing.

Forcing can only be carried out to its fullest extent by those who have adequate heating facilities at their disposal, although lilies of the valley can be obtained earlier than outside by ordinary pot culture in ordinary greenhouses. The crowns selected for forcing should be well plumped (two or three years old) and planted in pots or boxes ten to twelve crowns per 5in. pot in any light sifted soil. The points of the crowns should be just showing above the surface of the soil and the pots plunged in coconut fibre or ashes for two or three weeks until root action commences. One good watering-in is given at the time of plunging. When root action has begun the pots are brought in to a moist dark chamber and at a temperature of between 85° and 90° Fahr. The pots covered with 2ins. of moss, and should be given an abundant supply of tepid water daily. When the shoots are 2ins. to



A thin-pointed crown which will not produce flowers the first year, and a plump bud that will. These points should be noted when selecting new crowns for planting.



Retarded crowns when potted up make rapid growth. The pots should be kept in the dark until the leaves begin to unfold.

Digitized by Google

3ins. in height the moss is removed and light gradually admitted. When the flower heads appear the pots are removed to a somewhat cooler place and receive more light. By placing successive batches in the forcing chamber a continuous supply of flower is obtained.

How to Succeed with Retarded Crowns.

One of the simplest forms of flower culture is made possible by the system of retardation which has been carried out most successfully in the case of lilies of the valley. Even in a living-room it is possible to have these lovely flowers in full beauty in such a short while as to make the whole business seem almost magical. Of course, the "crowns," as the roots are called, which one buys at the present time would, in the ordinary way, have flowered last spring, were it not for the fact that they have been kept in cold storage. As soon as they are brought into quite a moderate temperature the plants start to grow vigorously, producing plenty of foliage in addition to the flower spikes. Nothing in the way of forcing is really needed, although, naturally, a genial atmosphere will hasten growth. Anything like cold air is very harmful to the delicate shoots, and this kind of thing must be avoided at all costs. In mid-winter the writer brought the plants shown in the illustrations into full flower in exactly twenty-four days from starting. The lilies were started in the kitchen and then finally brought into the dining-room to complete their development.

Although the growing of retarded lilies of the valley is easy, it is important to pay attention to a few points. Ordinary pots are the best, but, instead of soil, use bulb fibre. See that there is a liberal amount of drainage in the bottom of the pot, as it is important that the rooting material should not be in a water-logged state. Plant each crown separately, setting it with the pink shoot well above the fibre. Allow about eight or ten to a 4in. pot, spreading the roots out as much as possible. Growth is very much hastened if at the start the lilies are kept in a dark or at least a heavily shaded place. In fact, there is no particular object in exposing the plants to full light until they have started to unroll their leaves. If the lilies are placed in a cupboard, leave the doors ajar so that some air can get in. When the lilies are being grown in a greenhouse, a position under the staging is admirable, and here the growth will be very rapid, always providing the temperature does not sink too low at night. The question of watering is of great importance. Never use absolutely cold water, or a very severe check will be imposed on the plants. Use water with a temperature of about blood heat, not only for the actual watering, but also for overhead sprinkling. Do not keep the fibre in a sodden state, although it is most important that it should never be allowed to become absolutely dry. By the time the leaves begin to unroll the spikes will be a good height, and it is then that the plants may be brought out into a lighter position. Do not at once expose them to a very strong light, or a check in the development of the plants will take place. It is a mistake, at any time, to allow the lilies to stand in direct sunshine, as this will often cause a drooping of the leaf and flower stalks from which they do not always recover completely. After flowering the crowns are exhausted and it is not worth while planting them again in any position.

L.

MAKING A ROCK GARDEN on LEVEL GROUND

The hints given in the following article may prove useful to those who are thinking of constructing a rock garden this winter. They are the outcome of practical experience.

THE making of a rock garden in a dell, or where there is a good slope to the ground, is comparatively easy work; but a flat piece of ground presents many difficulties, especially to the beginner. This must be the writer's excuse for giving some description of the making of a little rock garden on a perfectly flat spot.

The piece of ground selected was covered with turf, being good old pasture, and the turf was pared away very thinly and stacked, to be afterwards used for potting, or for choice plants on the rockery. Below this there was a good spit of loamy soil, with a fair amount of fibre in it, and this was thrown or wheeled to some little distance, so that it could easily be brought back again to make compost for the rock plants.

It had already been planned to gain higher elevations by sinking the centre of the rockery about 3ft. below the general level. A set of rough steps at each end, with a slightly winding path through the work, completed the simple ground plan. Upon this point some experience was dearly bought, for time soon proved that in excessively wet weather the rock garden could get flooded, and it was afterwards necessary to lay in a drain, commencing at the lowest point of the path, and carrying the water to another part of the garden where there was a natural fall. Except upon very light and porous subsoils, such drainage appears to be essential.

It is not wise to start making a rock garden without some definite plan, imitating or trying to reproduce something seen in a mountain district. The design in the present instance was to make a rocky gorge, with a few bold promontories and sheltered hollows between.

For good or for evil, the work was started in August, and the labour of shifting that baked mixture of clay and stones was stupendous. But rain soon came to help us, and we got the foundations of our effort duly planned. Some misgivings arose as to the suitability of such material for the foundations of a rockery, but as we intended to cover the whole with at least 1ft. of good soil, there was a prospect of many things doing well. After experience proved that some rather choice plants pushed their roots down into this mixture of stones and clay and yet remained perfectly happy.

A CORNER OF A ROCK GARDEN MADE ON A LEVEL PIECE OF GROUND.
The various height levels have been obtained by careful planning, and add much to the beauty of the garden.

At the time of making it was absolutely necessary to use the best materials close at hand, and an adamantine stone found locally in isolated blocks or layers, of the conglomerate order, was that chiefly used in the making of the rock garden. This kind of material is banned by all experts, because of its excessive hardness; but we were afterwards successful with the great majority of the plants that were used.

The work proceeded on fairly orthodox lines, forming large and small pockets as we went, and bedding the stones to look as if they were level strata, naturally cropping out of a hillside. The loamy soil before mentioned had some sand and rock chippings mixed with it, and this was put between and beneath the stones, so as to give a depth of from twelve to eighteen inches everywhere. This proved excellent material for common rock plants, and special pockets were made up for choice subjects as they were procured. Some experience was bought, and if starting again I should use more sand and rock chippings, for our heavy loam seemed to have a fancy for reverting to clay after it had been in use for a time. It would also be desirable to give the pockets a greater slope, for all rock plants have the best of drainage in their native homes.

The original intention was to plant the outer banks of the rockery with dwarf shrubs, so as to hide it entirely from its surroundings; but, being greedy of space for plants, the outer sides of the banks were also turned into rockery, the irregularity of contour and height on the inside being repeated. So doing gave positions in sun and in shade, facing all points of the compass, a very desirable thing for even a modest collection of rock plants.

The pathway through the middle of the garden was roughly paved, and many little plants found a home between the stones. A grass path was made all round the outside, with a few stepping stones let in where it was likely to get much trodden. This gave an opportunity for having large spaces at the foot of the rockery for planting gentians, anemones, primulas and other plants that prefer a cool, deep soil.

The lack of water to make a pool was a considerable drawback, but it was thought best not to have the muddy, ill-supplied arrangement found in some rock gardens. With copious waterings a few plants of the boggy order did well in the beds at the base of the rockwork.

THE BUSY MAN'S PAGE

Planting Trees and Shrubs.

ALL trees, shrubs, hedges and woody climbing plants may be planted from the late autumn onwards until the spring, providing the weather is open. Of course, no planting of any description should ever be attempted during a frosty spell. Trees and shrubs which have been well packed will come to no harm if kept in a cool cellar or a shed where there is no risk of the frost getting at them. It is worth waiting a little while should the weather be very wet or in a quite unfavourable state. Where, for any reason, planting has to be postponed for a considerable period, open up a deep trench and cover the roots, and some distance up the main stem, with loosely scattered soil. When the trees are unpacked the roots should be examined, and any that are bruised or otherwise damaged should be cut back with a sharp knife. It is also a good plan to shorten tap-like roots to a considerable extent. If the roots seem very dry, soak them for an hour or so in wet soil before planting is attempted. The hole in the ground that is made for the plants should be large enough to allow the roots being well spread out. If turf can be obtained it is really an excellent idea to lay this, grass side downwards, in the bottom of the hole to act as food and drainage. The stem of the tree or shrub will show how deep it was in the ground in its last situation, and it should be replanted to the same depth. With the tree in position, spread out the roots well and then start working in the soil with the hands. Only fine soil should be employed at this stage, and it is most important to get it thoroughly between the roots, so that there may be no air pockets. After about 6ins. of soil has been worked in, light treading may be started. Complete the filling with a spade, treading more firmly as the roots get well covered.

If it seems likely that the tree will need a stake, this should be well hammered into the hole before filling in, and the tree tied to it with a padding of woollen stuff and little pieces of wood to prevent the cord cutting through the tender bark. When the tree is grafted high up it must be firmly tied both above and below the graft. If fine and fairly good soil is used, there is no occasion for putting manure into the hole.

LIFTING GLADIOLI.
Note the bulblets round the base of the new corm.

Lifting and Storing Gladiolus Corms.

THE time has arrived when gladioli should be taken up and stored for the winter, and as there must be many readers who have grown them for the first time this season, a little advice now may, perhaps, avoid disappointment later.

While I am well aware that, in sheltered gardens in the south of England, gladioli corms are sometimes left in the ground all through the winter, this is, at the best, a doubtful procedure, and little or nothing is gained in the long run by practising it. Undoubtedly, it affords the means of obtaining early flowers the following season; but, even should the corms survive frosts, they must be lifted the second year or they will certainly become far too overcrowded.

The end of October is about the best average time to lift, for, although gladioli may be lifted a month or more earlier, it is wise to allow the new corms a fair chance to develop fully and to ripen, especially in a season like this, when many corms which would have flowered in a normal year have failed to bloom, solely on account of the cold, sunless weather conditions.

Experienced growers must forgive the brief explanation—for the benefit of beginners—of what a gladiolus plant is like at this time of the year. Suppose what is termed "flowering-size" corms were planted last spring, well, each corm has thrown up during the summer one, two, perhaps three separate spikes of leaves, from which in most cases developed a flower spike. On lifting the plants, at the base of each of these spikes of leaves will be found a new corm. The old corm, which was planted, is now quite withered and will be attached to the bottom of the new corm (or corms), while in between the two, clustering all around the base of the new corm, there are miniature corms, termed "bulblets." The actual number of these bulblets round each corm will vary from three or four up to a hundred or more, according to the nature of the variety, the soil, the depth planted, the age of the old corm, and the season. As regards lifting, the most convenient method is to dig up the plants carefully, gently removing most of the adhering soil. Practically all the bulblets will be attached and these should be left as they are for the present. Then hang up the plants, roots downward, in a cool conservatory or greenhouse, or in an airy shed, to dry. An alternative method is to lay them out thinly on bags on sunny days, taking care to bring them indoors if frost is expected. In about a fortnight the foliage will have turned brown and dried; then cut off the leaves and flower stems about 1in. above the new corms and pull the withered and useless old corm forcibly away. Clean off any soil and loose skin from the new corms, and remove the bulblets, afterwards laying both bulblets and corms out thinly on to trays or in boxes. If convenient, the corms and bulblets may be stored separately, the latter (if perfectly dry) will not harm in paper bags or cardboard boxes. Store them in some cool, dry and airy position which is quite frost-proof, until planting time comes round again. It is hardly necessary to add that each variety should be correctly labelled and kept separate throughout.

With regard to the bulblets, the large majority will not flower the first year they are planted, but most of them should bloom the following season. Sow them in early March in deeply dug, fairly rich soil, in drills like culinary peas, making the drills 2ins. to 3ins. deep, about 1ft. between each. Sow thickly and it will be found that several hundreds will take up little room and will need no attention beyond keeping clean and, of course, lifting and drying in the autumn as previously explained. In case some inexperienced growers should be needlessly alarmed, I might mention the fact that often bulblets "germinate" irregularly, some appearing through the soil weeks or even months after the first have made their appearance. Indeed, occasionally a few bulblets will remain dormant all through the season. If not considered too much trouble, it will greatly facilitate "sprouting" if the hard brown outer skin of the bulblets is cracked or entirely removed. They provide the easiest and quickest method of rapidly increasing one's stock of gladioli, and with the newer and expensive varieties it would be wasteful to neglect them.—C. H. A. S.

DRYING THE CORMS AFTER LIFTING.
Care should be taken that each variety is labelled.

The General Clean-up.

AUTUMN time is the time for the general clean up in the garden. Hoe up every weed that can be seen. Clean the cabbage bed of decayed leaves. Pick off stones, sticks, etc. Go round and collect up all spare pea sticks, plant labels, etc., and bundle them up. Dig all ground that is clear. Sharpen all tools. Prune where necessary, and help climbers if needed. Lift all matured crops.

The Rock Garden in Autumn.

THE rock garden must be cleaned at once. Everything seems to have overgrown itself, and some drastic cutting back must take place. Aubrietias, alyssums, rock candytuft and roses can be cut right back. Little more than bare stalks need remain. These will shoot well next spring. With the creeping alpines, such as saxifrages, the surplus can be pulled out with the hand. Do not forget to fill the empty pockets with cuttings, and exchange with your friends. Add more sandy soil where necessary, and clear all leaves which have blown on to the rockery. Be careful to weed thoroughly.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Town Garden Soils.

A FRIEND living within a stone's throw of Eccleston Square, Westminster, finding that the garden plants did not thrive, submitted samples of the soil for analysis. The analysis, which is typical of all town soils, reveals that the soil is poor in nitrate and phosphate, but rich in humus and potash. A considerable trace of sulphurous acid, due to the smoke, is present. Such a soil would benefit by the application of basic slag and bone meal, applied at the rate of an ounce of each to the square yard. Although there is a small quantity of lime in basic slag, additional lime should be applied at the rate of 2 oz. to the square yard. This would counteract the injurious effects of sulphurous acid. Lime also releases potash and assists useful soil organisms.

An Attractive Front Garden.

OF all the front gardens were cultivated as well as the one illustrated herewith how much more beautiful would our roads become!

The design is simplicity itself, and the grass and borders are so arranged that any of the plants are within reach without walking on the soil. In such a garden there is much to do this season.

Annuals that have finished flowering should be lifted and the site prepared for spring flowering bulbs. Perennials, too, that have finished flowering can be cut down, and the whole border forked over, burying any surface weeds and decayed leaves. Where clumps are overgrown, they, at the same time, should be lifted and a few of the stronger shoots replanted.

When forking is done a dusting of lime would be advisable at the rate of 2 oz. or 3 oz. to the square yard. This assists the decomposition and conversion into plant food of the vegetable matter and plant tops which are buried as digging proceeds.

If the soil is impoverished an application of basic slag, which is a slow-acting fertiliser, would be advisable. This is especially suitable for heavy soils, and it needs to be applied at this time of the year as it is slow in action and would not be available as plant food until next spring. Apply it at the rate of 2 oz. to the square yard.

A Rock Garden on a Roof.

IN many ways, rockery plants are the most successful class of plants to cultivate on a roof garden. They do not mind dry atmosphere; an occasional drying-out of the soil does not hurt them, and when once planted, the roof-rockery requires very little attention. The essential thing is to mix plenty of grit with the soil when filling the pockets between the rockery stones, and to plant subjects like sedums and saxifrages that do not mind dry conditions.

A WELL FURNISHED AND SKILFULLY PLANNED ROOF GARDEN.

Much ingenuity is displayed in the roof garden illustrated on this page. Cement pockets filled with soil have been provided for the plants, and on the coping of the wall a cement trough affords a home for many rockery gems. In big cities there are many flat-roofs that could be utilised in this way, and the Blackheath roof garden is an example of what can be done.

Now is the best time to construct and plant such a garden so that the plants will become established by spring.

MAKING THE MOST OF A SMALL FRONT PLOT.

Here is a garden made and tended by an amateur, that should encourage others to make a similar display.

The Value of Falling Leaves.

TO the gardener, leaves may be either a source of annoyance or an invaluable addition to his store, according to whether he leaves them to rot on the surface of his paths or collects them for use as manure. Leaves collected and stored make a useful base for artificial fertilisers, adding the necessary "humus" to the soil.

If you are so fortunate as to have a good supply, collect them all together. Use some to fill the bottom of your cold frame, treading them well down and covering them with a layer of soil. Store the rest in heaps, covered with soil until they rot. They can then be used for potting, for digging into borders, and especially for preparing soil for lilies, ferns and other woodland plants.

How to Dig Properly.

THERE are several ways of digging, according to the nature of the ground to be dug. If it is an ordinary flower border, all that is necessary is to take out a shallow trench at one end, into which annual weeds and dead vegetable matter, together with any manures to be applied, are placed. Another width of soil is turned on to this, which again leaves a shallow trench. This means working backwards along the border, and if there are plants in position, these can be either lifted and divided, or simply dug round. This will, of course, interfere with a straight trench, but a little practice will soon make one accustomed to the work. Endeavour to leave the surface soil so that it will be perfectly level when the lumps are raked down. With heavy soils it is inadvisable to rake the surface level until spring.

Deep digging and lime promote the growth of the useful soil bacteria. They convert the nitrogen of the atmosphere into plant foods, which can be absorbed by the root hairs.

THIS WEEK IN THE FLOWER GARDEN

Late-Flowering Chrysanthemums.

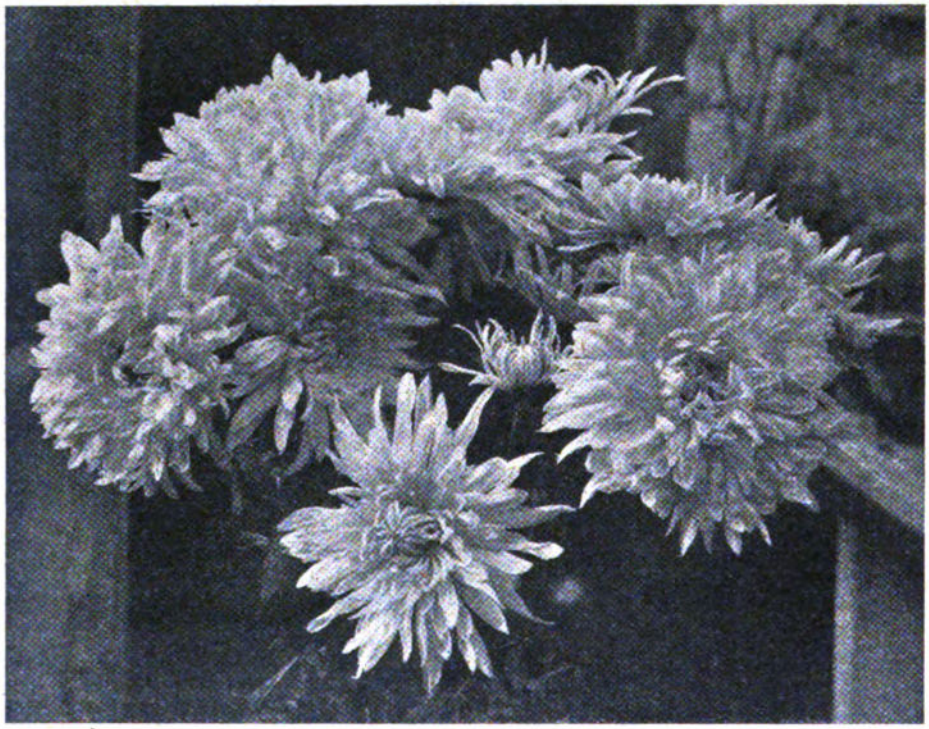
Lift plants from outside and transfer them to the greenhouse.

THE production of those fine indoor blooms depends largely on the method we adopt during "lifting-time" at the end of October. The late-flowering plants, those grown for their large, choice blooms of November and December, should now be transferred to their flowering positions indoors. Careless handling now may undo the work that we have expended on these plants during the last few months.

The cycle of their growth has proceeded throughout most of the year, and now the crown buds should begin to show signs of breaking. Provided the taking of the cuttings and the growing of the plants have been on the right lines, we should have some sturdy plants showing one, two or three main stems, according to whether we desire one large flower to each plant or several medium large ones. There is no doubt that the finest blooms are produced indoors, yet we know quite well that chrysanthemums do produce blooms out of doors, and good ones, too. We also know that if we leave our late plants out and the season is mild, they also will start to show their colours, but the blooms would not be of such good quality as those from plants transferred indoors at the right time. I recommend that these plants be lifted and placed into indoor positions well before the buds break and before the early frosts make this imperative.

The first frosts are low on the ground and they catch the lowest leaves of the stems first, with the result that they go brown and curl. As soon as this is noticed we must delay no longer in the matter of lifting. Transferring the plants from outdoors is necessary for more reasons than protection from the frosts. Wind and rain work havoc with them, and the insects have not all gone, while under the glass the flowers have the full benefit of the sun's enfeebled rays.

The lifting should be done on a fine day if possible, and the plants can be potted or planted out. It will not be possible to lift without disturbing the roots going deep down into the ground, but this is not very important so long as we do not disturb the flower-producing roots, which lie more on the surface and around the stem. The soil into which the plants are placed should be prepared beforehand, of course. Leaf-soil and sandy loam, with an admixture of old burnt wood ash, make an ideal soil compost. In replanting, the roots must be placed well down into the soil firstly, because the flowering roots lie near the surface and deep planting will encourage the growth of these, which in turn provide for larger blooms; secondly, because we must encourage the growth of "cuttings" for next year's plants and which spring up stronger with a deep planted root.



AMONG AUTUMN FLOWERS THERE IS NONE CHOICER THAN THE CHRYSANTHEMUM. *Plants outside should be lifted and removed indoors for a greenhouse display without delay.*

After a week in their new positions the plants can be fed with liquid manure, weak at first; also we can pinch off the buds not required to flower according whether we desire large single blooms or for indoor decoration.—D. L.

Planting Hedges.

AS a hedge must stand a long time without further cultivation, every effort has to be made to work the soil up well before planting commences. Not only ought it to be trenched, but manurial matter may be, and often is, required; rotted manure, leaves, soft rubbish and the like are good, but a coarse bone meal or a little hop manure may serve. Plants which shed their leaves in winter are planted when they are bare; evergreens are best planted in early autumn or in spring. Whenever the shrubs arrive, ditch them in, in a vacant plot of the garden, but see that they are put into permanent quarters at the earliest opportunity. The number of shrubs required varies with the kind desired; seedling thorns, beeches and such-like may be two to a foot, or, to secure a close, impenetrable hedge, three; evergreens may be one to the foot, or even one to two feet if the bushes are large. Soft shrubs, like the privet, can hardly be planted too thickly, although one to 6ins. is the rule. Plant firmly and, in order to secure a very close and neat hedge ultimately, like this ●●●●●●●●, rather than this, ●●●●●●●● Thorns, privet, beech and the like may be cut back to half size at the end of March next; evergreens are best allowed to grow for a year before they are clipped back hard.—LANARKSHIRE.

Some Uncommon Early-Flowering Border Perennials.

HOW much brighter the majority of herbaceous borders could be during the month of June, if only a little more thought was expended on them.

Most people regard June as a month when there is not much bloom in the border except for such subjects as lupins and poppies, but if the depths of some of our numerous catalogues were probed they would reveal many. I would like to mention a few which would help to supply colour to the border and at the same time add interest, charm and character.

The first is Hedysarum coronarium or the French honeysuckle, which is a handsome herbaceous perennial bearing resemblance to the sweet and everlasting peas. It has divided leaves having oval leaflets, downy beneath, and spikes of crimson flowers. The plant is about 3ft. to 4ft. high. It can be easily propagated either by seeds sown outdoors in April or May and transplanted to their flowering quarters in autumn, or sown in heat in winter, hardened off and transplanted in spring. It thrives in almost any soil, but should have a sunny position and a little shelter, if possible.

The amateur gardener who has a small border could hardly find anything better than Mertensia sibirica, for it is distinctive, beautiful, compact and easy to grow. It has nearly heart-shaped lower leaves and blue flowers on 18in. stems. It thrives in a good friable soil if the situation is not hot and dry. Partial shade with a cool peaty soil suits it best, and it is increased by division in autumn or spring.

Another plant for the small border is the Tradescantia virginica. It also makes a good town plant, thriving in most soils, and is not fastidious as to situation, making itself at home in rather shady as well as in sunny places. Propagation is by division in spring.

A plant worth growing in a large border is Symphytum caucasicum, with blue flowers, which will thrive in most soils and is propagated by division.

Centaurea macrocephala provides a most interesting plant, with its charming thistle-like heads of an old gold colour which later develops into large yellow heads.

Poterium dodecandrum, with its rosy purple, handsome spikes, is the very old pot herb of which the leaves were used in salads and soups; it is suitable for a light friable soil and is propagated by division in spring.

If one added to this list linarias, some of the thalictrums and salvias, one would never complain of having a dull border in June. —M. H. G.

Pruning Rambler Roses.

ROSES of the rambler class should receive immediate attention to enable the growths to secure all possible benefit from air and light. The wood will then be perfectly matured, will withstand frost and produce plenty of blossoms next summer. It is a great mistake to defer thinning out the growths too long. The ripening period is between now and the end of November, and should the weather be mild the growths

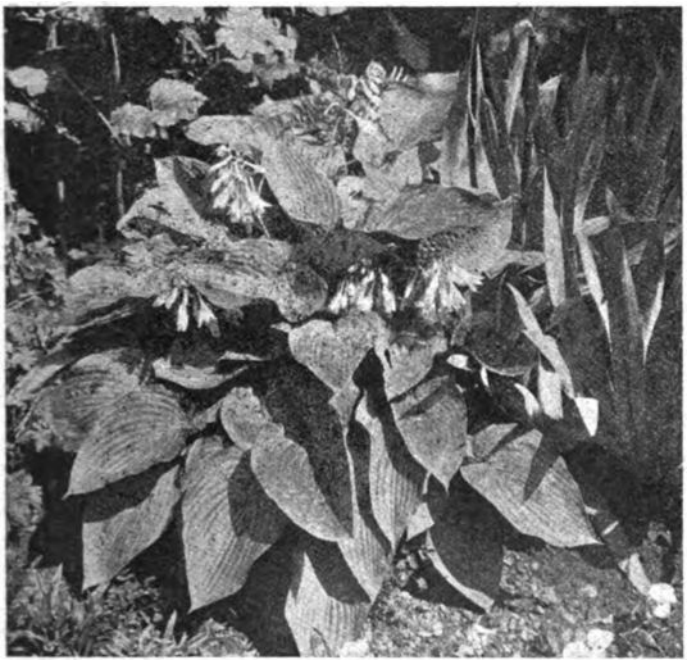
Digitized by Google

sheltered, or, in other words, coddled, will be so weakened as to be useless. When this is allowed to take place the after result is often disastrous if cold, frosty winds come on the scene.

In pruning this class of roses all, or nearly all, of the old wood should be taken away. Circumstances must, however, be considered. If there is as much young growth as will adequately furnish the desired space, remove all the old wood, selecting the best ripened wood to take the place of that removed, and by no means place them closely together. —J. A. P.

Funkias for the Border.

A PLANT that deserves to be seen more often than it is in the herbaceous border is funkia. It is most conspicuous for its bold and handsome foliage of large veined leaves measuring some 7ins. across, which are ornamental from their first appearance



FUNKIAS ARE AMONG THE BEST PLANTS FOR FURNISHING A SHADY CORNER IN THE GARDEN.

at the end of April or in early May till the end of September; but it also bears most attractive flowers in July of a very pale lavender—almost white with a lavender tint. The leaves spring direct from the root and die down in autumn, so that the plant is out of sight. They are rather late in starting, and it does not follow that the plant has perished if nothing appears when most other herbaceous plants are well forward. Funkia is very accommodating in the matter of cultivation. It may be planted in the autumn or early spring, and while it will grow luxuriantly in a sunny spot, it will also thrive quite happily in partial shade. The roots of well established plants can be divided in the spring before growth begins; but as the plant is out of sight after the leaves are off the middle of the crown should have been marked with a stick the previous autumn.—E. H. B.

Dahlia Our Annie.

THE dahlias this year have been making a brave show, and for bedding purposes Our Annie is one of the best. It grows about 2½ft. high and produces a wealth of its pretty shrimp pink flowers which stand well above the foliage. It belongs to the peony-flowered section, and the individual flowers are not by any means floppy and heavy, a characteristic feature of many belonging to this group. The blooms are about 4ins. across, dainty in appearance, and the shade of pink is sure to please, while it is very effective under artificial light. In a cut state it will be found useful for various kinds of decoration.—B.

A Good Plant for a Dry Wall.

Antirrhinum Asarina.

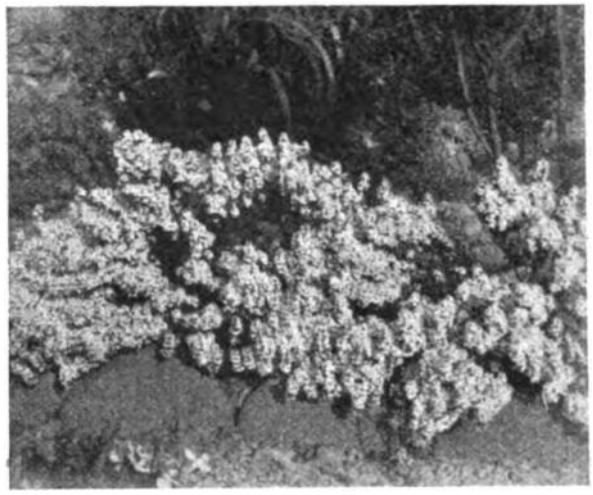
IF the subject of this note were to be given the name which would seem to have prior claim to the plant, we should call it Asarina Lobelii. But as Antirrhinum Asarina it has been generally known since the first specimens were introduced from its native Italy in 1699. For a really dry wall this is an ideal plant, and if the former is dust-dry with little or no soil the happier will it be. The specimen shown by the illustration over a yard across, appeared as a stray self-sown seedling, and so pleased is it with the site of its choice that it is becoming naturalised, odd seedlings cropping up all along the wall.

Though A. Asarina has no means of attaching itself, the hairy, sticky branches insinuate themselves so cleverly into the interstices between the stones that it never loses its hold. It begins its growth early, and before spring is over the pale yellow snapdragon flowers, faintly pencilled on the nose with red, begin to appear, and of these the plant maintains a succession until late autumn. If the plant is not a showy one, the downy, grey-green leaves are soft and pretty, the habit is singularly graceful and I know of none other that will do so well under conditions arid enough to try the endurance of a houseleek. A vertical position is obviously an advantage, but it is not always essential. Seed is set in abundance, and this germinates readily if sown in pans of sandy soil in a cold frame in spring. —A. T. JOHNSON.

A Beautiful Shrubby Thyme.

Thymus nitidus.

THIS beautiful thyme is without a doubt the finest of the shrubby species.



A PRETTY AND FREE-FLOWERING THYME, T. NITIDUS, OF SHRUBBY AND COMPACT HABIT.

Its small grey-green leaves are exceedingly fragrant, it makes a neatly rounded bush of some 9-12ins. in height and rather more in width, and this it adorns with rosy-white flowers throughout the spring months. So abundantly are these honey scented blossoms yielded that the whole plant is smothered with its fragrant burden. Then one may claim for T. nitidus that it is quite as hardy as the common culinary thyme and quite as easy to grow. It is an ideal shrublet for the rock garden or front of the mixed border, and I do not know of a better subject for associating with dwarf heaths. All it asks is a "place in the sun," and a free soil. It is very easily propagated by striking short twigs in pots of sandy soil placed in a cold frame, but even that is not always necessary, for most of these thymes will strike if fairly long pieces are dibbled-in in the open on a cool border.—J.

Sowing Seeds of Geums.

DURING October is the best time to sow the seeds of geums. The principal varieties grown are Mrs. Bradshaw, orange-scarlet; Lady Stratheden, golden yellow; and Orangeman, deep orange.

Sow the seed in boxes or pans and prick out 3ins. apart into boxes filled up with a good rich compost of loam leaf-mould and sand. Winter the boxes in a cold frame and plant out during March.

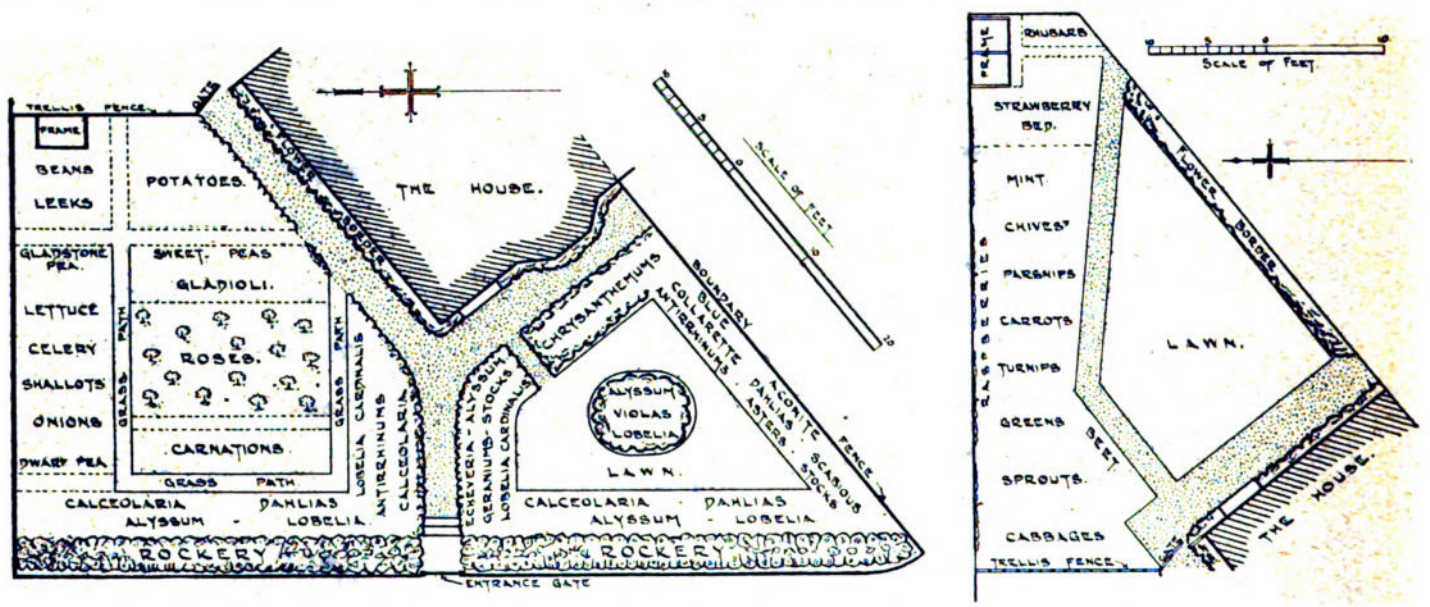
A PRIZE-WINNING GARDEN DESIGN

The garden, of which the plan is shown here, won the first prize in a Scottish Gardening Competition this year. The following article, together with the plan indicating how the success was achieved, may assist those of our readers who are thinking of entering for such competitions next year.

THE accompanying design, which was specially prepared for publication in THE GARDEN, represents the garden of Mr. James Stewart, Mosspark, Glasgow, who has been awarded the championship trophy for the best garden connected with the various housing schemes in that city. Organised by the *Glasgow Daily Record* for the purpose of encouraging horticulture among the thousands of tenants of Corporation property, a class which is increasing in numbers every year, it was made a condition that each garden must be cultivated by the owner or a member of his family and that any competitor who received assistance from a professional or jobbing gardener would be disqualified, thus enforcing a purely amateur status.



THE DESIGN OF THE FRONT AND BACK PLOTS, SHOWING THE PLANTING ARRANGEMENT.

The city is divided into seven groups, embracing twenty-two housing schemes, of which Mosspark, containing 1,500 houses, is the largest. Money prizes are awarded to competitors in each individual group, and the championship is decided by four judges from among the first-prize gardens in the various groups. The scheme, it may be further noted, has received the support of the leading members of the seed and nursery trades in Glasgow, who provide special prizes for the best cultivated plots of flowers and vegetables, and there are minor competitions for roses, sweet peas and rock gardens, and for the best kept paths and lawn.

This year's winner has advanced rapidly from novice to champion. Up till four years ago, when he took up his residence at Mosspark, he had never grown a flower, and recognising that he was up against a difficult proposition in the form of unsuitable soil conditions, he devoted all his spare time during the first winter to the work of trenching the ground. To-day he is reaping the benefits of the hours spent in arduous toil.

The first thing about the garden that is apparent to the reader is its peculiar and irregular shape. It is an entirely new design from that of last year, and it is generally acknowledged that in his latest attempt at lay-out Mr. Stewart has overcome the natural difficulties of the site by the creation of a well balanced scheme.

Another point which influenced the judges in their decision was the variety and quality of the subjects. It may be said of the vegetable garden that there is something of everything in it, and although some critics may take exception to an arrangement which associates vegetables with flowers in front, the combination does not detract from the general appearance, as the gradation from dwarf to tall peas is in keeping with the adjoining flowers. The potato patch took the form of a trial ground this year for the purpose of determining the varieties that were best suited to the soil. Nine sorts were grown, and Kerr's Pink proved to be superior, both in respect of quality and crop. The brassica family is represented by early, late and red cabbages, cauliflower, Brussel sprouts and greens, while the experiment of growing raspberries on the boundary fence of the back garden was justified by the yield of the crop.

As will be seen by the plan, the front or flower garden, which runs parallel with the road, is divided into two sections by the main walk running from the entrance gate to the front door. It is edged with stones, and little clumps of variegated arabis raised from cuttings and planted at irregular intervals afford relief to the formal straight line. The sloping frontage next the railing takes the form of a rockery, in which there is a representative collection of sedums and saxifrages. Immediately behind this there is a flower border extending the full length of the front.

The two divisions on the left and right of the path are treated as different schemes. Next the border on one side is a mixed bed of border carnations raised from cuttings, and beyond that is a bed of healthy-looking roses which have bloomed freely throughout the season. Rising above the roses is a group of gladioli with a row of sweet peas as a background, and, as the ground has a gentle slope from back to front, the various subjects are seen to advantage and constitute a pretty picture in harmonious colours.

On the other side of the walk the lay-out consists of an oddly-shaped green with a central oval-shaped bed clothed in blue and white flowers and a specimen of sea holly (Eryngium yuccæfolium) in the middle. The back border is occupied with early-flowering chrysanthemums, while the bed which serves as the southern boundary of the garden is filled with a collection of annuals (clarkia, lavatera and scabious), calceolaria and pentstemons, with a back row of collarette dahlias. As a substitute for the commonplace privet hedge a stately row of blue aconite towers above the flower border, giving an appropriate finishing touch to the colour schemes. The aconite, by the way, was planted by Mr. Stewart's neighbour and fitted in nicely with the general scheme.

The entrance walk is flanked by beds planted with antirrhinum and geranium in variety, calceolaria and Lobelia cardinalis, while the old-fashioned bachelor's button serves as an edging to the turf. A narrow flower border fully a foot wide skirts three sides of the house, and frames of various sizes occupy the odd spaces, for it is a creditable feature of Mr. Stewart's handiwork that he raises all his flowers from seeds and cuttings. Already the ground that was occupied by potatoes, shallots, carrots, etc., is fully planted up with cuttings, and these will be supplemented in spring with frame-struck cuttings of dahlias, geraniums, etc., an example of gardening economy which many amateurs might imitate. Dwarf Alyssum procumbens is used freely in the flower border and the total cost of the seed was 2d. So far Mr. Stewart has not divulged his intentions regarding his plans for next year's competition, but he means to retain possession of the trophy.

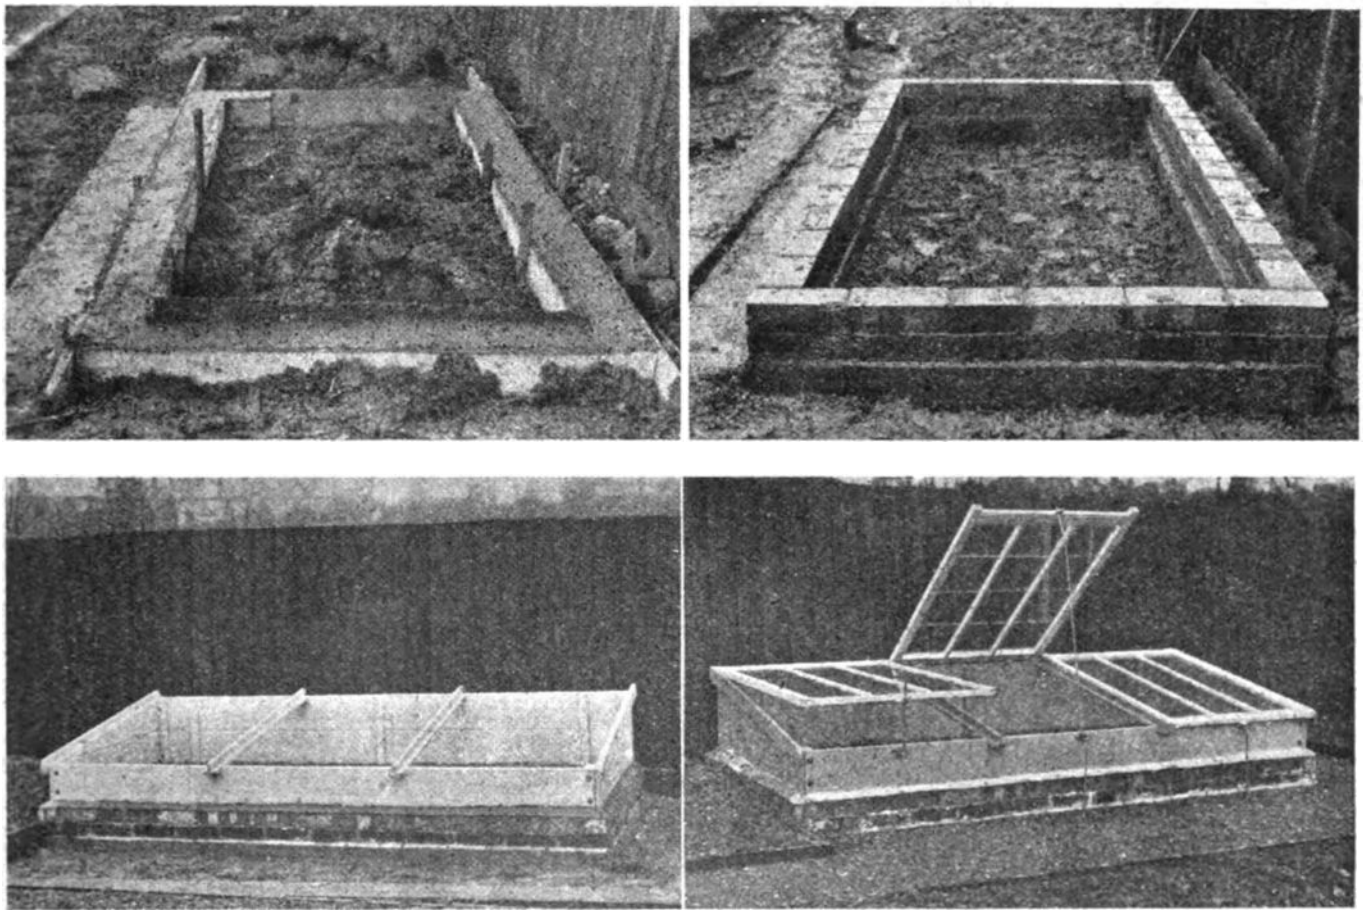
LAYING THE FOUNDATION FOR A GARDEN FRAME

Most amateurs prefer to purchase a frame in parts which are easily fitted together. The difficulty of providing a suitable foundation for the wooden framework, however, often arises, and this article illustrates how one can be simply laid with the aid of bricks and concrete. A brick foundation is to be prefered to one of wood since it is more durable and gives added protection to the plants in the frames. It is a job for the coming winter months.

ONE might go so far as to say that the equipment of no garden is complete without a frame of some kind or another. Nowadays there are many different kinds of frames offered, and the amateur may find it a little difficult to come to a decision. There is a good deal to be said in favour of the portable frame which can be moved about to different positions according to the purpose which it has to serve. For instance, such a frame can be placed behind a north wall when shaded conditions for the rooting of cuttings are needed; if melons, cucumbers, etc., requiring a more sunny position, are grown, the frame can be given a south aspect; while, at any time, the portable frame can easily be placed on a prepared hot-bed. Generally speaking, however, the permanent frame set on a brick or a concrete foundation is the better proposition. Indeed, a properly placed and well constructed frame is, in many directions, quite a good substitute for a greenhouse, at a cost which is very much lower than the more imposing structure.

Much has been written about the respective merits of the span-roof and lean-to frame. Of course, in the case of the span-roof there is a considerably greater depth than in the lean-to, and this extra accommodation may be very useful in the case of plants advanced in growth. On the other hand, a very large number of plants grown in frames do not require this depth; in fact, it is a sound rule that the closer young plants are kept to the glass the stouter and the stronger they will grow. The lean-to frame, with its comparatively shallow front and back and its fairly flat roof, facilitates the keeping of plants near the glass. In the case of plants requiring a maximum amount of sunshine, the lean-to frame is undoubtedly the better, for it can be placed in such a position that it secures a full south exposure. Quite a good depth may be secured in a lean-to frame by the lowering of the level of the soil inside. On a floor of ashes pot plants of some size could be accommodated in as healthy conditions as they would be likely to enjoy in a span-roof frame or even a greenhouse. A lean-to frame is cheaper than a span-roof one giving an equal amount of accommodation. When it is a case of buying just one frame, which will have to serve a great variety of purposes, there is no doubt that it is wise to decide on one of the lean-to variety.

It is poor economy to buy a cheaply made frame which has been put together in a slipshod manner. Where the wood is thin and the glass of inferior quality, dangerous changes of temperature will take place, and these may cause an infinite amount of harm to the plants. It will have but a short life, the joints of the body will open, the woodwork of the lights twist so that the glass is broken, and wherever the wood has touched soil or manure it will start to decay rapidly. The only safe plan is to deal with a firm with a reputation for sending out first-class articles. Get as large a frame as can be afforded, seeing that the small sizes are relatively more expensive. For instance, a lean-to frame measuring 10ft. by 3ft. by 1ft. 9ins. at the back is generally priced at about £6; whereas a frame of the same pattern, but 5ft. longer, can be secured for £8 7s. This additional 5ft. of accommodation will prove of great value, and the small extra cost is well worth while. The type of frame mentioned has two lights, but if the buyer is willing to pay rather more, he can get a three-light frame, which, in working, could easily be used for three different purposes. One of the sections might be devoted to pure sand, another to soil, and the third even to cinders. In such a frame it would be a simple matter to have rooting cuttings, seedlings or salad plants, and pot specimens, plunged in cinders, all at the same time. The fact of having three lights makes it possible to adjust the ventilation to the needs of the different parts of the frame. Thus, the cuttings would require a comparatively close atmosphere, and here the light would be kept down; more air would be needed by the growing plants, and perhaps still more by the subjects which are in a more or less quiescent stage in the cinder bed.

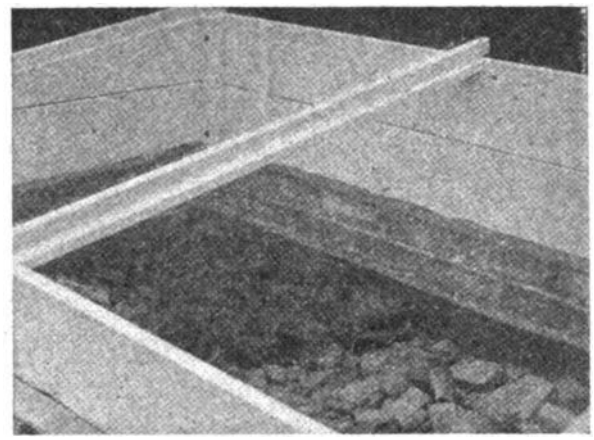


FOUR STAGES IN LAYING A BRICK FOUNDATION FOR A GARDEN THREE-LIGHT FRAME.

The first illustration shows the concrete foundation held in position by a mould, on which is set two courses of bricks as shown in the second. The third shows the framework placed and fixed in position on the brickwork; and the fourth the frame ready for use with the lights fixed.

Digitized by Google

It pays to give serious consideration to the position in which the frame is to be placed. It is always an advantage to have it where there is some protection from the north and east. An ideal place would be where the aspect was full south with a wall, fence or thick hedge on the north side and, if possible, something to break the wind coming from the east. Of course, in many gardens the ground is level, but where this is not the case select the higher part of the land as far as possible. A frame in any sort of hollow, even if the aspect is good, is in a thoroughly bad position. Here on still, winter nights the chilled air will settle, so that the frame is in a veritable pool of cold air. In marking out the site, leave at least 9ins. between any wall or fence, so that there is a clear way all round. In the illustration is shown a very good way of arranging the foundations for the frame. Here the bricks are set on a low concrete foundation which is somewhat wider than the width of a brick. The concrete wall is arranged so that it only comes a trifle above the level of the ground, and the shaping is easily carried out by the formation of a mould with lengths of wood. Of course, concrete may be made of broken bricks, cinders, stones, or coarse gravel with cement. Six parts of either of the above (it is better not to use mixed material) is allowed to 1 part of cement, the whole being worked up to a suitable consistency with water. Have the position and the wooden moulding all ready for the concrete before starting the mixing, so that the work of putting in the preparation may go forward without a check. The two or three courses of bricks which are added should not prove a very formidable job even to the amateur. If wished, these might be set in position without mortar, although, naturally, it is better to carry out the work with mortar in proper bricklaying style. The lines must be true and the whole perfectly level; but if the original concrete foundation has been properly planned, the bricklaying will be quite easy. When the frame is duly set on its foundation, cover in the part where the wood joins the frame with cement. Let the surface slope outwards and downwards, so that the rain may drain away at once. Take great care not to leave any spaces between the cement and the wood, as water is likely to work in even through quite tiny cracks. As has been indicated, a frame set up on the lines described can be used for a multitude of purposes. For instance, it is a very simple matter to use it for a hot-bed by taking out the soil inside as low, or even somewhat lower, than the concrete foundation. In the space thus secured the fermenting material can be snugly packed away and it will retain its heating properties for a much longer time than when a bed is made up in the open and the frame placed on the top.



SHOWING HOW THE DRAINAGE LAYERS SHOULD BE PLACED.
At least six inches of crocks and clinkers should be used as a drainage layer, with two or three inches of moss or loose fibre on top to prevent the surface soil from being washed down into the drainage. Each compartment may be treated separately and so can be utilised for different purposes.

In conclusion, it may be pointed out that it pays to make sure that the drainage of the ground in the frame is in order. In a frame damp is often a source of trouble, and the excessive moisture largely arises from the fact that the soil is in a water-logged condition. It is well worth the extra trouble, after the erection of the concrete and brick foundation, to dig out the interior to the depth of 18ins. or 2ft. Then fill in this space with broken bricks, etc. In such a frame the evils associated with damping and mildew would be much less prevalent even when the weather conditions were very unfavourable for a considerable time. S. L. B.

WHAT OUR READERS SAY

BRAMLEY'S SEEDLING APPLE IN DENMARK.

SIR,—After many trials of various apples in Denmark, the English apple, Bramley's Seedling, has been found to be the most prolific for export purposes. It seems to be especially suitable for exposed positions in Jutland (Denmark), where it is being grown on heath ground, behind the shelter of firs planted some years ago.

The greater part of the soil of Denmark is suitable for fruit growing, but it has not been used for that purpose, for fruit to the amount of £5,500,000 (99 million kroner) has been imported during the last ten years. In 1918 an experiment was tried on one of the poorest soils in the country, that of the heath ground of West Jutland, which is subject to the severe winds from the sea. The trees were planted behind the firs, in passages, 20ft. to 40ft. in width, holes being dug 1yd. in diameter and depth, which were filled with old manure and soil. These trees yielded fruit in 1923, at the rate of nine apples to each tree. In the two following years the average yield was 27lb. per tree; and in 1926 there was an increase to 30lb. for each tree.

A record has been kept during the last few years by Mr. Hansen of Varde, of twelve districts of Jutland, which is published every year. It has been proved that the many small-holders who have added orchards to their holdings have been amply repaid, hedgerows and heath ground being used for this purpose. In the course of nine years Bramley's Seedling has yielded 260lb. per tree in other districts. Even on a small island off the coast, which consists chiefly of sand dunes, the experiment was tried fourteen years ago; the accompanying picture shows the size of the tree.

According to the statistics, in 1924 twenty-two trees yielded about 8,000lb. of apples, which were sold at the rate of 25 öre (at that time about 3½d.). This year the outlook is good, and the yield promises to be a prolific one, one grower expecting to make 60,000 kroner (£3,000). Of the various other apple varieties that have been tried none has yielded such good crops as Bramley's Seedling.—E. A. KOFORD, *Sentofte, Denmark.*

APPLES FLOURISHING IN A PINE WOOD IN DENMARK.
This variety is Bramley's Seedling.

WANTED: THE NAME OF AN OLD SINGLE CHRYSANTHEMUM.

SIR,—Having been much disappointed in modern varieties of single chrysanthemums, I am trying to trace the stock of an older variety. The latter was known to the writer at Wallington, Surrey, about 1906. The flowers were small, less than 2ins. in diameter, very firm, with a single, even row of ray florets; mahogany chestnut in colour, very fragrant and quite hardy. Has this old variety been lost, or can any reader of THE GARDEN help?—G. A. RUSSELL, *Radlett, Herts.*

[It is a somewhat difficult matter to name a chrysanthemum after a lapse of over twenty years, inasmuch as very few varieties then in vogue are now in cultivation. We cannot call to mind one answering the above description, nor have we any clear recollection of any single sorts noted for their fragrance. The one which had a perfume resembling that of a violet, named Progne, belonged to the reflexed Japanese, a section little known to-day, and this was grown thirty years ago, but it was a mid-November flowering sort. When singles were first introduced, most of them had only one row of florets, and though many of them were very pretty, they were superseded to a large extent by those possessing overlapping and double rows of florets; consequently, quite a number of the early sorts were lost. The only single chrysanthemum of modern sorts we are acquainted with, which appears to approach the one sought after by our correspondent, is Firebrand, a chestnut crimson, which

Digitized by Google

only grows about 3ft. in height, and blooms in September, and is best grown in sprays. It is, we believe, stocked by Mr. H. J. Jones of Lewisham.—ED.]

A SMALL LILY POOL.

SIR,—Possibly the enclosed illustration of a small lily pond may be of interest to readers of THE GARDEN, as it has been particularly successful this year. The lilies are Nymphæas pygmæa alba and p. helvola.

The illustration is rather deceptive, I think, as the pond is only 3ft. by 2ft. 6ins. and about 15ins. deep—not quite deep enough. I dug a hole the necessary size, laid in about 4ins. of concrete in the bottom with a sort of basket formed with reinforcing wire-work roughly the shape of the pond. I then placed an old galvanised iron bath in the centre filled with bricks to keep it in position, and then rammed in concrete all round the sides. When the concrete was set I removed the bath and smoothed the bottom and sides with cement and sand. I mixed a small quantity of "Pudlo" with both the concrete and cement mortar, and the result was a perfectly watertight monolith pond.—J. W. DENINGTON, *Croydon*.

A MINIATURE LILY POOL IN A READER'S GARDEN.
The lilies are Nymphæas pygmæa alba and p. helvola choice species for a small pool.

NEW MEADOW SAFFRONS.

SIR,—This autumn there have been sent out several new hybrid meadow saffrons, or colchicums, these being the result of the hybridisation of C. Bornmuelleri and C. giganteum or C. speciosum. Of the set I acquired three, in order to test their value and distinctness. The first to bloom was one called Daendels. When it first opened it was disappointing, its colour was rather pale and its size gave no real indication of its after dimensions. In a few days, however, one's verdict of its merits had to be rectified. The flower became very large and tall, even compared with the finest of the other meadow saffrons, and the colouring, a fine ruby purple, was very striking. C. Daendels flowered early in September. It was followed a little later by C. Rubens, which, from the beginning, inspired admiration from its size and the brilliant ruby of its large and handsome cups, which had white centres. Last of all came C. Lilac Wonder, which is a good large flower of a deep lilac. Its most striking feature appears to be its tendency to display additional segments. This varies in the different blooms, but some of these segments come rather deformed, which detracts from the beauty of an otherwise fine large meadow saffron. The colour of Lilac Wonder may be described, as already mentioned, as a deep lilac. In all there are about a dozen of these new hybrids, and should the others be the equal of these three they will be of considerable value in the garden in autumn and are probably the precursors of still finer meadow saffrons.—S. ARNOTT, *Dumfries*.

MAKING A PRIMROSE BANK.

SIR,—Perhaps some of your readers may be interested to hear how a primrose bank was made in our small town garden. A flowering currant had taken up a space of ground with its lower branches; these I cut back, shaping them irregularly into curves. Some old tree roots, logs, leaves and rubbish made a good sloping pile round about the currant, well filled in and stamped down with rotted leaves and manure. Six inches of good soil roughly sieved with a little bone meal and sand I put over all, then planted the primroses thickly from the bottom to the top. Whatever else has suffered, primroses have revelled in this wettest of seasons. Divided in the spring, they have spent the summer in shady corners of the garden, and are fine plants, the strong buds already showing colour. Half a dozen small ferns and a few anemones which wandered from the woods with them and are brave enough to grow in the town keep the primroses company; while clumps of snowdrops and some Campanula pusilla (blue) will afford a little variation of foliage. Now I am looking forward to seeing my primrose bank in flower beneath the pink-tipped branches of the sheltering currant. This bank will make a charming picture during early spring.—S. R., *West Hartlepool*.

HOW TO GROW CURRANTS

These bush fruits can be grown by every amateur even in quite a small garden, for they are of easy culture and do not need a great deal of attention.

Black Currants.

THE black currant will grow in almost any soil provided it is sufficiently open to permit vigorous root action and is retentive of moisture. It prefers a good deep loam and a cool place. The ground for planting should be well trenched and manured with horse-manure. Planting should be done in autumn, though it may be left till the turn of the year. Young bushes should be purchased and planted 6ins. deep in rows 4ft. or 5ft. apart with 4ft. to 5ft. between the bushes, and cut back to within two or three buds of the base at the time of planting.

In the first year from planting all bushes which have not made three shoots or more of 2ft. in length should have their growths shortened to two eyes. Those which have made three growths of 2ft. should have the weaker shoots—*i.e.*, those under 2ft.—cut back to two eyes. In later years pruning consists in cutting right out the less vigorous growths that are formed, thus allowing the development of new vigorous shoots, on which the finest fruit will be borne. The black currant is a gross feeder and should be mulched with manure in alternate years. During the growing season hoe freely.

Varieties.

Certain varieties do better in some localities than in others, and I should suggest to those readers who are desirous of obtaining the best results to make enquiries as to tried varieties in their particular locality. The following can be recommended: Baldwin's Black, Seabrook's Black, Boskoop Giant, Goliath, Daniell's September.

Propagation.

Black currants may be propagated from cuttings of well ripened growths 10ins. in length, taken at the time of pruning, *viz.*, October or November. The cuttings should be obtained from healthy, vigorous bushes, and should be the size of a pencil or larger. Propagation from healthy stock is of special importance, as one of the worst diseases of black currants—reversion—is transmitted by propagating from bushes suffering with the disease. The ground for planting the cuttings should be thoroughly well dug and the cuttings inserted 6ins. apart in the rows with 2ft. between the rows. They should be inserted so that the three top buds are above the surface of the soil, which should be well firmed after planting. During the following spring and summer the ground between the rows must be hoed to conserve moisture and to prevent the growth of weeds.

The bushes should be ready to plant out one year from the cutting.

Pests and Diseases.

Without doubt the worst pests attacking black currants are the big bud mite and reversion. The former is due to an insect which attacks the young developing buds, causing them to develop to at least twice their normal size and to become almost globular in shape. These buds rarely develop, but shrivel and die, with the result that the possible crop is considerably reduced and, in the case of a bad attack, may be *nil*. On a small scale, hand picking should be resorted to and the gathered buds immediately burnt.

The cause of reversion is still obscure, but the symptoms of the disease are easily recognised by the change in the form of the leaves, reverted leaves having fewer sub-main veins and fewer points than the normal leaf, while the margins are more deeply serrated but have fewer teeth. The flower, too, is shiny and of a purplish colour, while the normal flower is covered with downy hairs. The flower buds do not carry fruit and, consequently, the crop fails. Badly attacked bushes should be uprooted and burnt, while cuttings should never, under any circumstances, be taken from "reverted" bushes.

Red and White Currants.

These may be propagated from cuttings as above, but all buds except the three top ones should be removed from the cutting before planting. Bushes should have 6ins. of clean stem showing above the ground. This class of currant prefers a rather lighter soil than the black, and is not so gross a feeder.

As the red and white currants fruit on spurs, their pruning is quite different from that of the black. A bush having six or seven main branches distributed evenly in the form of a cup should be aimed at. This can be obtained by hard pruning for two or three years until the requisite number of branches are formed. Subsequent prunings consist in cutting main branches to an outside bud, leaving 6ins. of current growth each year and spurring laterals to one or two buds. The bushes repay an annual top-dressing of artificial manure in spring.

Varieties.

Red.—Raby Castle, Scotch, Fay's Prolific, Perfection, Victoria.

White.—Cut-leaved White, Grosse Blanche, White Dutch, Macrocarpa. H.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

NOVEMBER was the accepted time for planting fruit trees in Scotland, but no such limitation is observed to-day by nurserymen or growers. Provided the weather is open and dry, fruit trees and bushes may be put in any time during the next four months with no more risk of injury than if they had been planted early in the season. The late Mr. David Storrie considered that the best time to plant was from mid-November to Christmas, but unless conditions were favourable he advised that operations be deferred until spring. While Mr. Richard Steward also favours November, he admits that he planted apple trees in June, and they were as fresh and as green as those which were planted in autumn. In any case the recognition of the calendar month is unreliable as a guide, for the obvious reason that the condition of the trees must regulate the period when transplanting may be safely undertaken. Defoliation depends on the season, and as the process is earlier in certain years and later in others, a fixed period in autumn cannot be defined with any degree of accuracy. The belief, however, is general among experts that the earlier the trees are planted after the fall of the leaf the better, because trees then planted will throw out a certain number of new rootlets before winter and thus be prepared to make an early start into growth when spring comes. That rootlets are thrown out in this way was established in the Woburn experiments by lifting the trees again before winter was over. Out of forty-two trees representing apples, pears and plums, twenty-nine were found to have formed a more or less considerable output of rootlets before the middle of January. Trees lifted and planted in another part of the garden are not influenced by disturbance to the same extent as those obtained from a distant nursery, as they are not so liable to receive a check when lifted with a ball of soil attached to the roots and transferred immediately to their new positions, and the operation may, therefore, be carried out now even although they are not denuded of their leaves. Established fruit trees and bush fruits benefit by an autumn dressing of artificial manures applied in the proportion of 4 oz. of basic slag and 1 oz. of kainit per square yard as far as the roots extend, but to obtain the full benefit of this treatment it should be supplemented by 2 oz. of superphosphate and 1 oz. of sulphate of ammonia in February or March.

I sometimes wonder why seaweed is not in more common use in gardens located near the coast, for there is a manurial value in the salt and potash which it contains. Vegetable crops such as peas, beans, leeks and celery respond to its presence in the soil and farmers testify to its helpful effect in the cultivation of potatoes. It is their practice at this season to scatter it over the fields, where it is allowed to rot preparatory to ploughing, but for garden purposes it may be applied in other forms. In some parts of Scotland, and particularly in the Western Highlands, the material is burned in the same manner as garden rubbish and the residue incorporated with the soil at the rate of 4 oz. to the square yard. That process is best adapted to localities where supplies are plentiful, and requires careful management if waste is to be avoided. An alternative and perhaps better system of treatment consists of mixing the seaweed with animal manure and keeping it stacked for a few months. When this is done in autumn the material will be decomposed by the time digging operations are begun and, being in a soft condition, it will the more readily mix with the soil and provide the humus which is necessary to satisfactory crop production.

Hedges are a perplexing problem for the occupants of the numerous housing schemes that are now dotted all over the length and breadth of the land, and as privet apparently forms the only solution, there is a monotonous similarity in the boundary and lay-out of the gardens that is only equalled by the houses. At the present time privet is one of the best selling lines in the trade, and although the nursery trade is devoting increased areas to its propagation, stocks are cleared out annually and invariably before the season is over. The only justification for privet is cheapness and rapidity of growth, and for these reasons it continues to find favour with the multitude in preference to thorn, beech or the more ornamental hedge. All these subjects may be planted in autumn or in early spring, and except where the land is wet, the hedge should occupy a flat site. Dig the ground deeply or, better still, trench it to a depth and width of 2ft. or 3ft., covering the bottom with a thick layer of garden rubbish and mixing chopped turf and leaves with the upper spits. Let firm planting be the rule, and as privet has a bad reputation for robbing the soil of nourishment, allow ample space between the site of the hedge and the nearest occupants of a flower border. Privet that was planted last autumn or spring should now be cut back to within 6ins. of the ground so that the hedge may form a strong, dense base.

As garden crops of potatoes are safely stored by this time, attention can now be devoted to the tubers that have been selected for seed. Go over them carefully, remove any soil that may still be adhering to the skin or filling the cavities at the eyes, and discard any specimens that show the slightest indication of disease. By sprouting the seed before planting the weight of the crop can be materially increased, and as the process is a simple one, amateurs should not hesitate to give it a trial. Any shallow box is suitable for the purpose, and all the labour involved consists in arranging the tubers in such a position that the end containing the largest number of eyes is placed uppermost so that they may be exposed to the light that penetrates any frost-proof outhouse. ST. MUNGO.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful and interesting hint sent in by a reader. Five shillings will be paid for all others published. Payments for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF-GUINEA HINT

Preserving Begonias.

When the garden beds are cleared for the winter many people who do not possess even an unheated greenhouse throw away the begonia tubers under the impression that they cannot be kept and grown again the following year without the aid of glass. This is a mistaken idea.

Take the tubers up as soon as the frost affects the leaves, leaving them in a dry, sunny place until the succulent stalks have died off. Put them away, after removing all adhering soil, in a damp-free place until January. They may then be put in a box full of bulb fibre and *placed on the kitchen rack* every night and, if possible, near a sunny window during the day. They will show growths very quickly and will be quite happy until they are large enough to be potted in April and planted out at the beginning of June. Treated in this way they may be kept for years.—G. H.

Storing Root Crops.

The main principles of preserving root crops are, first, prevent sweating; second, exclude wet; third, keep out frost; fourth, prevent roots growing. To prevent sweating, openings may be left at the top of a pile of roots, or, when the pile is half built, a little clean straw, that is quite dry, in bundles, may be introduced. To keep out wet, see that good covering is provided. To keep out frost, use extra covering in severe weather. To prevent roots sprouting, cut away close to the crown, and keep them as cool as possible. While parsnips and carrots will stand close cutting, other roots will not tolerate cutting to the quick.—A. J. J.

A Frame for Cuttings.

It is not altogether satisfactory to strike cuttings in open ground, and where pots and frames are scarce this hint will be found very useful. Knock the bottom out of a large, strong wooden box, preferably one 18ins. deep. Place this in any partially shaded place (but not under the shade of trees). In the bottom put 6ins. or 7ins. of clinkers, and on the clinkers a good layer of leaves to prevent the soil getting into the drainage. Then fill the box, to within an inch or two of the top, with sieved soil and sand. Make fairly firm and put a layer of sand on the top. If the sun is hot at first, shade with newspapers supported on canes stuck in at the corners of the box. Cuttings will strike readily and can remain in the frame until next spring.—K. L. J.

Roses from Cuttings.

Having been most successful in growing roses from cuttings, I think it would interest your readers to know my method, as October, I find, is quite a good month for the work. Cuttings of fully ripened wood are taken, about 8ins. long and stout in character. See that the heel of older wood is neatly trimmed and no frayed edges left; and lastly—and to this I attribute my great success—see that the *top of cutting* is *cleanly cut* with a sharp knife just above an eye, as carefully as in pruning roses, so that no snag of wood remains that has no suction power, as it invariably rots and causes the die-back. Plant two-thirds of length in ground which is well mixed with sand, tread firmly in and make surface loose, and then success is assured.—R. G. L.

Preparing the Ground for Sweet Peas.

I am invariably congratulated on my show of sweet peas, both for size and quantity. During October I dig a trench at least 3ft. deep and fill with vegetable refuse—potato peelings, cabbage and lettuce leaves, fruit skins, etc. Occasionally cover with a small quantity of soil, and when 12ins. from the top fill in with fine light soil. The result will amply repay for the extra trouble involved.—R. B.

THIS MONTH IN THE GREENHOUSE

Potting Spiræa japonica for Spring Flowering.

THIS delightful spiræa, or astilbe, is such a charming subject for the embellishment of the cool conservatory or decoration of living-rooms during the spring months that everybody with the means at their disposal should grow a few plants of it in pots for the purposes mentioned.

During October will be found a suitable time for potting up the roots, and clumps may either be lifted from the open ground or purchased from any nursery man. They are obtainable at such an extremely modest price that, unless good strong plants are available from the open garden, it is better follow this latter plan.

The clumps should have the long ragged roots trimmed off a little before they are potted in pots just sufficiently large to hold them. As a general rule 5in. and 6in. pots will be found large enough.

Use a compost consisting of loam, leaf-mould, sand and a little dried cow manure—the whole to be passed through a ¾in. sieve. Pot firmly and allow ample space for watering, taking care that the crown of the clump is left above the level of the surrounding soil.

After potting, water with a can fitted with a fine rose and plunge the pots to the rims in ashes or sand out in an open, sunny position, or if very early flowering is desired, a few pots may be stood in a cold frame, the lights of which must be left off on all suitable occasions. See that the plants are neither allowed to become too dry, nor sodden, through too little or too frequent watering.

Very quickly young roots will begin pushing out into the new soil, and at this stage the plants may be introduced to the protection afforded by a cool greenhouse, or if a succession is required, the most forward may be treated thus and the remainder left outside to be brought inside at intervals as desired.

They may be quite successfully cultivated in any light, frost-proof position, but for very early work they may be removed to a warm house after about a fortnight in the cool greenhouse and then back again to the greenhouse so soon as the flower spikes commence to show colour.

The cultural details are of the simplest, all that is necessary being an abundant supply of water at the roots, and immediately the flower spikes commence to show every alternate watering should consist of diluted liquid manure, varied occasionally with a little Clay's or some other good proprietary fertiliser. Damping the stages between the pots is highly beneficial, but the greatest care must be exercised that no water is allowed to get on the foliage, for this is very quickly scorched, and in a well grown plant the foliage is almost as beautiful as the flowers themselves.

Both pink and white varieties of this useful plant can be obtained, and after they have finished flowering they should be stood in a cold frame until all danger of frost is over and then planted out in a moist position in the garden, where they will yearly increase in beauty.—T. H. E.

Salpiglossis for Conservatory Decoration.

A GROUP of these highly ornamental and attractive half-hardy annuals makes a striking display in the conservatory. Plants from seed sown during October or November will, under cool greenhouse culture, bloom profusely in the following spring. Sow three seeds in a 6in. pot in a rich compost of three parts loam, one part leaf-mould and one part old decayed manure. Crock the pots well, fill up with the compost, and dibble three seeds into the compost in the centre of the pot about ½in. deep and cover with the soil. Stand the pots on a shelf or staging and cover with paper, after having watered the pots. When the seeds germinate remove the paper, giving the seedlings as much light as possible. When about 2ins. high remove the two weakest seedlings, leaving one as near the centre of the pot as possible. Grown on in a cool condition, only excluding frosts, handsome flowers will be obtained in the spring. The varieties atro-coccinea, dark scarlet; coccinea, orange-red; Kermesina, crimson; lutea, yellow; rosea, rose; violacea, violet-purple; and superbissima, a strain of very large flowers with golden yellow marks on the petals, all grow to a height of 2–2½ft., but there are also dwarf strains which only grow to 15ins. high and are of various colours. They make an interesting and uncommon group for the conservatory.—M. H. G.

A Decorative Greenhouse Climber.

Plumbago capensis (*Leadwort*).

THIS is an ideal plant for the wall of a cool greenhouse—a structure from which frost is just excluded. It is quite easy to grow in an ordinary pot-plant mixture, and quite simple to train to wires for support as growth develops. When the space is covered an annual cutting back or spurring back is necessary. There are white and blue types—the latter being most in demand and, of course, more showy. Cut portions stand well in water and are delightful for table decoration, for which purpose the writer has many times used it, alone and in conjunction with that splendid salmon pink geranium Mrs. Lawrence. This latter is a really beautiful combination for anyone to note who may be seeking such. Pot plants of plumbago of 2ft. or so high make useful "dot" plants for summer bedding, but small groupings are better, being more effective.—C. T.

PLUMBAGO CAPENSIS IS AN EXCELLENT PLANT FOR WALL DECORATION IN THE GREENHOUSE WITH ITS ATTRACTIVE CLUSTERS OF BLUE FLOWERS.

Winter-Flowering Pelargoniums.

THE plants, having been fully exposed all the summer, will have their growths well ripened by now, and arrangements should be made for placing them under glass, choosing a light and dry position, the stage near the front ventilators being very suitable. By placing some of the best shaped specimens on empty inverted flower-pots, the attractiveness of the group will be enhanced; and by keeping the leaves of each plant just clear of its neighbours so that air freely circulates between them, they will remain in a healthy, free-flowering condition for a long time. The pots being well filled with roots, feeding will be necessary to maintain vigour. Weak soot-water, liquid manure and a reliable proprietary fertiliser in small doses may be used in turn to produce the desired effect. Remove all flowers as they begin to fade, also yellow leaves; there will not be many of the latter if proper care is taken in giving water in sufficient quantity only to meet the plant's needs. When first taken indoors, it is important to give plenty of air, and for a time the ventilators may be left open night and day when the weather is favourable. Later, when cold and damp have to be guarded against, maintain a minimum temperature of 55° Fahr.; but with sun heat the thermometer may rise to 65°, when free ventilation must be given. The admission of air must at all times be regulated by the temperature, bearing in mind that excessive fire heat is not necessary so avoid a close, stuffy atmosphere, which pelargoniums resent as much as they do cold draughts of air.—C. C.

Dicentra spectabilis.

THIS is a hardy border plant that gives unqualified pleasure when grown in pots, the graceful, drooping racemes of rosy pink, heart-shaped blossoms never failing to attract notice. In a temperature of 50° to 55° Fahr. it may be had in bloom in February, but without heat it is just as welcome, though one has to wait a little longer to realise its full beauty. Those with cold greenhouses will, therefore, be well advised to pot a few plants this autumn. During October is a suitable time for potting the clumps which may be obtained from most nurserymen. The plants are great moisture-lovers and should be grown in good loamy soil with plenty of drainage in the pots. After potting they may be allowed to stand at the foot of a wall or in a cold frame and kept supplied with water as required to keep the soil moist. They may be brought into the greenhouse in December and given a light position near the glass. As the foliage develops, care must be taken not to let the soil get dry, and when growing freely copious supplies of water will be needed. The need for well drained pots is, therefore, obvious, for, unless provision is made for the escape of superfluous water, the soil will become sour and the plants unhealthy, even if they survive. Their period of beauty is a long one, and from the appearance of the fern-like foliage to the passing of the blossoms, interest in the plants is sustained. After flowering return the plants to the border: they will not be suitable for forcing the following winter. I should have stated that weekly applications of liquid manure will be of great assistance when flower buds are forming.—J. C.

FRUIT AND VEGETABLES

Open Wall Fruit Trees.

JUST now is a good time for preparing stone fruit trees for an application of lime. Year after year some specimens are unsatisfactory because they do not fruit well. There may be plenty of blossom, but few fruits set and come to maturity. Most likely the ingredient in the soil that is lacking is lime. If so, remove the surface soil a little, but do not bare the roots, and apply about 1 peck of lime per tree. I am now referring to established trees. New fibrous loam should be placed on the lime in preference to the old, in the case of special trees. In a very short time a network of roots can be obtained near the surface, and then it is a great pleasure to the cultivator to feed and mulch such roots and, in due course, to gather the fine crops of fruits Maturing leaves should be got rid of by forcible syringing, which also cleanses the trees of insects. Cut out any dead branches found, and brush up the leaves, burning all of them forthwith. The trees will thus be prepared for their winter treatment—pruning, tying, etc. Note vacant spaces for new trees.—G. G.

Timely Notes on Artichokes.

GLOBE artichokes are quite hardy when grown in light, well drained soils. It is the surrounding moisture, almost of a stagnant nature, that ruins these plants in heavy, retentive ground; when frosts come the plants suffer more. In every case it is advisable to clear away all decayed and fading leaves and foreign matter, weeds included, from the base of each plant, now. Instead of waiting until next spring before applying any top-dressing material, I like to add it early in the autumn, soon after the plants have received their cleaning, and then put on, as a protecting mulch, dry litter over some dry tree leaves. Next year, plants treated in this way will be much stronger than neglected specimens. Jerusalem artichokes may be left in the ground all winter, but I advise the cultivator to lift a portion of the crop, grade the tubers into two sections, one for cooking and the other for replanting again next spring. The tubers should be stored in dry sand; if stored under straw only those for eating become dry and the planting tubers lose freshness and strength. Some tubers may be left in the soil throughout the winter, being lifted as required. These plants are very deep rooting, and thrive best in a light open soil. The present is a good time to get the soil trenched, at least 30ins. deep, in readiness for next spring. The Chinese artichokes should be used as required, direct from the ground.—HANTS.

Roping Onions.

WHERE onions cannot be stored thinly, by reason of lack of space, they should be tied in bunches or roped. A simple roping plan is to tie the onions tightly to a stout stick so that the air can reach practically every bulb. A stick 2ft. or rather more in length will take nearly half a bushel of onions. A large quantity can successfully be stored thus in a small space. The onions should have been pulled two or three days before roping. Tie to the stick in bunches. The ropes should be hung in the sun for a few days and then be transferred to a cool, airy place, where there is little danger of frost penetrating. The onions should then keep well.—A. J. J.

Manures to Apply in Autumn.

THE usual advice in gardening is to apply or use "rotted manure," but that is not altogether correct when it comes to the application of manure in autumn. Fresh manure should be employed in preference to any other, because decay proceeds in the ground during winter and the stuff is reduced to humus by spring. An average dressing for intensive gardening is one load to 4 or 6 rods. Leaf-mould not fully decayed, fallen leaves and organic refuse like shoddy, waste fish, horn meal, leather shavings, etc., also decay into good humus if applied soon. We may add here that some such natural manure is always required for a garden soil in order that its humus content may remain at a high standard. Slags are among the most important artificial manures to apply during this and next month. These slags supply the all-important phosphate and lime which crops and soils require, and their use is extremely beneficial for all fruits, flower borders, turnips and others. Quality, expressed in percentage phosphates, controls the price and the quantity to apply; 3-4 oz. of the best and 6-7 oz. of the cheaper grades may be looked upon as limits; this works out at about ½ stone to 1 stone per rod. Potash especially in light soils and where fruits are grown, may usefully be applied at 3-4 oz. per square yard, between now and the New Year in the form of kainit or potash salt; these tell better then than when applied later. Rock phosphates which have been "pushed" by several firms since the war, are excellent fertilisers for all soils, yielding up the requisite phosphatic matter which all plants need; at 4-6 oz. per square yard, applied soon, they "till" fine. Lime, so necessary to keep plants and soils in the pink of condition, is also applied in autumn or winter. Ground lime (½ to ½), quicklime (½ to ¾), slaked lime (1), acetylene refuse (1 to 1½), are the common kinds of lime in use, the numbers giving good dressings in lb. per square yard. In all cases must these autumn-applied manures be worked into the soil; natural manure and manure substitutes can be forked into the upper spit; artificials are best raked in or lightly forked in, because they have, in all the above cases, to undergo changes which can only take place in a fairly intimate admixture of soil and fertiliser. Autumn manures become, in this way, available for plants by the spring cropping time.—H. H. A.

Eradicating Vegetable Root Pests.

MANY of the pests which infest our vegetables in summer spend the winter in the top spit of soil, quite close to the spot where they passed their destructive existence. As the ground is vacant at that time we can, however, apply a strong chemical or fumigant, in order to eradicate the pests and at the same time to go a long way towards guaranteeing pest-free crops next year. Mix together 1 stone of lime and 1 lb. of crude naphthaline, obtainable from gasworks and from chandlers; scatter this over the surface at the rate of ½ lb. to 1lb. per square yard and fork it in practically at once. Not only does this kill the pests by gassing them, but the lime proves beneficial in many ways. Carbolic acid, ½ oz. in 1 gallon of water, is also a fine fumigant where liquids are preferred; the ground is forked over first and then fully wet with the liquid, at some 3 square yards per gallon. Cresol disinfectant, 1 pint in 8 to 10 gallons, is also first class when used in a similar fashion; household ammonia at the same rate is good and other liquids at similar dilutions can be employed. In each case get cheap, nasty commercial quality and use it fairly freely. Deep digging or trenching, where the surface soil is buried deeply, is also quite effective in eradicating such pests, because when they are put well under the soil they cannot come to the surface again. When the ground is but lightly forked over, it may be possible to let the hens have access to the fresh soil and they can account for large numbers of pests. The old adage that "Prevention is better than cure" applies with great force in this connection for, if nothing be done, the pests will appear next year in ever-increasing numbers.—H.

OUR SERVICE BUREAU

Getting Rid of Tree Stumps.

In digging over my new back garden, which until recently was a meadow, I came across the stump of an elm tree just below the surface. It has sent up several new growths, which shows it has only just been covered.—J. B., East Dulwich.

By far the quickest way to get rid of the stump of a tree is to burn it up in the following way: With an augur bore several holes as deeply as possible in the stump. All the holes are then filled with paraffin. As the oil soaks into the wood the holes are refilled, and this is done on several occasions. After three or four days the stump will, to a large extent, be heavily impregnated with oil. Now collect a quantity of dry stuff and pile this lightly right over the stump. Set the mass alight and soon the oil-soaked stump is blazing away merrily. The burning process will go on for some time, and in the end the whole of the stump and most of the roots will be reduced to ashes. It will now be quite a simple matter to clear the ground, and the ashes which have come from the burning of the stump should be scattered over the ground and dug in on account of their fertilising properties.

Culture of Hippeastrums.

Will you please tell me the correct treatment for hippeastrums. Mine have flowered well last spring and are now being dried off. Should they be repotted and, if so, when, or is it best not to disturb the bulbs?—A. M., Leatherhead.

As your hippeastrums dry off you should stand them in a cold frame or cool greenhouse, where they will be fully exposed to the sun. During the resting season a temperature of about 45° will suit them. If they are in good condition at the root it will not be necessary to repot them, but they will require to be top-dressed with some fresh compost. When you do repot them, it is best done when you start them early in the year. They should then be shaken out and all decayed roots and the base of the bulbs cleaned before repotting. After repotting water must be very carefully afforded until they have made a quantity of new roots and have started into growth. Overwatering at this stage is responsible for many failures.

Treatment of Gladioli After Flowering.

Would you kindly advise what treatment gladioli require after flowering so as to secure good-sized corms for next year? When should gladioli seed be sown, how long does it take to germinate, how soon would the seedlings reach a flowering state, and is there any advantage in raising them from seed?—A. W., Colwyn Bay.

During October, lift the stems and corms of the gladioli and place them intact in boxes or on the floor of a cool, dry shed. Directly the stems will readily part from the corms, store the latter in paper bags and replant next March and April. Sow gladioli seed about the same time outside, but earlier if in boxes under glass. The second year the corms of the strongest plants will produce flower spikes freely. Corms are now so cheap that the purchase of such is the best method. A batch of seedlings, however, is interesting and also useful.

WATERER'S NEW APPLE 'JOHN WATERER'

AFTER exhaustive trials at our Twyford Nursery we have proved this an apple of outstanding merit. It bears heavy crops of exceptionally large fruit—we have gathered apples weighing up to 2lb. 2 oz. each. It is a fine, free, shapely grower and has the advantage of being equally excellent as a standard, bush, cordon or trained tree. It is a first-rate cooking variety, keeps well into May, and its great size and shape, which cause such little loss in peeling for cooking purposes, will make it a grand market apple. As one of the apples of the century we have every confidence in recommending it and are sure that on the exhibitors' table it will in future take a very prominent place.

PRICES:	each
Maidens	2/-
Bushes, 2 years	3/6
,, 3 years	6/-
,, 6 years	10/6
Fruiting Cordons ..	7/6
Fruiting Horizontal-trained 2, 3 & 4 tier	10/6, 12/6 & 15/-
Fruiting Standards ..	12/6

We not only supply every kind of fruit tree in endless variety, but also advise regarding soils and localities. Please write for a copy of our Illustrated Catalogue, a guide to fruit culture in itself. We will gladly send you a copy post free.

THE GARDEN

VOL. XCI.—NO. 2917. OCTOBER 29, 1927. PRICE TWOPENCE.

TULIPS FOR SPRING BEDDING

A few ideas on how to make the most of any tulip plantings that are being carried out at the present time. These suggested arrangements are certain to add novelty and beauty to your garden next spring.

A PLEASANT spring garden entails a great deal of forethought and much careful preparation, so that it is during the autumn months when plans for the spring-time floral display will be carried into effect. Tulips of the Dutch and Darwin types, as well as those of other persuasions, lend themselves to much delightful harmony when used with other spring-flowering subjects or when congenially blended, and the bewildering array of colour exhibited by these bulbs is certainly worth the trouble of harmonising into some pretty effects. A pink variety, such as Clara Butt, or an almost scarlet tulip, such as Mr. Farncombe Sanders, is very lovely when poised over a groundwork of the grey-foliaged Stachys lanata or when carpeted with a pale aubrietia like the variety Lavender; a low wall draped with these fascinating alpine plants forms a pretty background to a tulip border. Darwin tulips grouped under and around lilacs play their part in creating a delicious spring-time picture and one redolent of old English gardens.

Myosotis and Cottage Maid or Rose Gris de Lin is a happy blending, or, as an alternative, the double white arabis may supplant the forget-me-not. A rather nuusual but an undeniably pretty planting is golden alyssum (A. saxatile) and either an orange or a mauve tulip. Yellow polyanthus primroses make a delightful foil for either Thomas Moore or Fred Moore tulips, the bulbs planted rather thinly, and a decidedly *bizarre* and vastly entertaining arrangement is one of mixed polyanthus interspersed with mixed early-flowering tulips—bright and cheerful, if not exactly æsthetic.

The red-purple Darwin Frans Hals is of striking mien when towering over a carpet of the popular Maggie Mott viola; and another exquisite effect may be obtained from the use of this viola and a yellow tulip. Cerastium tomentosum is a lovely setting for the purple Darwin Morales or the almost black La Tulipe Noire; and a mauve phlox (divaricata) is pleasingly associated with a pink tulip.

All-tulip combinations are almost endless but, nevertheless, command much careful thought if pleasing results are to be assured; a few suggestions are the yellow cottage Tulip Mrs. J. Robertson with the dusky Darwin La Tulipe Noire or with the purple Darwin Morales; the Darwin Wm. Copland and the cottage Walter T. Ware, a blend of lavender and rich yellow; Clara Butt (Darwin) of soft pink colouring and the cottage variety Ellen Willmott, pale yellow; the cottager Orange King and one of the Darwins Night or La Tulipe Noire; and the rosy red Professor Rauwenhof, a Darwin, with one of its darkest *confrères*, such as Zulu or Night.

A few early tulips happy in collaboration are Chrysolora and Prince of Austria, or Chrysolora and Dusart; White Hawk and Couleur Cardinal, striking but beautiful in white and almost scarlet; the violet President Lincoln and Yellow Pottebakker; the orange Fred Moore and either of the yellows; Couleur Cardinal, Vermilion Brilliant or Prince of Austria with President Lincoln; and the delicately tinted pink and white Cottage Maid with Chrysolora.

A border of Darwin tulips planted in "blocks" of appreciable size is of noble presence, and with ordinary care the colour scheme is easily arranged so that blatant contrasts are nil. A bold massing of any one brightly coloured variety is always rich in character and of striking appearance.

Masonry or bricks may be made to play a useful part in effect—a scarlet or rosy red tulip is of pleasing appearance when provided with a background of grey stone; but a red brick wall calls for careful treatment, and here it will be wise to use the softer yellows, mauves and pinks and, perhaps, orange shades, and omitting scarlets, bright rose, etc.

Tulips should never be overcrowded when used with other spring-flowering plants; it is as "dot plants" arising from a floral carpet that they give of their best. In many instances it will be necessary to plant the "carpeters" first, a few weeks in advance of the bulbs, and the latter are easily inserted at a later date with trowel or dibber.

A closing hint is one of the large bicolor trumpet daffodils with a yellow tulip or mauve tulip, thus securing two successive displays from the same bed. Yellow or mauve tulips are suggested in order that the colours may suit the surroundings as did the daffodil.

The present time is ideal for carrying out all plantings of tulips and other spring bedding subjects such as wallflowers, polyanthuses and forget-me-nots. The soil is in good condition, and as the removal of the remains of the summer flowering plants is undertaken the gaps so created can be filled at will by planting choice spring flowers.

This Week's Work

For Gardens in the South and Midlands.

Lift and store gladioli and dahlias.

Prepare ground for planting herbaceous perennials, roses and shrubs.

Cut down globe artichokes and protect the plants with light litter.

Plant gooseberries and currants.

Prune and train Morello cherries.

Sow sweet peas in pots for greenhouse decoration.

Examine onions that are stored.

Remake lily of the valley beds.

Lift a few rhubarb stools and expose to frost before forcing.

Ventilate well and keep a dry atmosphere in the late vinery.

This Week's Work

For Gardens in Scotland and the North.

Lift early-flowering chrysanthemums.

Remove old shoots from loganberries and raspberries.

Lay in a stock of farmyard manure.

Transplant bush fruits.

Remove sweet peas that have germinated in heat to a cold frame.

Pinch tops of seedling wallflowers.

Continue planting bulbs out of doors.

Spray gooseberries that were attacked by mildew.

Root prune fruit trees where necessary.

Give Brussels sprouts attention.

Begin digging or trenching vacant ground.

Make a sowing of culinary peas under glass.

Digitized by Google

APPLES FOR THE SMALL GARDEN

It is hardly necessary, perhaps, to stress the fact that so-called "cheap" trees are generally "dear at any price," and that first-class material, true to name, from a reliable source, is alone worthy of garden planting.

AT this time of the year, which sees the opening of the tree-planting season, many intending planters are debating the choice of apples to plant in their garden.

Form of Tree.

Regarding the form of tree suitable for growing in the average garden—a form that will combine ease of management with economy of space and provide good fruit early, and late, in life, the bush-shaped tree is hard to beat.

Grown on dwarfing root-stocks, such as the Broadleaf English Paradise or, if the garden soil is strong and fertile, the Doucin Paradise, there is no difficulty in keeping the bushes shapely and within bounds, and planted not closer together than 10ft. from tree to tree each way they quickly come into bearing and make fruitful trees of lasting profit.

Bush trees on the crab or "free" stock are generally a most unwise choice. They make a lot of wood, encroach by branch and root upon neighbouring beds and, more often than not, become a nuisance in the small garden.

It is well to get the bush-shaped trees with a clean stem of 18ins. or 2ft., so that branches are well up off the ground—if only for the reason that it is very difficult to keep the ground clean beneath stemless trees.

For planting in the quite small garden, where even compact bush trees would find insufficient "elbow room," or to furnish the boundary fence or house wall, cordon and espalier trees will give every satisfaction. They can be grown in a space far too cramped to carry any other form of apple tree and with little encouragement bear high-class fruit with surprising regularity and in no mean quantity.

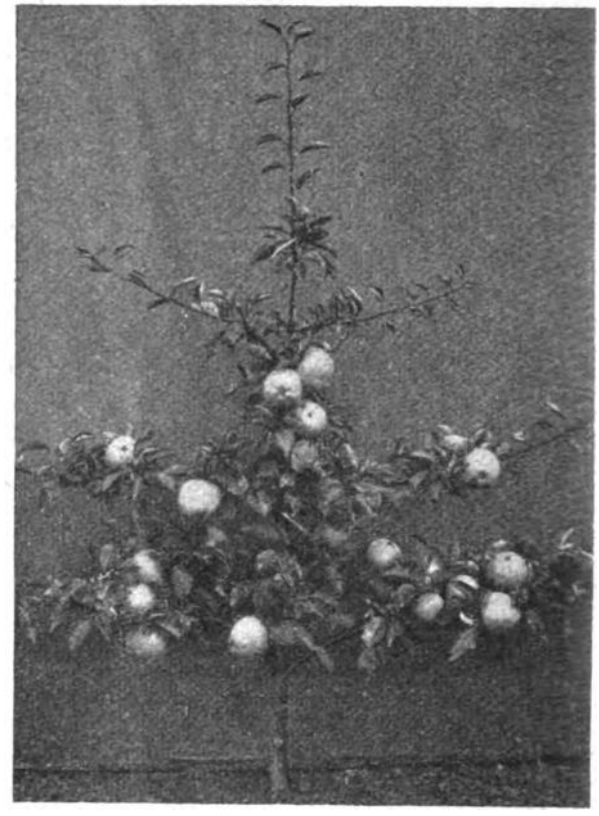
The single cordon, trained upright or obliquely, is a most convenient and exceedingly simple way of growing apples; and the wonder is that they are not more frequently planted than they are.

The low horizontal cordon is just as simple and efficient, and even more decorative in effect when trained to a wire run about 12ins. above the ground level along the pathside or border edge.

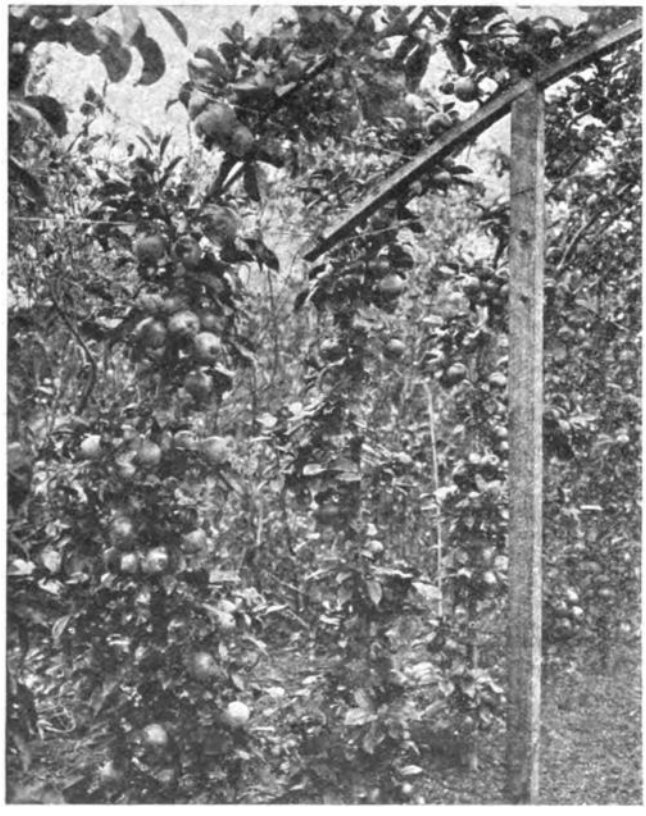
An added advantage of cordons—and the same may be said of low espaliers—is that they cast little or no shade, the root-run is restricted, and they interfere in no way with other plants near by.

Single cordons may be planted 2ft. apart, but the double and treble stemmed trees must be allotted more space in proportion. Here note that when the wall or fence is of but moderate height, cordon trees are best planted obliquely, rather than vertical, this angular planting permitting each tree to attain a greater length and preventing the growths "topping" the wall.

When planting espaliers—which, of course, consist of three or four tiers of branches ranging on either side of the central, straight stem—a common fault is to set them too close together. An allowance of 15 feet lateral space per tree looks a lot at planting time, when the trees are young, but certainly nothing less than this should be given, or the trees will soon crowd and spoil one another.



A YOUNG ESPALIER TREE IN THE PROCESS OF FORMATION.
Note how the laterals are being trained.



APPLE TREES TRAINED AS SINGLE STEMMED CORDONS.
The varieties are Cox's Orange Pippin, Allington Pippin, and Worcester Pearmain.

Few planters nowadays make the mistake of planting big standard trees in the garden (possibly because there are so many terrifying examples of this sort of folly the countryside over), these cumbersome, shade-throwing trees being rightly relegated to the grass orchard, where they do well. Occasionally, half-standard trees are the choice for the large garden, the clean, branch-free stem of 4ft. or so permitting the ground between and beneath the trees to be cropped with vegetables or "small" fruit; they being set at some 15ft. or more each way.

Regarding the age trees should be when purchased for planting, there is no getting away from the fact that one or two year old trees stand transplanting better than do older ones, and are less expensive to buy. The disadvantage of planting such young trees is that the all-important "foundation laying" then falls upon the gardener; and this is work requiring most skilful handling.

So that (except in the case of simple cordons, which can well be planted as "maidens" or two-year-olds, or where the gardener is experienced in the early shaping of young trees) it is generally best to get three-year-old trees for planting: which trees will be well formed, will quickly start to fruit and are fairly straightforward to train on. In the case of the somewhat complicated espaliers, if the little extra cost is of no great concern, get four-year-olds; then the framework of branches will have been properly laid by skilled nursery hands.

Selection of Varieties.

When choosing varieties the intending planter often goes astray.

The first thing is to find out which varieties do well in the neighbourhood, and which do *not*. Any information of this nature should certainly influence your final selection.

There are several varieties that seem to stand out as good "doers" in most districts, however, and a selection of these, to give a complete succession of good quality fruit, is not likely to disappoint.

The undermentioned are a few that do well in most gardens about the country, and thrive equally well in the bush, espalier or cordon form, whichever seems best to fit in with the site available and the general lay-out of the place. It goes without saying that, for one reason or other, many well known and first-class apples are omitted—several possibly for no more reason than that lack of space precludes the mention of more.

Dessert Varieties.

For eating in August, Lady Sudeley and Beauty of Bath are both good, if eaten from

Digitized by Google

the tree, though to keep them for more than a few days after ripening is to spoil them. Then, ripening in September is St. Everard, which, to my mind, is second only to a really good Cox's in point of flavour; it is not a very vigorous grower, but this is hardly a serious fault in the small garden. It certainly crops well enough when treated rightly. James Grieve follows, being eatable in October, and so regular in cropping and fine in flavour and appearance is this that the planter cannot afford to pass it by. Ellison's Orange is another fine October apple, the suggestion of aniseed flavouring appealing to many. Then we have Egremont Russet, the best and prettiest of all russets and a really fine garden apple, in season in October and November. In the north, some like Rosemary Russet better. For dessert in December we have Christmas Pearmain, of neat habit and a most regular cropper, providing nice-looking apples of good flavour. Laxton's Superb, next on the list, is an outstandingly good late variety; a most reliable cropper, the attractive apples are good to eat at any time between Christmas and early March. Following this there is Duke of Devonshire, a golden russety apple, at its best in March; and May Queen, a remarkably free cropper in season from January till May or later.

Culinary Varieties.

Coming to the culinary varieties, a good choice to provide apples for the earliest tart is Early Victoria (Emneth Early). This is followed by Lord Grosvenor (for northern gardens) and Lord Suffield (for southern gardens in which canker is not rife) for August and September dishes. Next comes Stirling Castle (September-October), of compact habit and a first-rate cooker and extremely fertile—so fertile, in fact, that if the trees are grown on a *very* dwarfing stock they will probably "crop themselves to death" in a very few years. Rev. W. Wilks follows, for use in October and November, and this is another extremely fertile sort that should be grown on a fairly vigorous stock; the Broadleaf English Paradise where bushes and trained trees are concerned. Next comes Golden Noble, which in its season—October to December—is the finest cooker of all. The popular Lane's Prince Albert, of rather "weeping" habit, but indispensable on account of its free cropping and fine big fruit, which keeps well into March, follows; and we cannot omit Newton Wonder, which keeps in good condition until May and which at any time in the New Year is not to be despised for dessert. The new apple, John Waterer, raised by Messrs. Waterer's and illustrated on the front cover this week, is a first-rate variety which keeps well into May. It is a heavy cropper, and the fruits are of large size and excellent flavour. It can be well recommended for planting in the small garden as a new variety of merit. Last of all comes Encore, a fruit much after the type of "Lane's," but keeping till June.

One other point the planter must bear in mind is that many varieties of apples will set little or no fruit, however profuse the blossom, unless the flowers are cross-pollinated. This means that it is most unwise to grow a solitary apple tree in the garden, or several trees of one variety only. Far better to plant two or three or more varieties, so that the pollen of one, carried by bees and insects, will cross-pollinate the flowers of the other.

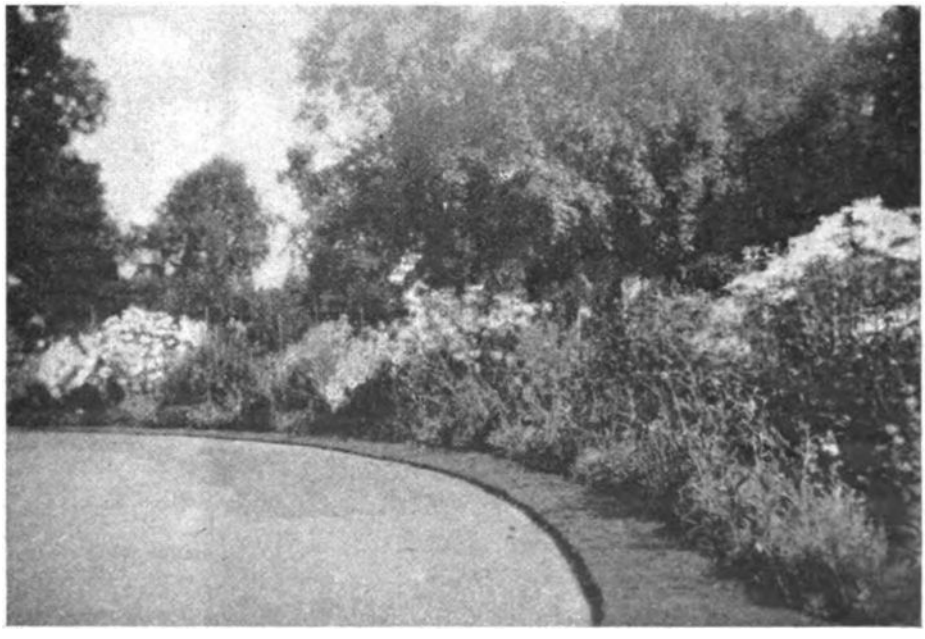
A CURVED HERBACEOUS BORDER

How to Arrange and Stock It.

A CURVED border is an agreeable variation from the perfectly straight ones generally seen in the back garden of the average small suburban house, always provided that there is enough space to permit a fairly bold and generous sweep. Supposing the garden to be about 130ft. long and 35ft. or 40ft. wide, the border may start at the house end of the garden with a breadth of 3ft. or 4ft., widening out gradually until it reaches 10ft. or 12ft. half-way down the garden and decreasing from that point until it ends with a group of flowering shrubs at the angle of the boundary walls or fences. Along the back of the border should be climbers on poles some 6ft. or 7ft. apart, four kinds of roses (two late and two early flowering, alternating with the same number of varieties of clematis, the sequence being repeated down the whole length of the border. Albéric Barbier, Goldfinch, Lady Godiva and American Pillar are suitable roses for the purpose, but there are many others, old and new, equally good; while as to the clematis, purple Jackmanni, Lady Caroline Neville, Nellie Moser and Princess of Wales are all well known and beautiful kinds.

Between and in front of the climber-wreathed poles will come the tall perennials, of which the delphiniums are the most important. Groups of these in light and dark shades of blue should be planted at intervals along the whole stretch of the border (their crowns, by the way, must be covered with ashes mixed with a little slum or the slugs will have them), and although a few of the newer varieties are still too expensive to suit light purses, yet many of the older sorts and unnamed seedlings can be obtained from nurserymen who specialise in delphiniums at a reasonable figure, and a very large percentage will turn out well. Between the delphiniums are planted other tall-growing perennials, such as Astilbe King Alfred and A. Davidii, Galega officinale, Bocconia cordata, Lavatera Olbia, Heliopsis B. Ladhams, Helenium Riverton Beauty, Anchusa italica, Thalictrum glaucum, Echinops humilis Taplow Blue (the tallest of its kind), the pretty pinky lavender Physostegia speciosa, Liatris graminifolia and Centaurea macrocephala with its golden thistle-like flowers. All these are summer blooming, and to ensure an autumn display these must be interspersed with asters of the Novæ-Angliæ and Novi-Belgii sections, Boltonia asteroides, Rudbeckia laciniata (single and double) and Solidago Golden Wings. Senecio tanguticus is another showy September-flowering plant, but is, perhaps, better fitted for the wild garden than the border by reason of its roaming habits. It does well in shade.

For the main part of the border, plants from 2½ft. to 4ft. will be wanted, and of these there are many from which to choose. Phloxes should be a special feature, and if massed in front of the delphiniums they will mercifully conceal the ugly, moribund stems of the latter. They may be of all possible colours, but care must be taken not to put the orange-reds, salmon-pinks and crimsons next each other, they should be separated by whites and soft lilacs. Among other desirable mid-border plants are Oriental poppies, especially P. bracteata Crimson King, which does not tumble down as tiresomely as most of its kind. The salmon-pink varieties are also good, but the white ones are apt to be flimsy of petal and not very pure in colour. Then there are the lupin hybrids (L. arboreus × L. polyphyllus), sidalceas white and rose, Chrysanthemum maximum (a dwarf strain), Erigeron speciosus, Liatris graminifolia, Pentstemon Newbury Gem, Achillea Ptarmica Perry's White, the golden-starred asphodeline (not often seen, but very charming), Salvia virgata, Campanulas lactiflora, persicifolia (especially Telham Beauty), latifolia and latiloba, Lychnis chalcedonicum, Agrostemma coronaria,



A CURVED BORDER WHICH HAS BEEN CAREFULLY PLANTED WITH BOLD GROUPS HAS A WELL FURNISHED APPEARANCE.

Digitized by Google

Catananche cœrulea (Cupid's Dart) and Veronica spicata, white and purple-blue. For a little nearer the front of the border there are such good things as that pretty cousin of the campanulas, Platycodon Mariesii, the two blue linums, L. narbonense and L. perenne, Malva moschata, Incarvillea Delavayi, Œnothera speciosa and Œ. fruticosa Fraseri, Geums Mrs. Bradshaw and Heldreichii, Potentillas Miss Willmott and Gibson's Scarlet, long-spurred aquilegias, Aster Amellus King George and A. A. Beauty of Ronsdorf, Aster acris and Rudbeckia speciosa, the black-eyed Susan of cottage gardens. These last four will make a brave show in September and October.

The planting of all these perennials must, of course, follow the curve of the border, but there should be no regular lines, the groups of plants of different heights must merge—perhaps "dove-tail" would be the better word—one into the other. The deepest part of the curve should be emphasised by bringing the taller plants well forward and for the same reason the colouring should be strongest at this point, shading gradually hence to the narrow parts of the border. Throughout the whole border there should be planted clumps of gypsophila—these, if placed close to the Oriental poppies, will hide the unsightliness of their after-flowering state—eryngiums (especially the silvery E. giganteum), small bushes of santolina, Artemisia Stelleriana and Salvia argentea, the soft greys of which will help to bring the diversity of gay colours into harmony. Liliums, for the most part, are rather expensive but there must be some groups of Lilium candidum. Galtonia candicans is an inexpensive bulb, costing only 3s. per dozen, and its tall spikes of white flowers are very striking in late summer, while the camassias, white and lavender, and the dainty anthericums, A. Liliago and A. Liliastrum, should find places near the front of the border. This, if slightly raised, may be edged with rockery stones, over which trailing and creeping plants of many kinds—alpine phloxes, aubrietias, helianthemums, campanulas, etc.—can be grown, but a "one-flower" edging seems to accord better with a curved border, and for this nothing is better than Nepeta Mussini, which remains in flower the whole summer, while its soft lavender-purple accords with all colours except scarlet. If a space is left at the back of the cat-mint, it can be planted with tulips and wallflowers for spring effect, followed by pale pink antirrhinums for summer blooming.

With the exception of a few such rampant growers as the Michaelmas daisies and rudbeckias, they should be planted not less than three in a group if a good effect is wanted quickly, but in most cases a single plant will produce an equal result—in time!

R. E. HEAD.

A DESIGN FOR YOUR GARDEN

A Suggested Garden Scheme for an Average-sized Plot.

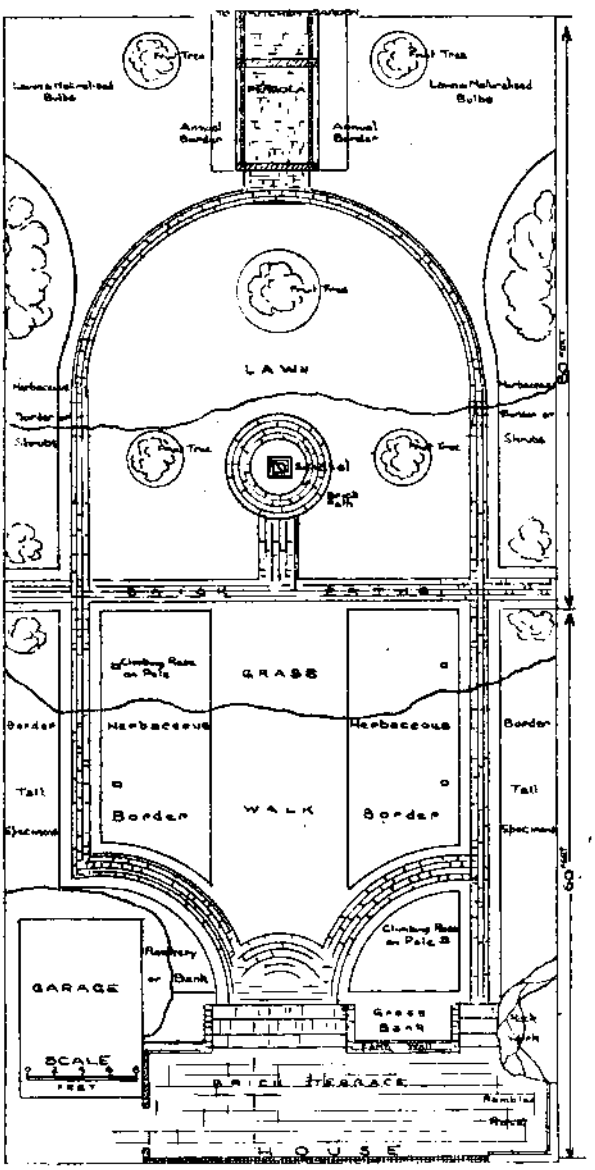
THOSE who are blessed with an intriguing piece of ground with perfect rural surroundings, a good view or other natural aids to the ideal garden, can allow their imagination full scope. Most of us, however, have to be content with the conventional oblong plot with a limited frontage of from 30ft. to 50ft. and a depth varying from 100ft. to 300ft.

In such a case the problem of laying out the ground to give the garden that added touch of individuality, which is one of its greatest assets, becomes more difficult. An unbroken sequence of beds or a long lawn accentuates its narrowness, while too much artificial obstruction is calculated to make the garden appear unduly small and pokey.

The accompanying sketch is a suggestion for overcoming some of the limitations of the orthodox plot, and, while it is designed for dimensions over all of about 200ft. by 40ft., reduction or enlargement to suit individual needs is not likely to interfere with the general idea. The kitchen garden portion of approximately 60ft. by 40ft. is omitted from the sketch (which is also foreshortened).

The basis of the scheme is the subdivision of the plot into three more or less equal parts, grass walk and flower beds, lawn and kitchen garden. Each section has its own special features. It may be said at the outset, by way of criticism, that the garage is in the way. It is a fact, however, that garages usually are in the way, particularly in the case of small houses. They can be satisfactorily camouflaged by suitable climbers and the construction of a rockery or neat grass bank to hide the unsightly foundations as shown in the diagram.

It will be noted that the view from the house or brick terrace is down a grass walk, reached by brick or stone steps, flanked by wide flower beds, on the outside edge of which are grass-bordered paths and narrower flower beds at the side. Careful arrangement of the planting will give a pleasing framework or banking of flowers to the view which is pivoted on a central sundial or bird-bath. The background is made up of a lawn with small beds and fruit trees. With the lawn in the situation shown a widening effect takes away any suggestion of narrowness to the plot. The smaller lawns to each side of the pergola are suitable backwaters for naturalising bulbs. A mass of narcissi and crocuses planted in the grass will make a conspicuous show in full view of the house.



A SIMPLE PLAN FOR A RECTANGULAR PLOT.

The pergola acts as the apex of the two side paths and forms a thoroughfare to the kitchen garden beyond. Assisted by grass banks to each side or a framework of loganberries it also acts as an effective screen from the possibly less beautiful inhabitants of the kitchen garden.

A scheme such as the above is well within the scope of the amateur gardener, as there are no intricate architectural features, and all sorts of variations and additional details can be included. If the aspect is southerly, the earth wall and rockeries near the house make ideal situations for those rampant rock cresses, stonecrops, saxifrages which seem to thrive in the dry places, while there is ample space for all those tall perennials which form such effective backgrounds to the general herbaceous borders. The placing of the flower beds enables a constant show of blooms to be obtained where they can be seen to advantage.

The road to the kitchen garden will indicate the intention to have a central path. I have found such a path extremely useful and space saving, particularly with another path set off at right angles so that the plot is divided into four. The amount of border thus created gives plenty of room for a full herb garden and each section can be allocated to a special purpose, such as bush fruits, strawberries, flowers for cutting and general vegetables on a small scale. One section can be reserved for propagation purposes and for that necessary evil, the rubbish heap and incinerator.

If the paths are made of brick or stone, it will be found that work in such a garden is not that mudlarking job which it can be under certain conditions, and every part is accessible in all weathers without the ruination of lawns.

Further possibilities of the scheme depend on actual conditions. Many small houses of post-war construction have low close fences or even wire or expanded metal and post boundaries. The question of wind-breaking and additional screening will arise. As will be seen, this can be done without undue reduction of the flower-bed area.

Indeed, if the immediate surroundings are pleasant, many gardeners welcome the open fences, for there is no

Digitized by Google

doubt that the plants are generally much hardier and free blooming and, in addition, surroundings can add to and enhance the general effect of a well thought out scheme of garden planning. In such a case the partial screen afforded by hollyhocks, delphiniums, Michaelmas daisies and other tall specimens in season will be found sufficient if planted in association with more permanent climbing roses, loganberries, etc., to give that privacy which makes a garden the place of rest and refreshment it is intended to be. L. G. B.

SOME OF THE BEST BEDDING ROSES

The most attractive varieties that have proved their worth for planting in the small garden. The list is sufficiently large to satisfy every taste.

MODERN roses must fulfil a dual purpose. There was a time when they were grown almost solely for exhibition; to-day they are required to create a display in beds and borders in the garden and to adorn the home for decorative work. And of all the flowers or plants known to gardens, with the possible exception of the sweet pea, none is better fitted to the demands required of it in regard to floral continuity than the modern rose. If we judge it from this particular aspect it is without a rival. What other plant, it may be asked, can give the garden or the home a display of flowers over so long a period as the rose? What other plant can have its flowers cut so consistently and will recover and bloom again so rapidly? There is none. The rose is supreme among hardy perennial plants.

The hybrid perpetuals held pride of place in gardens for a long period, but with the advent of the hybrid tea they gradually declined in popularity. When the hybrid tea was still further improved by the infusion of Persian blood, the doom of the, so-called, hybrid perpetual was sealed. To-day varieties in this section, with one or two notable exceptions, are practically neglected. The term hybrid perpetual was really a misnomer, and that name applies far more accurately to our modern hybrid tea and allied varieties. It is true, of course, that some hybrid perpetuals are very prolific in regard to flowering. Hugh Dickson, for example, will flower almost as freely as any hybrid tea, but one can hardly call this rose a hybrid perpetual. If we take Charles Lefebvre, Ulrich Brunner and Mrs. John Laing as typical examples of hybrid perpetuals, we cannot classify Hugh Dickson in the same category. In reality it should never have been placed in the hybrid perpetual section.

Hybrid perpetuals are still in favour with a few lovers of roses. There are some exquisite sorts still in commerce and they appeal to those who love a flower of good formation and an abundance of petal coupled with fragrance. The objection to these roses on the part of most people lies in their want of freedom, but for the benefit of those who wish to grow them the names of a few of the best are given herewith. Hugh Dickson, already mentioned, is known to most. Its rich crimson colour, its well formed flower, its fragrance, its freedom, and its hardiness and vigour have caused it to remain a worthy favourite for many years. Frau Karl Druschki is, perhaps, the next most popular favourite in the list of hybrid perpetuals. Like Hugh Dickson it has a large infusion of tea blood in its ancestry—it is a descendant of the illustrious Caroline Testout—and it is still the greatest of white garden roses. It is, unfortunately, scentless. We have still to get the ideal white hybrid tea rose, but there are one or two good things on the horizon and they will make their *début* next season. Hugh Dickson and Frau Karl Druschki are strong growers and must be planted in a position to suit their stature. If associated with hybrid teas they would be planted in the back row or in the centre of a bed.

Next in order of popularity in this section comes Mrs. John Laing. I am afraid, however, that its day is over. The new hybrid tea Dame Edith Helen is vastly superior. I have given the three most popular hybrid perpetuals to-day, and in order to make the number up to one dozen, I give the names of nine more of what I consider the best of this old race. They are General Jacqueminot, Duke of Edinburgh, Captain Hayward, Alfred Colomb, Charles Lefebvre, Ulrich Brunner, A. K. Williams, Suzanne Marie Rodocanachi and Duke of Wellington. This small selection is quite sufficient. If a dozen hybrid teas are chosen and planted in competition with any hybrid perpetual I am sure that the scrapping of the latter will be a certainty. The hybrid teas have been so much improved in so far as their utility and value are concerned, from the decorative and bedding aspect, that we do not now require the older sorts. The passing of the hybrid perpetuals was inevitable. I will grant that there are a lot of rubbishy hybrid teas, but, on the other hand, there are some remarkably fine ones.

The following list of hybrid teas and pernet roses may be relied upon to give satisfaction under average garden conditions. The sorts here recommended have all received a thorough trial. They are:—Angele Pernet, vivid orange yellow shaded reddish apricot; Betty Uprichard, salmon pink and carmine; Christine, golden yellow; Captain F. S. Harvey Cant, salmon pink veined with yellow; Colonel Oswald Fitzgerald, deep crimson flushed with deeper shades; Clarice Goodacre, ivory white; Charles E. Shea, clear pink; Caroline Testout, satin rose; Donald Macdonald, orange carmine; Dorothy Page Roberts, coppery pink suffused apricot; Etoile de Hollande, deep velvety red; Ethel Somerset, shrimp pink edged with a deeper shade; Emma Wright, orange; Gwynne Carr, shell pink shaded lilac; General MacArthur, bright crimson; Hortulanus Budde, vivid red with orange centre; Hawlmark Crimson, scarlet crimson; Isobel, a lovely single; J. C. Mensing, bright rose pink, and the best of the deeper coloured Ophelias yet raised; K. of K., a semi-double dazzling scarlet; Lamia, reddish orange; Los Angeles, coral pink shaded with gold and copper; Lieutenant Chaure, virtually a dwarf Hugh Dickson; Lady Elphinstone, apricot flushed with yellow; Lady Pirrie, coppery salmon; Lady Roundway, golden orange flushed copper; Lady Inchiquin, orange cerise; Mme. Jules Bouche, creamy white; Mme. Butterfly, pink flushed apricot and gold; Mme. Abel Chatenay, rose flushed carmine; Mme. Edouard Herriot, coral red; Mme. Melanie Soupert, saffron yellow toned pink; Mrs. Henry Bowles, rosy pink and salmon; Mrs. Oakley Fisher, a free flowering single; Mrs. Fred Howard, best described as an improved Mme. Ravary; Mrs. William Fife, a lovely shade of pale pink; Mrs. Wemyss Quin, a robust and reliable yellow; Miss C. E. Van Rossem, a semi-double deep velvety red of fine formation; Modesty, cream flushed with rose; Mabel Morse, golden yellow; Marcia Stanhope, white and fragrant; Red Letter Day, a semi-double crimson too free to overlook; Souvenir de Mme. Boullet, on the whole finer than Lady Hillingdon; Scarlet Glory, vermilion scarlet; Souvenir de Georges Pernet, orient red, distinct and good; Shot Silk, cherry cerise overlaid salmon orange, very sweet; The Queen Alexandra, included for its novelty; Una Wallace, cherry rose; William F. Dreer, silvery pink flushed yellow; and Westfield Star, a sulphur yellow Ophelia.

A DECORATIVE BED OF ROSE CAROLINE TESTOUT, OF A SILVERY SALMON PINK.
This variety, although one of the older sorts, is one that should not be omitted from any rose collection.

The above list contains fifty-five names, and a selection can be made from it with every confidence. One or two sorts will be noted which are somewhat new, but they have proved to be garden roses of the greatest merit. It may be that some readers will miss roses which they may fancy, but if they will send the names of any such rose the writer will be pleased to state his reason for its omission from this selection. An endeavour has been made to compile a list of the very best sorts for certain results in practically every garden. The past season has been a severe trial for roses, and every sort in the above list has given a good account of itself. The next article will deal with polyanthas, Chinas and musks, climbing roses will be reviewed in due course. GEO. M. TAYLOR.

THE BUSY MAN'S PAGE

How to Obtain Early Rhubarb.

THERE are several methods open to those who desire to have rhubarb for early pulling: (1) by lifting stools and bringing them into the heat of a greenhouse; (2) by placing stools in a dark shed or cellar; or (3) forcing in the open, by covering the crowns with straw and placing tubs over them. In the case of stools taken from the ground it is essential that after lifting they should be left on the surface two or three weeks in order to check them and give them rest. If the weather is frosty at the time, it will injure them very little, and when brought into heat will speedily make growth. It is the failure to appreciate the importance of the roots having a rest that causes the beginner in forcing stools to obtain poor results. Under the greenhouse stage, so long as light can be eliminated, will be found as good a place as any, and soil, or leaves and manure, should be packed round them and the crowns given copious supplies of water and liquid manure.

Next to a greenhouse, a frostproof shed or cellar is best. Here again, litter or leaves should be used to draw around the stools and thus generate a little warmth.

In the garden one can, without going to the trouble of lifting, have early pullings by making use of manure, leaves, and strawy litter. Sometimes in the autumn, manure is got in for use the following spring. It may be placed to good advantage by covering the stools with tubs and drawing as much manure and straw around them as is possible. It is mainly a question as to how much heat and moisture one may give as to when the first sticks can be pulled. Only strong crowns should be used for lifting, and those which have been forced the previous season left out of account.

PREPARING RHUBARB FOR FORCING.

The lifted stool is exposed for two or three weeks before taking into the greenhouse; the stool which is to be forced in the open is covered with straw and a barrel along with strawy manure.

Planting Out Biennials.

BIENNIALS such as antirrhinums, wallflowers, campanulas, anchusas, hedysarum, stocks and aquilegias that were reared outdoors will have attained a fair size and be in a suitable condition to plant out in their flowering positions. A good rich loam is desirable for them all, but the wallflowers are very partial to lime, and it ought to be added to the beds or borders before planting. Give plenty of room between the plants to allow air and light to get to them and to prevent stunting of the growths. Each plant should be lifted from its rooting quarters with a good ball of root and soil attached, each mass of the latter being given a gentle squeeze to make it compact. Planting should be carried out with a trowel, making the hole sufficiently large to take the ball of roots and soil, and the plants should be pressed in firmly, particularly wallflowers and antirrhinums.

How to Make New Flower Beds.

Treatment of the Soil.

EVERY year new flower beds are made in our gardens; some in old gardens and others in newly formed ones. The forms that are most satisfactory are those round, square and oval-shaped. Beds having narrow points—star-shaped—are the most unsatisfactory, because they cannot be filled with plants that will be effective in any way. Having decided on the form of the bed, the next point to consider is its size. If the garden is small, fewer and smaller beds would be more useful and interesting than large ones, which would, probably, occupy nearly the whole of the lawn. A good lawn, well kept, sets off the flower borders to the best advantage. The soil treatment should be carefully considered. When the new bed is being made all old, useless soil, roots, stones and all foreign matter should be removed to a depth of at least 2ft. and the space filled up with really good loam. There is no better time for high-class treatment of soils than when the border is clear of plants.

Frequently, cultivators are too hasty in dealing with their new flower beds, filling them with the first available soil, and then wonder why the plants fail to thrive in their new quarters. A really sandy soil should have some of a more adhesive character mixed with it; a clayey soil should have some of a light character added to it or in place of a portion removed.

Increasing Violas and Pansies.

DIVISION of roots is a very good way of increasing the stock of pansies and violas. This year, when there has been such an abundance of rain that the plants have quite recovered from their flowering time, the old specimens are growing very strongly indeed. Start by cutting the old growths back rather severely so as to encourage the development of the young shoots towards the centre of the plant. Follow on the cutting by sprinkling some light soil in the hearts of the plants to encourage the formation of new roots on the young stems. About a month later the division of the plants may take place, and it will be found that they winter much better than where the method of propagation has been by means of cuttings. Unless the locality is a mild one it is usually better to keep rooted cuttings in a cold frame, but plants divided in the manner described may be set right out into their permanent quarters at 9ins. apart.

Mossy Lawns.

FIRST seek the cause, then think of a cure. A really bad lawn may require to be drained when the moss is due to too abundant soil moisture, but this must be looked upon as a last resort, because it spoils the lawn for years. Less drastic but almost equally effective is the plan of lifting the turf, spreading a thick layer of garden ashes and relaying the turf on top at once. Mossy lawns, however, are not always due to dampness; starvation is a frequent cause. In such a case feeding must be resorted to. At this time a mulch of sand or, better still, sifted soil, leaf-mould or manure may be applied, a thin mulch which the rain washes down round the grass. In January or February bone meal may be applied at 3 oz. per square yard, or about this time slag at a ½lb. per square yard. Lime at ½lb. per square yard is also a good moss destroyer, particularly when followed in spring by light dressings of sulphate of ammonia and sulphate of iron or lawn sand. Sulphate of iron, 2 ozs. per gallon of water, also kills out moss, but before application tear out much of the moss with a garden rake. When moss appears on a light soil give the lawn a good dressing of kainit, 3 oz. per square yard, or scatter as much fine ash as possible over it, such ash being saved from bonfires of garden rubbish. Patches of moss should first be torn out with the garden rake, then dusted with lime; later a thin mulch of fine sifted manure can be laid on top and next year some bone meal applied.

Care of Tools.

IT undoubtedly pays to keep all garden tools clean during autumn digging. Whenever the work is finished, scrape the earth off each implement, then rub it with a coarse piece of sacking kept for the purpose. No water should be used, the implement being rubbed until free of all dirt and left like that. When, however, it may require to stand for two or three months, as often happens in small establishments, rub it the next day, when dry, with an oily rag. Tools should not stand outside longer than a day, bacause alternate rain and dry weather, heavy moisture and sun, frost and thaw, play sad havoc with the handles and either rot them or destroy their fine grip. Barrows, too, deteriorate more rapidly when left exposed than when in use. Garden shears, lawn mowers, scythes and other things which only come into use during summer may now be oiled or vaselined and hung up in a dry shed.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Autumn Cultivation.

DIGGING, taken in moderation, is the healthiest form of exercise. There are many advantages to be derived from digging during the next few weeks, instead of leaving the soil unturned until spring. Frost acts upon the particles of clay, reducing it to a powder. For some reason, autumn digging helps to keep the soil moist during the following season. One authority estimates that from two to three per cent. more water is retained in dry weather by autumn dug land above that turned over in spring. Except during very cold spells, nitrates are formed and other chemicals released and made available as plant food during the winter months, but this can only take place in a soil which is aerated.

Soil Pests.

WHEN plants are attacked by soil pests, it is usually not possible to do much during the growing season beyond setting a few traps and giving the plants a stimulant to help them to resist attacks. Now that the growing season is over, we ought to tackle those pests which can only be killed while the ground is vacant. An application of kainit at the rate of ½lb. to each square yard is one of the best ways of treating soil at this season. This kills such pests as slugs, and, in addition, acts as a fertiliser. Where a strong soil fumigant is desired, to kill wireworms, etc., mix a pound of crude naphthalene with 14lb. of lime, and apply at the rate of about a pound per square yard.

Pond Construction.

NOW is the time to undertake garden alterations that involve excavation work. Soil that can lie in the rough until spring receives the benefit of frost action. If it is intended to construct a lily pool, the work should be commenced without delay. It is surprising how long the work takes, and the few hours spent in excavations from time to time seem to make little headway towards the completion of the work. Then there is the cement work to be prepared, all of which takes a fair amount of time. Rushed work is never satisfactory in the garden, and to take time by the forelock with garden alterations is a good motto for the week-end gardener. Even where the heavier excavation work is done by contractors, wet weather, frost and other difficulties often delay the construction of garden features.

A Charming Grass Walk.

THE grass walk shown in the accompanying illustration forms a very pleasant vista beneath the pergola. The use of grass as a path has the disadvantage that in very wet weather it is not suitable for heavy traffic. But in the less frequented part of the garden, the grass path, provided it is adequately drained, makes a charming walk.

Carnation Culture.

Now is the Time to Transplant Layers.

NO plant is better fitted than the carnation to withstand the conditions of the town. It is a bonny fighter. It has been provided with a coat of wax to protect it from the breezes from the sea, and this shield makes it more or less immune to the poisonous airs of the town. In dry seasons it can thrive when other plants become limp and flaccid.

THIS IS THE TIME WHEN ALL RAMBLER ROSES SHOULD BE THINNED AND PRUNED, REMOVING ALL DEAD WOOD AND ALLOWING THIS SEASON'S GROWTH TO RIPEN AND MATURE.

The cultivation of border carnations is extremely simple. The soil must be well drained, and the site a sunny one. An ideal soil for carnations is a chalk or limy soil; but with artificial aid any ordinary garden soil will produce good results. If the soil has already been well prepared the plants can be put in now. But if the soil is badly drained or deficient in lime, the plants may not live through the winter. If it is decided to wait until spring, dig the soil roughly now, leaving the surface very loose so that frost and rain can penetrate. Five ounces of lime per square yard is not too much to add when digging the soil of the town garden.

How to Plant.—Do not plant too deeply, but make the soil sufficiently firm to hold the plants in the ground. From 9ins. to 15ins. space should be allowed between each plant. Winter frosts have a tendency to loosen the plants in the soil, and after a spell of severe weather the surface soil should be again firmed round the young plants.

There is no necessity to protect the plants by litter or leaves. Wood ashes, if available, can be used as a dressing between the plants, and these help to keep away insect pests.

A selection of a few of the best carnations for border culture is as follows:

Border Yellow	.. Of good border habit.
Grenadier	.. A fine scarlet self.
White Fox	.. Large, pure white self.
The King ..	.. Dense maroon self.
Gordon Douglas	.. Wine crimson self.
Effie Deans	.. Apricot self.
Rosetta ..	.. Rose self.
The Grey Douglas	Lavender grey.
Cleopatra ..	.. Rose madder, barred scarlet.
Linkman ..	.. Yellow, with scarlet markings.

A SMALL FORMAL POOL WITH WELL FURNISHED SURROUNDINGS.

NOTES ON THE FLOWER GARDEN

Treatment of Early-Flowering Clematises.

THERE is apt to be much confusion and subsequent heartburning concerning the treatment of clematises, and those types that are most likely to be treated wrongly are the spring and early summer classes, which both in habit and constitution are entirely different from the later-flowering sorts. These early-flowering clematises are those of the Calycinæ group, which produce flowers in the winter of a creamy white; the Anemonifloræ type, such as C. montana; the Azuræ type, which is illustrated; and the Floridæ group, another large-flowered clematis. To these must be added the Lanuginosa class of clematis which, although blooming from July to October, nevertheless require the same treatment as the spring-blooming kinds.

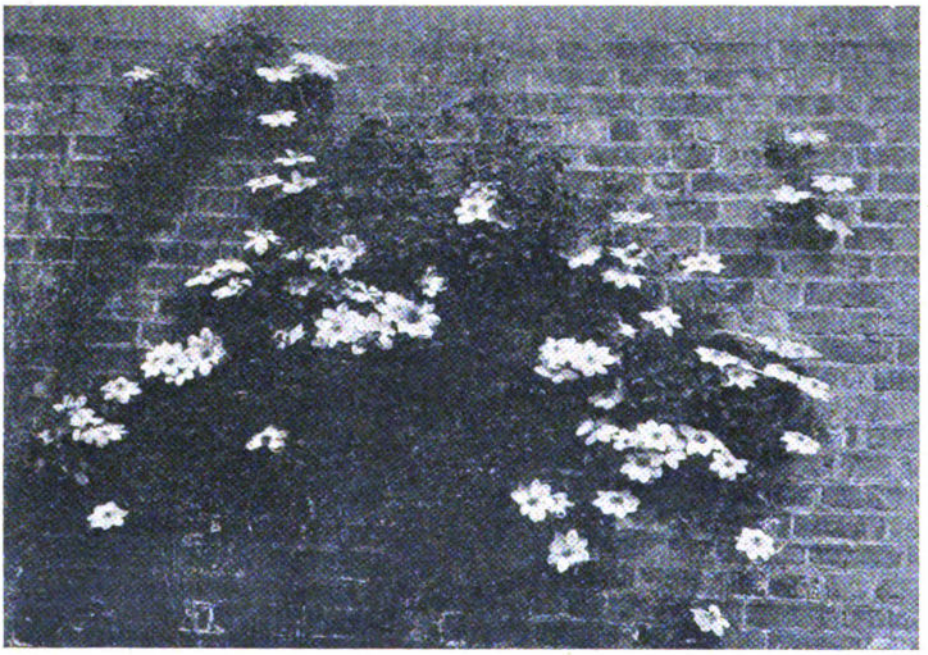
It should be noted that *all these clematises flower on the old or ripened wood*, so that should any of this be cut away in pruning it represents a corresponding loss in blossoms. This is an important point to emphasise, and whatever pruning is given, should be accomplished during the month of February, and the pruning, moreover, should not extend beyond the removal of exhausted wood, overcrowded or straggling branches, and in cutting out all weak shoots. All cutting that is done in addition to this is not pruning, but mutilation, to the great detriment of the plant it is practised upon.

As these clematises pass out of flower, next year's shoots are produced, on which will depend the crop of flowers the following May; and if these shoots are interfered with in the way of natural growth, they will not produce the desired wealth of blossom. Every inch of new wood should be carefully preserved, trained in and tied to supports. Next February all the unripened ends may be cut off, together with other useless wood.

Besides these things, it should be remembered that the vigour of climbing plants like clematises needs to be sustained by substantial manurial applications, especially during hot, dry weather; and as the clematis is invariably planted at the foot of a wall or fence or pergola, where it may get but little moisture at the roots, the best thing to do is to provide a substantial mulch over the roots as soon after flowering as possible, preferably of rotten manure or, failing this, a quantity of leaves or other moisture-retaining vegetable matter. This, with an occasional bucket of water, will be the means of aiding the growth of the plant and considerably adding to the size of the flowers.

Those who contemplate planting the early-flowering clematis should do so either now or in the spring. Remembering that all clematises like a somewhat shady position, the site should be selected accordingly. The right kind of soil is a rich loam of somewhat light texture, which contains an admixture of lime or chalk. This, however, is not always available naturally, but could be given immediately around the roots when planting.

As a rule, the early-flowering clematises are best given a site beside a brick wall that is not too greatly exposed to the sun, and in this respect they make admirable plants for training by the side of the entrance door of the home, where their early blossoms are very welcome and ornamental. —N. E.



CLEMATISES ARE AMONG OUR MOST DECORATIVE CLIMBERS FOR WALL DECORATION.
No garden is complete without at least one of the many beautiful hybrid varieties.

Dwarf Michaelmas Daisies.

FOR the small garden or in the front part of the herbaceous border the various forms of Aster Amellus are strongly recommended for an autumn display. They form rather dense clumps, and when in bloom vary from 1½ft. to 2½ft. high. Although they are more or less free growing, they are not so aggressive as many of the Novi-Belgii section, a fact to be borne in mind by the man with a narrow or small border. Some recommend that asters should be lifted annually, divided into small clumps and replanted. This is sound advice for such strong growers as Climax and its tribe, but for the Amellus group I doubt the wisdom of such remarks, hence this note. I have found several of the smaller-flowered kinds much better the second and third year after division, and this work is best carried out in the spring. It is a point on which readers' views would be welcome.

Among the large-flowered forms of A. Amellus is King George, now a most popular variety with its large striking rich violet flowers fully 3ins. across. The florets are broad and not too crowded, while a fully developed blossom is most beautiful. To make sure of upright sprays of bloom for cutting purposes it is advisable to afford the plants a few stakes or short pea sticks before the growths bend over. Another fine form is Rudolph Goethe, somewhat similar in colour to the preceding variety. Beauty of Ronsdorf is a beautiful lilac pink, the flowers being over 2ins. across, and another pretty rosy pink is Perry's Favourite, a plant that should be represented in all gardens. Coming to the older varieties with rather smaller flowers, but none the less beautiful, we find the later-flowering Ultramarine, a very bright blue and, moreover, the colour is intensified under artificial light. Then we have the handsome Framfieldii with its violet-blue flowers; Preziosa, rich blue; and Onward, a deep purple blue. There are a few other useful varieties, but the above are some of the best in the Amellus section, and are worthy of attention from the small grower.

Where the soil is of a heavy, retentive nature, lifting and planting should wait till next March or April, and even if the rooting medium is the reverse, spring planting is to be preferred. When this work is carried out in the autumn or winter, slugs and other pests are often troublesome, and in consequence many plants are lost.—T. W. B.

A Decorative Autumn Shrub.

BERBERIS THUNBERGII forms a compact, bushy plant from 3ft. to 6ft. high and even more in diameter. It is deciduous, and its real beauty is seen during the months of autumn. At this season the leaves turn a beautiful scarlet. An additional charm is its wealth of bright red berries, which are very useful for house decoration. Owing to its freedom of growth, it is a good subject for this kind of work, and, moreover, it appears to thrive in any poor stony soil. I believe most members of the berberis family fruit much more freely in a poor rooting medium than in a rich root-run. It is pre-eminently a shrub for the amateur's garden.—B.

A Good Plant for a Retaining Wall
Cotyledon simplicifolius.

THIS is quite a distinct species, admirably suited for walls or the rock garden, and, moreover, it is easily grown and quite hardy. It gained an award of merit from the Royal Horticultural Society in June, 1915, and since then it has gradually found favour with all lovers of hardy plants. The leaves are fleshy, forming small rosettes, and the plants possess stoloniferous root stocks, which are not too rampant even for the choicest rock garden. It produces graceful racemes of golden flowers from May till July, and when fully grown is about 6ins. in height.

A fairly sunny aspect should be chosen, and one where the slightly drooping spikes will be seen to the best advantage. The drier and raised positions of the rock garden would suit it best, and a gritty rooting mediun will meet its requirements in the way of soil. Small pieces of rock, stone chippings or old mortar rubble mixed with loam are recommended for this charming plant. It is perennial, and a patch on a retaining wall would be very effective.

This cotyledon can be raised from seeds, and also increased by runners or division during the autumn months.—W.

Four Chinese Rhododendrons Worth Growing.

AT Bowness-on-Windermere in 1919 we planted four Chinese rhododendrons. They were Rhs. calophytum, decorum, Houlstonii and sutchuenense. As, in flower and leaf and time of blooming, they are so striking and so different from the ordinary garden hybrid, a description may induce others to try them and other similar species, especially amateurs with small gardens.

First, as to planting. No special preparations whatever were made. The soil is the common Lake District stony, sticky "mud," from the blue stone and slaty rocks, now believed to be of volcanic origin and free from lime. The plants have been entirely open to the sun, without any special treatment of mulch of leaves till this year, but sheltered from the wind.

They are absolutely hardy as regards winter frost, but suffered in 1926 as to their new growth in the very severe May frosts, all except Rh. Houlstonii, which, making its growth in July, entirely escaped. Too much stress cannot be laid, I think, on the value of plants which grow at this season, and are otherwise able to stand a northern climate.

A short description, together with the illustrations of three of the plants will enable one to bring out the different features and the marked individuality of each. It is this individuality—not of flower only, but of leaf and growth—which gives to rhododendron species their special charm. We will take first the least satisfactory of the four—Rh. decorum. This has grown into a sturdy bush. It has dark green, stoutish leaves and forms flower buds regularly every year. Unfortunately seven years ago we did not know that there are several varieties of decorum. These flower from early May onwards; the later-flowering varieties are not adversely affected by alternating cold and warm spells—which is the usual story of our winters—and it is these later-flowering varieties which should be planted. The buds of our Windermere plant, open in early May, the flowers being of a very delicate pale pink, with seven petals to the flower, and have an exquisite spicy scent.

Rh. sutchuenense has made the biggest bush. It is a grand species. Its long, narrow leaves, which hang down vertically in cold weather, its huge terminal buds and pink trusses which open in March or April, are all very striking. This species has no scent.

As for Rh. Houlstonii, this flowered for the first time in 1926, probably helped by the hot summer of 1925, which helped to ripen the wood. This species has grown well and is a great acquisition to a northern garden. It flowers in early July, when other rhododendrons are over. The trusses resemble Rh. decorum; the flowers are a delicate pink colour, each flower being well shaped with seven petals beautifully fimbriated at their edge. Their greatest attraction is the strong and delicious spicy scent. One truss was enough to fill with scent a small room. The young foliage is also very beautiful—an emerald green colour, and below the new leaves hang the scarlet bracts. The growth, being made in July, cannot be damaged by frost.

Last of the four is Rh. calophytum. This is now, of course, fairly well known. It should be in every garden, large and small. The illustrations will give some idea of its exquisite flowers. These are bell-shaped, of the purest white, and inside of the uppermost petal is a deep, rosy blotch. A big, knobby, yellow-coloured stigma adds to the picture. This species is absolutely hardy, flowers when a small plant, and, like sutchuenense, in March or April.

These plants from the western provinces of China, have proved their worth at Windermere. May this short note induce many others to plant them and many other beautiful rhododendron species as well.—G. LISSANT COX.

THE DELICATE PINK AND FRAGRANT FLOWER TRUSSES OF RH. HOULSTONII.

RH. CALOPHYTUM SHOULD BE IN EVERY GARDEN.
It is handsome in flower and elegant in foliage.

RH. SUTCHUENENSE IS A FINE SPECIES FOR A NORTHERN GARDEN.

SWEET PEAS FOR THE GREENHOUSE

For those who wish early sweet peas, seeds of some of the more choice varieties should be sown now and the plants grown on in the greenhouse. Fine blooms will be obtained in the first days of early summer.

THE sweet pea is generally regarded —and rightly so—as an outdoor flower, nevertheless, very probably the finest specimen blooms ever produced have been grown under glass in cold houses. Many readers must have noticed the wonderful quality of the exhibits of sweet peas at Chelsea Show of recent years; these were all greenhouse grown, on the "single-stem" or "cordon" system. Greenhouse culture has many advantages, it also has its disadvantages. In the first place there is no more interesting way of growing sweet peas, although it exacts a little more care and skill on the part of the grower. It gives one earlier flowers, and the actual appearance of the blooms is different in a manner readily perceptible, but difficult to convey in words. Greenhouse blooms are much cleaner looking, and the daintiness of form which is one of the most attractive characteristics of the sweet pea is further enhanced. The plants are much more under the control of the grower than outdoors, and there is, for some obscure reason, a welcome absence of that mysterious disease, or alleged disease, "streak." Some varieties are seen at their very best under glass, others are not nearly so pleasing as when grown outdoors. Generally speaking, their shades are paler inside, perhaps richer toned in many cases, but not so clean cut and vivid.

Greenhouse treatment varies very little from outdoor culture, whether the plants are grown naturally or restricted to a few "leaders" only. A fairly lofty structure is best, and in any case it should not be lower than 5ft. at the eaves. Ground space will naturally be limited; indeed, in many cases it will be necessary to grow them in large pots. Undoubtedly best results follow when the sweet peas can be planted out in well prepared trenches in the soil of the greenhouse. The procedure in this case is quite simple. Take out trenches 18ins. to 2ft. wide, 18ins. to 2ft. deep, allowing 3ft. between the centres of each—that is, 3ft. from row to row. All that is needed is just enough room to walk easily between rows. When trenching, well mix in a liberal amount of decayed horse or farmyard manure to within 9ins. of the surface, if possible incorporating at the same time a good dressing of bone meal and burnt wood ashes throughout. A firm rooting medium is essential, so the soil should be well trodden down as the work proceeds. Should the greenhouse soil be poor or sour, it is advisable to remove at least the top 12ins. of the trenches and replace it with good, fresh soil from the garden. The remains of an old hot-bed or a well decayed garden refuse heap will come in very useful for this purpose. The earlier the work of trenching and manuring is completed the better.

If large pots have to be used, a good fibrous loam with a little wood ash and bone meal mixed in is effective, but do not add animal manure unless it is well decayed. If possible, stand, or partly plunge the pots in a richly prepared bed, enlarging the drainage holes in the pot bottoms to allow the roots to find their way through easily. Alternately, if the greenhouse has a tiled or concrete floor, the pots may be plunged in boxes containing enriched soil. Leave a space of 2ins. at the top of the pots for top-dressing later on.

Seeds should be sown now in pots in a cold frame and the seedlings grown along hardily and sturdily in the manner fully described in THE GARDEN of October 1st. Towards the end of January, bring in the plants in their pots and let them remain a few days in the greenhouse before transplanting. Water the trenches several days before planting out, taking care not to get the soil too stodgy and sodden. Then plant the seedlings firmly, 6ins. to 8ins. apart and do not water (except sparingly, if necessary) until they have recovered from the slight check of transplanting. Endeavour to maintain a fairly equable temperature at all stages of their growth and make no attempt to force them. Plenty of fresh air should be the rule. Short twigs will support the plants until rapid growth commences, then their permanent supports must be given. Wide mesh cord netting makes a fine support, sticks as a rule take up too much room. Do not feed the plants in their early stages, just water with pure soft water when they need it, frequently loosening the surface soil with a hoe to prevent "caking." When the plants commence flowering, apply a surface mulch of loose horse litter or spent hops round their base and assist them with periodical feedings of well diluted liquid manure and soot water. In the early summer, any tendency of the greenhouse to become too hot should be counteracted by syringing whitening over the glass and giving all the ventilation possible. If greenfly makes an appearance, spray the plants with a good insecticide, cleansing the foliage about twenty-four hours afterwards by spraying with pure water. Not often does mildew affect them, but this can be checked by spraying infected plants with a solution of liver of sulphur, ½oz. to the gallon of water.

As previously intimated, some varieties are more suitable for under glass culture than others. All those having a fair proportion of salmon or orange in their "make-up" are excellent, an especial favourite of mine being that vivid orange, Royal Sovereign. Here are a few other really first-class greenhouse sweet peas. Wizard and Colorado (orange), Gold Crest (salmon), What Joy and Matchless (cream), Ivory Picture (ivory), Venus, W. J. Unwin, Miss California and Magnet (shades of cream-pink)—Magnet is most delightful under glass—Mrs. Horace Wright, Hebe, Mrs. Chas. W. J. Unwin, Del Monte and Supreme (pink shades), Grenadier (scarlet-cerise), Charming, Centaur, Coralline and Peggy (cerises), Chieftain and Royal Mauve (mauve), Powerscourt, Mermaid, Gleneagles and Austin Frederick Improved (lavender shades), Dainty Maid and Elegance (blush), George Shawyer, Royal Pink and Crusader (orange-pink), Mammoth and May Unwin (orange-scarlet), Model and Avalanche (white).

C. H. A. S.

PROTECTING TENDER ROCK PLANTS in WINTER

Many amateurs who grow attractive rock and wall plants, such as the androsaces, will find some useful hints given in the following article on how to bring them successfully through the winter. In many districts great difficulty is experienced in keeping the plants. This writer has succeeded and his advice may prove useful to others.

AS a group, these valuable and exceedingly pretty alpines well repay a little extra and individual attention in autumn, with a view to their health and safety during the winter, which, in most parts of this country, is vastly different from that of their native habitat.

In the first place, there is no doubt that all the varieties benefit greatly by a suitable mulch, properly applied in early autumn. If this is done as soon as convenient, it will carry them through the winter and will be all the attention the roots will need until next season, and will go far towards good growth and freedom of bloom next spring and summer.

An ideal mulch may be formed by thoroughly mixing a quantity of well rubbed peat with about an equal amount of fairly light and very gritty soil; any good loam which is quite free from manure of any kind—the latter being deadly to androsaces—plus plenty of really coarse sand, will answer the purpose. The mixture should be sprinkled, not only on the ground surrounding the plants, but also among and over the rosettes themselves, and worked well in between them with the fingers. This method will be found to be much more satisfactory than watering-in the mulch, for, unless the water is very carefully applied, the tendency will be to wash the mixture away down the slope of the rockery, rather than in among the rosettes. Should the plants be situated in a dry wall—they do quite well there—some of the mixture may be stuffed in around the rosettes and between the stones, and a number of smaller stones wedged in wherever they can be got, to hold the mulch so that it does not so easily fall or wash out.

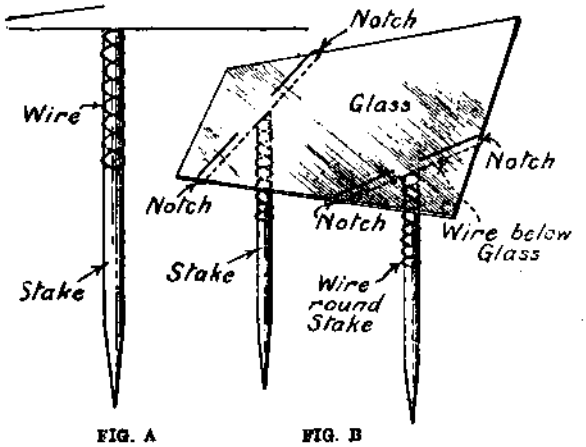

FIG. A FIG. B

The second duty is more difficult to undertake successfully. Many of them have, to a greater or lesser degree, woolly, downy foliage, and, in common with other such plants, an excess of overhead moisture is highly detrimental to them, if not actually deadly.

Some means, then, must be employed, in such a wet winter climate, to prevent undue moisture falling or resting on the foliage, particularly in damp neighbourhoods where the rainfall is excessive, when, in long, wet periods, there is little drying-off of moisture by evaporation.

Digitized by Google

The writer has found it generally advisable in such districts to cover his androsaces in October and to leave the covering on until March at least. Now, the bald instructions of the text-book, or "Garden Notes of the Week": "Cover androsaces with sheets of glass," would seem quite inadequate for any but these most accustomed to the process, for it is easier said than done—that is, satisfactorily! The position of the plants between the stones and in the more or less vertical fissures in which the androsaces seem to delight renders the actual covering anything but easy, and the fixing of the covers to withstand wind and snow and accidental disturbance is a matter demanding ingenuity and care.

Cloches, bell glasses, miniature frames and so forth, even if they could be fixed, will not do, for at no time, even in the severest and wettest weather, must the plants be without the free circulation of air and light to which they are accustomed when totally uncovered; neither must the covering be such as will prevent adequate supply of moisture to the roots. Moreover, some arrangement which allows of easy access to the plants without removing the covering is useful in case of emergency.

After many experiments, I have found a method, described below, which seems to be most efficacious and satisfactory from every point of view. Everything, except the actual fixing, may be done indoors on a wet day, some time before the covers are needed, and once constructed they will last two or three years, perhaps longer, according to the durability of the materials used.

A number of sheets of glass—the lighter the better—must be obtained, such as may have come from old windows or frame lights, and they must be well cleansed before use. If some are broken and irregular in shape, they will be none the worse, for they will be found convenient for fitting between rocks and in places where a regular sheet would not go. Next, a quantity of fairly strong but not too thick or clumsy stakes, of lengths varying from 1ft. to 2ft. 6ins., must be procured and sharpened. Natural stakes from shrubs or trees, such as are often used as chrysanthemum or gladiolus sticks, are much to be preferred to canes—firstly, because they are less conspicuous, and secondly, the wire which we shall use will grip or lick the support more tightly and will not slip. Some strong but fairly pliable galvanised wire is the only other thing needed. The pliability should be such that the wire may be easily bent and twisted with the pliers. A strand of this, say a yard in length, should be taken and, beginning about half-way down a stake, tie and secure one end. Then wind the wire clockwise and upwards round the stake, as tightly as it can be drawn, until the top is reached. Repeat the process with a similar strand, working this time "anti-clockwise," and finish so that the last wind of each strand nearly coincides with the tip of the stick. The two pieces of wire must then be twisted and tied at the top securely, so as to form, as it were, one length, lying across the top of the stake. The result will be, as may be seen in the rough sketch in Fig. A, the form of a T.

All that is necessary now is to take the glass and prepared supports and, by visiting each plant in turn, select a sheet of glass of sufficient size and suitable shape to fit the position as regards the surrounding rocks, in each case.

If the glass is in various sizes and forms, a little interchange will soon result in a satisfactory choice. Then revisit the plants in turn, and hold the chosen piece of glass temporarily in its position, and note approximately where two (generally sufficient) or more of the stakes may be safely and securely inserted in the ground without injury to roots. Remove the glass, drive in the supports with hammer or mallet, only sufficiently far to be firm, and to clear the surrounding stones comfortably; or, if there are none, to clear the group of rosettes by about a foot. Then place the glass flat on the top of the two or more "Ts" thus fixed, and notice where the wires cross the glass. At the edges of the glass at these points, a slight notch may then be easily made by a nip with the corner of a pair of sharp pincers or pliers. Having done this, re-lay the glass in position on the wires, make sure there is no rocking, and turn up the surplus ends of the two wires across the upper surface of the glass to form a kind of tight socket, and nip the bends as tightly as possible without cracking the glass. A reference to Fig. B in the sketch will show what is intended.

In some cases the natural slope of the rockery will be sufficient to ensure that water will run off the glass quickly and clear of the plant. If, however, this is not so, the lower side of the supports should be driven in deeper than the upper; in this way an adequate fall is assured and all chance of drip avoided. If the glass is heavy or large, there may be some slight swaying; but if well fixed it will be negligible, and the writer has found that this arrangement, if carefully carried out, is completely effectual and quite secure, even in high winds and heavy snow; and only very rough usage will result in displacement.

For those who do not care to go to the trouble of making these protective coverings a ready and effective substitute can be found in the Alpine Plant Protectors supplied by the Chase Continuous Cloche Co.

These covers, being open on all sides, admit all the light and air possible, access is readily gained to the plants, and, if ingeniously placed, the glass wards off all excess moisture. The method has also the advantage of being cheap and, if fixed with care, the arrangement is not unsightly or dangerous. Such a method may, of course, be adopted with subjects other than the androsaces, and which dislike too much overhead moisture. J. R. K.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints (which should not exceed 150 words in length) is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT

An Ideal Way of Storing Onions.

Onions will want considerably more drying this year owing to the wet season. A good way to store them is on trays made of small mesh, about 1in., wire netting. A piece of netting 3ft. to 4ft. will be wide enough. Thread a stick through each end and suspend them shelf-like in tiers about 8ins. or 10ins. above one another. These trays enable the air to pass between the layers of onions from the bottom as well as the top and prevents many of them going bad through dampness. This method of storing does not need much space and allows them to dry thoroughly.—A. J. F.

Double Arabis.

Arabis albida flore-plena for Spring Bedding.

This most useful plant is generally associated with rockeries, but is also most valuable for a groundwork in any scheme of spring bedding. A good display may be obtained in the following manner: At bedding-time, in early October, secure good, strong cuttings and prepare in the usual way, planting three or four in a bunch in the prepared flower-beds. These root readily and in spring will produce fine sprays of blooms resembling miniature stocks. This is a great saving of labour, thus obviating the necessity of preparing plants as is usual with such subjects as aubrietia, etc. Double arabis interspersed with Tulip Pink Beauty forms a pleasing and effective combination.—C. N.

To Keep Echeverias.

I find the following a very simple and efficient method of keeping these attractive and useful edging plants during the winter.

In a sheltered position of the garden, preferably against a fence, bank up the soil several inches above the surrounding soil. Plant the echeverias, as closely as possible, in this raised portion and then prop pieces of glass, a few inches above them, on bits of firewood driven into the soil around and between the plants. Smaller pieces of glass should be placed round the sides, but not to exclude too much air. Stones will keep the glass in position during windy weather. I prefer this method, as one can practically forget the plants all the winter, whereas cold frames require attention. I find my echeverias come into bloom weeks before it is safe to plant out and I very rarely lose any.—E. B.

Autumn Sowing of Sweet Peas.

The autumn sowing of sweet peas is a matter of vital importance to exhibitors and others who desire first-class blooms early, and it invariably results in the choicest flowers being ready in good time. Where cold frame culture is favoured, and it is generally advisable, the seeds are usually sown in pots or boxes. Being short of small pots, I have adopted the following method with good results: Procure some good loamy turves and lay them in the frame, cutting them to fit close together. They should then be cut into squares of about 3ins. and two seeds sown or planted in each square of turf. When planting out time comes in the spring the squares of turf can be taken out separately, thus doing away with the risk of damaging the roots through digging them up out of a solid bed or box.—H. A. H.

Economical Plant Supports.

When cutting down tall herbaceous perennials, such as solidago or Michaelmas daisies, do not throw away the faded flower-stems, for these, if dried, make useful plant supports for next year. Cut back the perennials fairly close to the ground and gather together all the stems. After stripping off the leaves and faded flowers, tie the stems in bundles and hang them up or place on a rack in the potting shed to dry. The leaves can be stripped off quickly and easily, by rubbing the stems downwards from the top to the bottom with a piece of cloth or sacking. When dried, these stems are woody and rigid, and they make inconspicuous and highly satisfactory supports for many kinds of plants, including border carnations and annuals.—T. B. T.

To Preserve Bamboo Canes.

When taking up the bamboo canes previous to storing them, procure a jam-jar half filled with creosote, into which dip each end of the cane. This not only preserves the cane, but all insect life is killed. A pint of creosote will do a hundred canes.—H. B.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

TRULY the climate in Scotland is a source of great perplexity to all horticulturists. So far, October has been a month of glorious summer weather that partly compensates for low temperatures and rain experienced in August and September. The display of roses at this late season has exceeded all expectations, and given satisfaction to amateur growers who take pleasure in sporting a buttonhole of their favourite variety. General McArthur, Earl Haig and W. C. Gaunt among the crimson classes, and Mrs. Henry Morse and Betty Uprichard in the pink shades have been outstanding, but Shot Silk has been the gem of the autumn.

It is a common practice when flowering is over to cut down the stems of early chrysanthemums and leave the roots undisturbed in the ground in the hope that they will survive the frosts of winter and bloom again in the following season. Occasionally these expectations are realised, but the risk is great and certainly not justified by the gardener who has a frame or cold greenhouse at his disposal and who aims at propagating new stocks by cuttings. The safer plan is to lift the plants and transfer them to a frame, where they may obtain the shelter that is necessary during spells of severe weather and throw up a plentiful supply of fresh green shoots for cuttings, which are usually struck in spring. While the absence of a frame is a handicap to the amateur in respect of preserving chrysanthemums, he will find a simple alternative that will insure him against total loss in boxing the roots in ordinary garden soil and storing them in a shed or outhouse, where they can be covered during periods of frost. He may only be able to treat a limited number in this way, but these will be sufficient to preserve his stocks, with the addition of any specimens that may survive the winter in the open. Chrysanthemums depreciate after their second year, and the finest blooms are obtained by raising new plants annually from cuttings.

The treatment of the loganberry is very similar to that of the raspberry, which is one of its parents. Cut off the old fruiting canes level with the ground, and when selecting the new shoots that are to be retained for the future furnishing of the plant, see that plenty of space is provided for the development of the lateral growths. Owing to its natural, vigorous habit the canes require to be properly trained and tied, otherwise they may form a tangled mass and encroach on the space occupied by other subjects. A wire fence or a wooden paling such as is used as a boundary to housing scheme gardens offers ideal conditions for the successful cultivation of that useful fruit. This is a good time of the year to put in new plants, while established specimens benefit by a dressing of stable manure at this season. If that material is difficult to obtain, substitute bone meal or kainit, 1lb. of which is sufficient for three bushes.

Sweet peas that were planted about the end of September or early October, and have been germinated in gentle heat, should be removed to a frame and grown on under cool conditions. Plenty of air is conditional to the production of sturdy, short plants, and except during hard frost the lights may be taken off altogether in daytime. In that case it may be necessary to cover the frame with wire netting of a close mesh so as to protect the seedlings from the attention of birds. The transference of the pots or boxes to the frame affords a suitable opportunity for checking the germination of the seeds. Where blanks occur a careful search should be made for the seeds by removing the covering of soil with the blade of a pocket knife. It may be that the seed has decayed, but frequently it will be found to be as hard and sound as when it was sown. In that event chip the skin and put the seed back in the soil, where a fair percentage of germination usually follows.

Though strong to start with, many wallflower plants present a disappointing appearance by the time spring comes round. A large percentage have only single stems, thin and drawn out, while the leaves on the lower parts are conspicuous by their absence. In that condition they are neither useful nor ornamental, for the bloom, if any, is sparse and irregular. To prevent such unfavourable results, the tops of the seedlings should be pinched in autumn, so as to promote the growth and formation of strong, bushy plants. When the seedlings are transplanted in their permanent position the opportunity should be taken to cut back the long tap root. This treatment promotes the formation of a root system composed of numerous thin fibrous shoots which also contributes to the production of healthy, vigorous growth, followed by a profusion of bloom.

Much may be done during the autumn and winter months to check the ravages of fungoid diseases and insect pests by cleansing fruit trees and bushes. Any caustic winter wash applied as a spray will destroy the dormant spores and invisible eggs that winter on the trees, and, as an additional precaution, the ground should be dressed with lime and kainit. The preparation of winter washes involves both time and trouble, which may be prevented by purchasing one of the reliable proprietary preparations obtainable from any seedsman, and applying it according to directions. Gooseberry and currant bushes, and all descriptions of fruit trees, benefit by an occasional spraying between the months of November and March. Old clothes and an old pair of gloves should be worn when spraying is done.

Fruit trees that have made too much wood at the expense of the crop may be restored to a condition of fruitfulness by root pruning. It is an operation, however, that should always be performed by a skilled person, because in the hands of an inexperienced operator the work associated with the amputation of the roots involves the danger of serious and permanent injury to a tree. As in the medical world it is a job for the specialist, and in any case consultation in the first place is the wisest course, because the trouble may be due to other causes which may be remedied without recourse to such extreme treatment. It is probable that the trees may not want root pruning at all, but the disuse or greater restriction of the knife in winter.

Tomato plants grown in a bed of soil in small greenhouses have now been removed, and the problem which presently confronts the amateur is the utilisation of the vacant space during the coming winter. Frequently no attempt is made to cultivate the ground, because of the absence of artificial heating, and the owner may not be inclined to incur the expense of providing an oil stove, nor be troubled with the care and attention which its management involves. The solution, therefore, lies in the direction of growing subjects which succeed under glass without the aid of artificial heat. Such conditions are ideal for the cultivation of daffodils, hyacinths, tulips and other bulbs, which will serve the double purpose of a floral display in the greenhouse and the supply of cut flowers for the home. In the event of a small collection being grown in fibre, these bulbs can also be used to replenish the bowls from time to time, and thus maintain a succession of bloom indoors. If the aim be to produce something out of season, the amateur may easily raise a crop of green peas for his Christmas or New Year dinner by sowing a couple of rows of an early dwarf variety, such as the Sherwood or Thomas Laxton.

ST. MUNGO.

WHAT OUR READERS SAY

CROCUSES FOR THE ROCKERY.

SIR,—I have only just read Dr. H. Stewart Wacher's article on "Crocuses for the Rockery" appearing upon page 526 of THE GARDEN. It is full of interest. Will you, however, allow me to question the identity of a few of the species described, and will Dr. Wacher forgive me for doing so?

Dr. Wacher's "Crocus cancellatus" cannot be the type form, which is white more or less striped with purple. It must, I think, be either the variety cilicicus or the much rarer white-anthered form cilicicus lilacinus. Its very early flowering suggests the latter, and I should have less doubt about this were it not that this form does not at present appear to be upon the market.

I do not know what the "C. corsicus" which flowers with C. speciosus can be. It can scarcely be the species named, for that flowers in late winter, and to the casual glance is not unlike a dwarf C. Imperati. What the "C. Korolkowi" with purple blooms in November is I think I can guess. If Dr. Wacher obtained it from the source I imagine he did, it is almost certainly C. Saltzmannii erectophyllus. The true crocus of Korolkow flowers in January, and is of the same greenish tint of yellow internally as the celandine buttercup and with the same high polish. Externally it is more or less stained, freckled or feathered with brown. Its colour contrasts strongly with the deep orange yellow of other species flowering with it.

Dr. Wacher's pale lilac "C. Olivieri" is puzzling. It might be so many things, but on the whole his description best fits C. minimus. The true C. Olivieri is a little yellow crocus which does not now appear to be upon the market. I usually receive for it either a deep yellow form of C. candidus or that C. suterianus which, under its synonym C. Aucheri, Dr. Wacher himself mentions. C. Olivieri differs from this latter mainly in possessing broader leaves and in lacking a certain brownish stain at the top of the corolla tube.

The "C. lævigatus," described as being similar to the lilac "C. Olivieri," presents much the same difficulties and possibilities. The true C. lævigatus is a white crocus, feathered with purple, and with a rich golden throat. It flowers early in October, is very dwarf, and in appearance a frail, delicate, fragile beauty. There is a major form, with slightly larger flowers faintly tinted with lilac, which flowers a month or so later in the year; and yet another form, the variety Fontenayi, of a bright lilac colour, very richly feathered externally, and flowering with me in December and January. Perhaps this is Dr. Wacher's plant, though I have never had it in bloom quite so late in February.—H. A. GREATOREX

SEPTEMBER NOTES FROM AN AMERICAN GARDEN.

SIR,—One of the most striking plants in bloom at present is the beautiful Clematis paniculata—a species which does not succeed particularly well in Britain; around New York, however, it

Digitized by Google

is extensively planted and allowed to ramble over every conceivable kind of support, and at this season of the year it is literally smothered with its pure white four-petalled flowers, which emit a strong hawthorn-like scent. As a subject for training over an arch it is ideal.

Euonymus patens is another useful September flowering subject—the small pale green flowers, although not conspicuous individually, are pleasing in the mass, and as the plant retains its leaves during the winter it is valued here, where broad-leaved evergreens are not so numerous as in Britain.

The various forms of Hibiscus syriacus do remarkably well in this part of the world, and at the present time they are adding colour to our shrubberies with their single and double white, red, blue, purple and striped flowers. In a more formal part of the garden are some shaped standards of this shrub which are clipped into shape in the early part of the year and allowed to flower on the current season's growth.

Among berried shrubs of note may be mentioned the well known snowberry (Symphoricarpus racemosus), now bearing its large waxy white berries at the termination of every shoot. The vivid scarlet fruits of the mountain ash (Pyrus Aucuparia) make a brilliant splash of colour only equalled by those of the pyracanthas. Lonicera tartarica has small red berries resembling currants, which, although not very showy from a distance, are interesting when a closer view of them is obtained. Other berry-bearing shrubs now in fruit are Cotoneaster moupinensis, C. divaricata, Viburnum dilatatum, V. Wrightii, V. cassinoides, V. hupehense, Lonicera pileata and Berberis emarginata. Berberis Thunbergii—the best of all the barberries in this locality and the plant used extensively in place of box for edging purposes—is carrying a good crop of fruit which will colour a little later; and so, also, is Cotoneaster horizontalis.

Mention must be made of Ailanthus glandulosus (the Tree of Heaven), the female trees, of which are bearing immense crops of seed which are now assuming bright autumn tints.

A splendid plant for rambling over a large boulder or training over an arch is Vitis heterophylla and its beautiful variegated variety; the berries produced by these are now changing from a deep purple to a bright turquoise blue, and either hue is equally attractive.

In the rose garden a few varieties are still making a brave show, among these Premier, Duchess of Wellington, Briancliff, Mme. Butterfly, Lady Alice Stanley, Caroline Testout and some of the dwarf polyanthas are most deserving of note.

Rudbeckias (including the purple-flowered R. purpurea), calliopsis, gaillardias, phlox, heleniums, asters, delphiniums, Eupatorium ageratioides, Sedum spectabile, Gazania splendens and Cimicifuga dahurica form the chief features in the herbaceous borders, and between these are planted our such things as cannas, helichrysums, zinnias (which thrive in the hot summers experienced here), petunias, cleomes, celosias, nicotianas, salvias, etc.

Although I should, perhaps, have included Buddleia variabilis in the shrubs, it is grown here among the herbaceous plants and is cut down to the ground each year, the result being that vigorous young shoots 4ft. or so in length spring from the ground level and bear the sweetly scented flowers at their termination. Buddleia variabilis is commonly known and listed as the Butterfly Flower, owing to the fact that butterflies and bees are continuously at work upon it. — GREYSTONE, *New York, U.S.A.*

TRAILING LOBELIA MAKES A FIRST RATE ROCK PLANT.

TRAILING LOBELIA USED AS A ROCK PLANT.

SIR,—This useful plant is well worth a trial on the rock garden. Its pale blue flowers and dark shining foliage form a fine patch during the summer. It also has the advantage of withstanding rough weather better than many annuals.—G. S., *Golders Green, N.W.4.*

A CHINESE ANEMONE.

Anemone hupehensis.

SIR,—Anemone hupehensis is a Chinese form of A. japonica. Compared with the type plant, it is more dwarf and flowers from two to three weeks earlier. The flower is an uncommon shade of pink, with a suspicion of pale mauve, and the reverse prettily shaded with a deeper pink. The general bearing of the plant is most attractive, and it is a free bloomer. The plants illustrated have been flowering for about eight weeks. It should be a useful subject for the semi-wild or woodland garden, as well as for the herbaceous border. Here, it is growing in a shrub border in partial shade.—D. E. D., *Moniaive, Dumfriesshire.*

A CHINESE FORM OF THE JAPANESE ANEMONE, A. HUPEHENSIS.

ROSE EXPERIENCES THIS YEAR.

SIR,—Having recently referred to "New Roses Worth Noting," it may, perhaps, be of interest and serve somewhat as a guide to those intending to grow roses if we consider the behaviour of some old-established favourites during the recent wettest season for years past. First of all, a word of warning is necessary to beginners not to be in too great a hurry to commence planting.

In this district the ground is much too wet, and the better plan will be to dig a trench and lay the trees in it in a slanting position, drawing the soil well up, and leave them until the ground becomes drier and more friable. In the meantime the trees will take no harm in their temporary home, and nothing will be lost by waiting, whereas to plant while the soil is sticky is to court failure, and is not giving the trees a fair chance.

Among the bushes I have had for some years, none has done better than Betty; in fact, it has never shown to such advantage either in quantity or quality of blooms. In contrast to this another old favourite, Mons. Paul Lede, has never done so badly, many of the blooms balling and others being ill-formed. Of the yellows, Mabel Morse did not bloom until the middle of July, but has since made a lot of new wood; Florence L. Izzard, Golden Emblem and Christine have been up to the average, although the blooms of the last named have been a trifle smaller than usual. Margaret Dickson Hamill, Gorgeous and Clarice Goodacre have all been disappointing, the latter balling badly. Red Letter Day has been very floriferous and appears to have revelled in the rain, while K. of K. has had fewer flowers which have also lacked the brilliancy of former years. Isobel has done exceedingly well, the first blooms being of remarkable size, and at the time of writing (October) is still producing fine blooms. A rose that always does well whatever the weather is Independence Day, which bears an abundance of perfectly shaped blooms, and this year has proved no exception to the rule. An old rose that cannot be dispensed with is Pharisaer, which still competes successfully with the modern varieties. Others that have done well are Sunstar, Mrs. Pearson, W. F. Dreer, Los Angeles, Ophelia, Mme. Butterfly, Betty Uprichard, Irish Fireflame (bush and rambler), General McArthur and Colonel Oswald Fitzgerald; while among the comparative failures have been Harry Kirk, Marquis de Sinety, Sunburst, Lady Pirrie and Miss Alice de Rothschild, the latter balling very badly.—R. C., *Derby.*

FRUIT AND KITCHEN GARDEN

Planting Raspberries.

PROVIDED the conditions of soil and climate are favourable, raspberry canes may be planted from now onwards in ground that has been well dug and liberally manured. The R.H.S. recommend that planting should be done on Lord Mayor's Day, November 9th, and the canes cut down the first year on Candlemas Day, February 25th. Such specific limitations are unnecessary, as planting may be carried on throughout the winter in mild weather and the canes cut back to 12ins. or 15ins. either in February or at the time of planting. While the raspberry is not fastidious as to soil and situation, best results are obtained in medium loam and an open situation. In small private gardens it is a common practice to grow raspberries in a single line as a screen or dividing fence, but the system of growing the bushes in rows in bed or border also finds favour. In the latter case the distance between the rows should not be less than 4ft., and when planting the canes 3ft. to 4ft. apart the roots should be spread out to their full length. As is the case with the planting of roses, a little fine soil scattered over and around the roots has a beneficial influence on the root system. Various methods of training the canes are practised, and the reader can choose between the wire trellis and the practice of growing each plant on a single upright stake as is followed in field cultivation. Good varieties for summer ripening are McLaren's Prolific, an early cropper and free bearing; Storrie's Invincible, a large dessert fruit; and Superlative, a well known and desirable sort. These are all red summer-fruiting varieties, and if a yellow-coloured raspberry is wanted, either The Guinea or Yellow Antwerp is fertile and well flavoured. Lloyd George only succeeds in favoured localities north of the Tweed.—K.

Repotting Fruit Trees.

FRUIT trees that are grown and fruited in large pots require special attention. There is only a small space for the roots and their larder—the soil. The latter must be of the best quality, full of fibre, of a lasting nature. The drainage of each pot should be quite sound—that is, it must not be blocked by soil or the roots of the trees. Several times each year it is necessary to examine the drainage and especially in the autumn, when the leaves have fallen. Trees that are found to be pot-bound should be shifted to larger pots or be top-dressed if larger pots are not available. Deeper top edges may be made by placing hoop-irons there or by fixing broken pieces of pots round the sides and connecting the pieces with a cement mixture—1 part cement to 2 parts of fine sand.

When repotting a tree, provide clean dry pots and crocks. As there is not much space for soil, use as few crocks as possible, but let them be strong, hollow and carefully placed. Such will answer the purpose better than many crocks badly placed. On the crocks place some of the most fibrous of the turves; firm these with the potting-stick, then arrange the old ball of soil and roots on them and fill up with the general mixture, making all new soil quite firm. Do not use the potting-stick on the old ball of soil and roots. Remove the old crocks, of course. A good single handful of bone-meal to each bushel of chopped or pulled turves will be ample in the way of manure. Directly the trees are potted arrange them on a firm bed of ashes where the base is dry; pack dry ashes between the pots as high as their rims, then tightly pack short, dry litter on the surface of pots and ashes to a depth of 9ins. A few days after the potting, water thoroughly once or twice.—CHRISTCHURCH.

Treatment of Ripe Grapes in the Greenhouse.

FROSTS, fogs and stagnant atmospheres are very bad for grapes that are ripe and must be kept for a time on the vines. The varieties Muscat Hamburgh and Muscat of Alexandria require some artificial heat or the berries will decay. The variety Gros Colmar needs such heat, not only to prevent decay of berries but to get them well coloured, a task that sometimes tries the skill of very experienced cultivators. The variety Black Alicante will keep better than any other in a cool temperature provided the atmosphere is not constantly moist. If subjected to a high temperature after the berries are quite matured the latter will sometimes turn soft and even decay. On a bright, sunny day the top ventilators should be opened gradually to 4ins. in extent, and the house should be closed one hour before sunset, then the internal temperature will be raised several degrees. It is only necessary to have the pipes just "warm to the feel" with a steady fire banked-up at bedtime and the grapes should keep well. The following morning note whether there is condensation on the berries or whether they are quite free from moisture. If there is moisture on them, disperse it gradually by opening the top ventilator a little. If opened very wide the inrush of air would cause a chill and thus shorten the keeping qualities of the grapes. Path and borders must be dry on the surface.—HANTS.

A Note on Apple Stocks.

MANY readers will shortly be ordering fruit trees for planting this autumn and winter and no doubt some will be greatly puzzled by certain figures behind the name of the apples. For instance, Bramley's Seedling, Type IX and Type II. These figures refer to the stock on which the variety is worked. No doubt many readers know that the East Malling Research Station has, for a number of years, been examining and experimenting with fruit-tree stocks. The apple has claimed most attention, because it is the most widely grown of our trees and also because the different stocks have been segregated more than with the other fruits.

Until the Malling Station undertook the great work of classifying and testing apple stocks, we were accustomed to think of there being two classes of stocks, namely, paradise (for dwarf trees) and crab or free stocks (for large growing standards). It is true that some of our leading nurserymen had selected special types of paradise stocks of uniform growth and were working only on these, but often a batch of trees of the same variety worked on so-called paradise stocks, varied enormously in their strength of growth and cropping capacity.

When Mr. Hatton commenced his experiments, stocks were collected from every possible source at home and abroad, were carefully classified and after several years work with these stocks a list was published with full descriptions of the types found and notes on their value. Altogether some twenty different types of paradise were described, varying in vigour from very weak growers to some which grew quite as strongly as the crab. The most suitable types of these stocks are now in use by the trade and the figures referred to at the commencement of this note relate to the type of stock on to which the tree is budded or grafted.

The types in greatest use are numbers IX, II and I, and this note is intended to outline their characters as far as they influence the growth of the tree.

Type IX (Jaune de Metz paradise) is a very weak grower and therefore is much in demand for cordon trees and quite recently for very small bush trees in sheltered places. Its great value lies in its tendency (owing to its weakness of growth) to produce early crops. It is doubtful if it will remain in good healthy condition for more than twenty years, although I recently heard of a tree on this stock fifty years old. Of course, much depends on how the tree is treated with regard to manure, spraying, pruning and thinning.

Type II is a rather brittle-rooted stock, rather more vigorous than Type IX. Perhaps the most useful stock for bushes in amateurs' gardens, as it does not, under careful treatment, make too large a tree and it commences to fruit quite early in its career. It is scarcely suitable for exposed places, especially for strong growers, such as Newton Wonder and Bramley's Seedling, which are better grown on Type I (broad-leaved English Paradise), which is stronger in growth and has a better roothold for heavy topped trees in exposed positions.

I have, in writing this note, had in mind bush trees, for really bush and trained trees, such as cordons, espaliers and fan-trained trees, are, to my mind, the only suitable trees for the amateur to grow, unless he has a grass orchard.

To sum up—Type IX for cordons, Type II for bushes, especially in sheltered spots, and Type I for large bushes in exposed situations. Of course Bramley's Seedling (a very strong grower) will always make a far bigger tree than Stirling Castle (a weak grower) if worked on the same type of stock; in fact, I doubt whether Stirling Castle on Type IX would make sufficient growth to remain in health.—N. D. H.

The Rotation of Crops.

THE following general hints may prove useful to cultivators who have recently taken a practical interest in growing vegetables. If possible, you should ascertain what kinds of crops have been grown in the old garden in recent years. This would help very much. If it is a new garden, then a clear beginning can be made and you can crop according to a set plan to a great extent. It is rarely advisable to grow the same kind of plant on the same plot in two successive years. If they are quickly maturing subjects, even, an intervening crop of different character should be grown, and one that soon matures, too.

Fibrous-rooted plants, such as savoys and cauliflowers and the others which are included in the brassica family, should be followed by tap-rooted or bulbous plants, as the brassicas are great exhausters of the soil and should not be grown at all in a poor rooting medium, as they would not afford the cultivator an adequate return for his labour. Turnips, potatoes, carrots, beet and parsnips are suitable for following or preceding, preferably the latter, as their deep cultivation has a beneficial effect in preparing the soil for the brassicas. Surface crops, such as lettuce, onions and endive, may follow. Such crops as artichokes and asparagus, seakale and rhubarb should be left out of the rotation scheme, as it is advisable to prepare ground specially for them and in a specially selected part of the garden. Before any planting of these is done the ground must be deeply trenched.—GEO. GARNER.

Forcing Chicory.

THE first batch of chicory may be forced now. Forcing in the true sense is not suggested here, as all artificial heat can be dispensed with. So those who do not possess hot-beds or heated structures may obtain nice white chicory. Lift the strongest roots, twist off any foliage and then place the roots, almost touching each other, in deep boxes

Digitized by Google

or in heaps of soil in cellars or sheds. Finely sifted soil is the best to use. One watering should be sufficient. Of course, chicory can be forced in boxes in the greenhouse, but a high temperature is not advisable as it does not conduce to good flavour. Darkness is essential to perfect blanching.—G. G.

Planting Horse-Radish.

HORSE-RADISH is a plant to keep in a special corner of the garden owing to the way in which the plant spreads to positions where it may not be wanted at all. Quite a small bed will, with reasonable treatment, produce a good many "sticks," as the roots are called. The soil should be deeply dug, and it is better that it should be on the light side. In the case of heavy land it is well to work in sand, road grit, etc., fairly freely. In soil of this nature horse-radish not only grows better, but it is much easier to dig up the roots. In making a new plantation the crowns may be planted a foot deep in holes made with a crowbar, the openings finally being filled with light rich soil. Another way is to plant the long, straight pieces of root, placing these in rows 18ins. apart, at intervals of 9ins. in the row. Before planting, the fibrous roots should be rubbed away, as long, straight stems without forks are the best. Horse-radish may be planted any time between November and March when the weather is open.

Apple Trees and Fungoid Disease.

AMONG fungoid diseases that attack apple trees, that known as canker is quite the worst. After the fall of the leaf, growers should examine their trees and take prompt measures to deal with the trouble if it appears. Although all kinds of apples are liable to canker, some varieties, such as Ribston Pippin and Lord Suffield, are much more prone than others. The presence of canker may be traced to various causes, such as wet and poor soil, abrasions of the bark, rubbing of the branches and, especially, from the wounds caused by the attacks of the woolly aphis. When planting time is on, it should be remembered that canker may be largely prevented by choosing suitable varieties, such as nurserymen would recommend, and the setting of the trees on soil of good quality which is well drained. If the appearance of canker is recognised at an early stage a good deal may be done by scraping the diseased parts and then making an application of Stockholm tar. Another plan is to rub the affected parts with a solution of sulphate of copper in the proportion of a quarter of a pound to every nine gallons of water. This method is best carried out in the middle of the winter. Where branches are very badly affected, the only way is to cut these right out, taking care to burn them, so as to destroy the spores of the fungus. When winter pruning is in progress, remove, or tie up, any branches which are tending to rub one against the other. If there is reason to believe that poverty of the soil has something to do with the appearance of canker, the following mixture, to be applied in mid-winter, will be found to be very beneficial: 6lb. of superphosphate, 5lb. of nitrate of potash, ½lb. of sulphate of iron, 2lb. of sulphate of lime, 1½lb. of nitrate of soda. Apply the mixture at the rate of 4 oz. per sq. yard.

MAKING A PROPAGATING FRAME

EVERY gardener feels the need of some kind of plant propagator. It is far more interesting to raise one's plants from seed and in some instances more satisfactory. Many amateurs possess a small, unheated glasshouse. It may be impossible for them to maintain a reasonable temperature owing to the fact that all day they are away at business. Recent articles have shown how many plants may be grown in such structures, for instance, many amateurs grow tomatoes in unheated houses, purchasing the plants when ready for final quarters. The use of a propagator would provide such gardeners with plants for greenhouse decoration or bedding purposes. To those who possess no greenhouse, a propagator of the form shown would be useful if the gardener also had a cold frame. Quite a simple form of propagator can be made from an old box, with half of one side removed (Fig. 1). Two battens are screwed to the end of the box. On these battens a strong zinc or iron plate rests. This plate has a hole in it and above is placed a tin (with lid) containing water, beneath is an oil lamp. The top of the box is covered with sheets (or one sheet) of glass. Round "shortbread" tins, 1in. or 2ins. deep, are quite suitable for water containers. With a lamp of suitable size, it is possible to maintain a temperature of 60 degrees in such a small propagator. Fibre, etc., is placed on the plate and pots containing seeds and cuttings are plunged into it. This arrangement, however, is rather crude and many amateurs will prefer to make something more worth while. Figs. 2 and 3 show propagators of which no gardener need feel ashamed and which will render very useful service, paying for themselves over and over again. A glance at the rough sketches shows their simple construction. The size, of course, will be determined by what the propagator is expected to do. A frame mounted on legs is made, into which is placed the "heating arrangement." The heater is the most difficult part to construct and in most instances it will be better to give the work to a local plumber or tinsmith, or to purchase a ready-made heating apparatus from firms who specialise in this kind of work. The type of heater required should be as simple as possible and should consist of lengths of ¼in. or ½in. copper tubing together with a T-piece which connects the lengths of tubing, and also a funnel-shaped arrangement with which the lamp is adjusted. A sheet iron or zinc trough, from 2-3ins. deep, is then made. The funnel or diminisher is unscrewed and T-piece and tubes soldered in trough. Two filling tubes are fitted into lid of trough and made fast. The heating arrangement is now ready. It should have been stated that the tubes from T-piece should project a little (three-eighths of an inch) through trough and all joints be made watertight. The rest is simple. The sketches make clear how the thing works. A lamp is placed under the funnel connected with the heating arrangement, the tank is filled with warm water—the lamp lighted and in a short time the temperature of the propagator will be at least 60 degrees. Just a word about lamps. The most suitable type of lamp is one with an incubator lamp burner. The great advantage of these burners is that they are *practically* fumeless. These lamps are now readily obtainable in various sizes from horticultural sundriesmen who advertise in this journal. Also, if a container that holds half a gallon of paraffin, is obtained, the lamp will burn for a considerable time. The burners are obtainable in all sizes from ½in. to 2ins. or 3ins. When all is fixed up, fibre, leaves, etc., are packed inside the frame, into which pots of seeds, cuttings, etc., are plunged. The end of the propagating case should have an outlet for the hot air. For use inside a cool house, Fig. 2 is useful; Fig. 3 may be placed in a light shed, or even outside. However, if used outside, the bottom of stand must be boarded round, with air holes left near the base, and a door fixed in order to adjust the lamp,

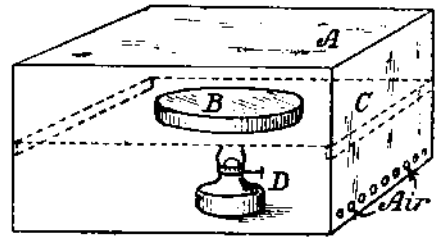

FIG. 1.

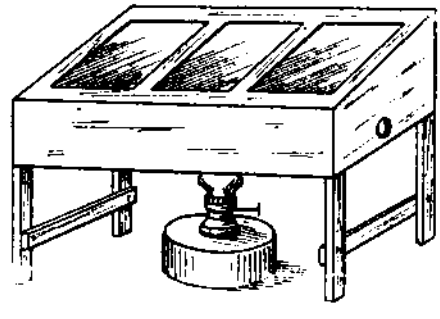

FIG. 2.

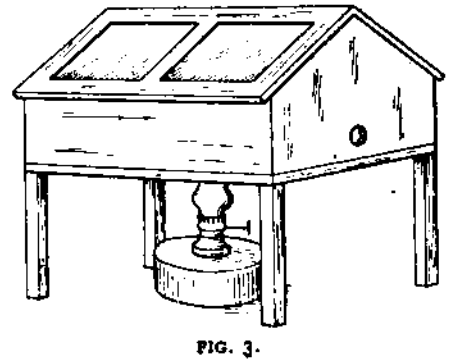

FIG. 3.

The uses to which these may be put are many. If the propagator be made 18ins. deep and no less than 4ft. 6in. long it may be used as a miniature greenhouse, and it will be found possible to force bulbs in it—a few pots at a time—thus keeping up a supply for the table. The size of the tank for a propagator 4ft. 6ins. long should be 2ft. 9ins. by 3ins. deep. This, heated with the lamp already described, should keep up an even temperature round about 55 to 60 degrees. An alternative plan is to make a tank 2ins. deep and let it go the full length of the propagator. For a tank 3ins. deep, the size of the heating tube must be half-inch; for one 2ins. deep, three-eighths will do. Copper is, of course, best, but brass or iron will answer. In such a structure as has been described the writer has seen bulbs forced for winter table decoration, and in a propagator of this type tomatoes might be raised, as well as many seeds requiring a somewhat higher temperature than the average amateur can maintain. A good many amateurs keep their greenhouse at a very high temperature during winter, with the intention of germinating seeds or propagating certain plants to the detriment of certain flowering plants (primulas, cinerarias, etc.). The amateur may easily work out dimensions of the propagator best suited to his own needs. There is no reason why two lamps or at any rate two burners, should not be used, and the propagator made into a miniature glasshouse for those who wish to force certain plants. PRACTICUS.

OUR SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, 20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with each enquiry.

We have selected the following enquiries, with their answers, as being of more general interest, and therefore worthy of publication.

Diseased Madonna Lilies.

Kindly tell me what is the matter with the two Lilium candidum bulbs I have forwarded to you for examination. Apparently all fibrous roots have been destroyed. They are planted in a long, narrow border, where the bulbs are partly shaded by other plants. I also notice they were planted in sand. There are several clumps of this lily in the border, and in early summer they all appear of normal growth, but gradually begin to discolour in the leaves until they look all dried up. This trouble starts at one end of the border and there are two or three clumps at the far end which are not affected.—C. F., Scarborough.

The bulbs sent for our inspection are attacked by a fungoid disease, known as Botrytis cinerea. This lily is very subject to this disease, especially in such an adverse season as we have experienced. The foliage and stem are first affected, the disease in bad cases spreading to the bulbs. It would be unwise to plant them again, although you could lift and dry them for a few days, and then dust them thoroughly with flowers of sulphur before planting them on fresh ground. During the growing season you should try spraying with a solution of liver of sulphur, at the rate of one ounce to three gallons of water. A little soft soap added to the mixture would render it more adhesive. Do not cut off the old stems while they are green; as they dry up you can gradually cut them down.

Apples for a Small Garden.

I have a small garden rather enclosed, and am desirous of growing an apple tree. Would you please tell me how to prepare the ground; when would be the time to plant same; which kind you would recommend? I, personally, am rather disposed to try a Bramley Seedling, but do not know if they are self-fertile and also if the soil (which is clay, pure and unadulterated) would suit it.—E. P., Honor Oak Park, London.

The ground should be thoroughly trenched, and as you say it is a heavy clay, we should advise leaving it exposed to the action of the weather and planting in the spring. Incorporate some good loam and leaf soil when planting. In this case we advise you to plant your tree in the spring, but usually the autumn is the best time to do this. Bramley Seedling is only partially and rarely self-fertile. Self-fertile varieties are Stirling Castle (early, culinary), Early Victoria (culinary), Lord Grosvenor and Lord Derby. Allington Pippin and Worcester Pearmain are partially self-fertile.

Mealy Bug on Vines.

Would you kindly advise me as to the best treatment for mealy bug on a Lady Downes vine. I took over this place last year, and in the winter washing I scraped the rods in the usual practical manner and painted them once with Gishurst's Compound, then again with a mixture (which I had used years before with success on other vines) consisting of blue clay, tobacco and sulphur. I also washed all the woodwork of the house with caustic soda and removed about 4ins. of soil from the border. All the operations were done in their due season. I may say that the vines have been in a bad state for years, with vermin. Could you tell me of anything with which to spray the bunches that will not do any injury to the berries, as it seems the only way? I have tried methylated spirit, but I would like to take the sticky substance from the fruit. I am a gardener, but have never had such a bad experience of pests before.—J. D., Fife.

You have followed the right course in trying to get rid of the mealy bug on your grape vine. The trouble is that odd insects do escape the applied mixtures and then, in spring, when natural heat comes again, they soon increase in numbers. The only thing to do is to treat the rods with the Gishurst Compound again this winter, and to look out for and destroy odd insects that may be found next spring. It is not possible to apply any remedies to the bunches. You can only syringe them, when cut, with clean water. Try to prevent the mealy bug infesting the bunches.

Dying Back of Apricots.

I enclose a branch of an apricot tree on a wall here. The whole of the upper portion of the tree has shrivelled up and died, like the enclosed specimen. It began about three months ago. The lower portion of the tree and some of the side shoots seem unaffected. A red currant on the same wall has gone in much the same manner. Can you tell me the cause of this and what you recommend as a cure?—C. M., Yeovil.

The dying back of apricot branches is a trouble that has mystified gardeners for many years. At the present time there is still no definite cure or means of preventing their dying-back. It is generally found, however, that the stronger the tree grows the more liable it is to suffer; and again, the harder the tree is pruned the more prevalent is the die-back. Root-pruning in the first few years and light pruning of the branches seem to make for healthier trees, and it is essential that the border in which the tree grows should be well supplied with lime in some form or other. Whenever a branch dies back it should be cut clean away, beyond any dead or sickly part, at once, and burned. The death of the red currant branch is not likely to be due to the same cause. The branch should be cut out at once and a new young shoot trained up in its place. In practice it is best to remove the old branches in a red currant bush as soon as they show signs of weakening, taking out a branch every year so that the bush is continually being refurnished with young branches.

Treatment of Clematis.

In the spring I purchased two Clematis Henryi, planted them against a wall facing south, where they started off all right and each sent out about half a dozen buds which came to maturity, since which time all the leaves have dried up and dropped off. Now one is completely bare, and the other has broken into sickly growth at the top. What do you advise—to cut them down near to the ground, or to leave them to chance? I have a Jackmanni, on the same wall, which has done splendidly and is at the moment covered with flowers. Is Henryi of the same nature, or does it flower on the old wood? Is it likely to flourish on a wall facing south, or could you recommend another good white which would?—W. R., Ormskirk.

Clematis Henryi belongs to the Lanuginosæ section, flowering successionally on short lateral summer shoots. Pruning should take place in February, and consists of removing the weak, straggling and overcrowded branches C. Jackmanni belongs to the Jackmanni section, which thrives best when the previous season's growths are cut hard back during the winter or early spring. As a rule, a south wall is considered too hot for clematis—west or north-west is better; but we have had no hot sun this year sufficient to split the bark. Probably the violent winds have swayed the stems backwards and forwards, causing the bark to split, and there is probably also damage to the stem. The only hope is to cut the plants down to where the stem is sound and see if they will make new shoots.

Roses for a Hedge.

My neighbour and I have agreed to replace a well-grown dividing hedge of privet by roses. The ground is yellow clay and is at the back of the houses, which on that side have a south-south-eastern aspect. There is a laburnum tree near the middle which I have already lopped and a lime tree at one end which I intend lopping this October (both on my side of the hedge); indeed, the privet happens to be in my garden, as it was planted on one side of a low wooden fence (which has since disappeared). The hedge is now about 3ft. 6ins. high (after drastic cutting). I hope to move the privet soon and then to place in open trench a load of stable manure, to be kept exposed until rose-planting time in November. Would it be feasible to plant hybrid perpetuals of strong growth, and if so, would you kindly name varieties and number to be planted in 18yds. Alternatively, climbers have been mentioned, but these entail rustic work. On the other hand is it practicable to obtain a rose hedge which will present a pleasing appearance in winter. We are about twelve miles west of Kinder and the Peak District and stand about 300ft. above sea level. It is therefore somewhat exposed. One desire I have in mind and that is to grow really good roses for cutting, if that is possible. The beds on each side have a decided slope and this we hope to flatten somewhat.—T. H., Stockport.

As the roses are to form a hedge, we suggest the effect would be much more pleasing if you planted only one variety, either Gruss an Teplitz or Zephyrine Drouhin. These are perpetual flowering. We should not recommend hybrid perpetuals as they are not free-flowering enough. If you prefer additional sorts, plant also Frau Karl Druschki, Hugh Dickson, Prosperity, Pax, Moonlight, Vanity and Fellenberg. The bushes should be planted 3ft. apart for a hedge.

Maggots in Raspberries.

The fruit on my raspberry canes is very maggoty this year, and I have noticed that the wetter the year the worse the pest is. Books I have consulted describe the treatment for various fungoid diseases, as also for a stem-burrowing grub, but I fail to see any reference to the prevention of infestation of the fruit with larvæ.—A. S., Bradford.

It is almost certainly the raspberry beetle that is spoiling your raspberries. The beetle maggots (larvæ) feed in the berries and render them unfit for use. Unfortunately, no really satisfactory method of dealing with this pest has yet been discovered. Perhaps the best measure is to run fowls among the canes, since they devour the insects readily in all stages. Many gardeners find it worth while to tap or jar the canes periodically while in flower, causing the insects to fall within reach of the fowls. If this is impossible, the beetles may be shaken off the canes on to newspapers or sheets laid on the ground, and destroyed. Under experimental conditions spraying the open bloom—where the beetles are egg laying—with lead arsenate has given promising results, but it is open to objection, firstly on account of poisoning bees, and secondly because the length of the flowering period would render several sprayings necessary. Trapping in spring, when the canes are in flower, and the employment of fowls, seem the most useful remedial measures.

ASTILBES

106 Collection of **12** varieties for **96** Carriage Paid.

ASTILBES are one of the brightest flower families of the year and there is no special difficulty in growing them. We exhibit them in splendid form off very poor ground and with no special facilities or effort of any kind. They will thrive in any ordinary border positions on anything excepting only chalk and very light land. They flower in July and August in most shades of pink and red, from clear pale shell pink in the variety Pink Pearl to a rich glowing red in the variety Princess Mary. The foliage is nearly as beautiful as the flowers—prettily formed, dwarf and compact in growth, full of colour and mostly glossy. Height of flower spikes varies with varieties from about 2½ft. to 4ft. Astilbes are worth growing; we have the highest opinion of them—and now is the time to plant them. The following collection is well chosen for both variety of colour and form and is specially priced at a low figure:

AMERICA, lilac rose; **BRUNHILDE**, creamy pink; **CHINENSIS**, pale pink; **GRANDIS ROSEA MAGNIFICA**, deep rose; **GUNTHER**, clear pink; **KREIMHILDE**, salmon pink; **MONT BLANC**, creamy white; **PRINCESS MARY**, rosy crimson; **RUBELLA**, flesh pink; **RUBIN**, crimson; **SIEGFRIED**, salmon rose; **VESTA**, rosy lilac.

THE GARDEN

VOL. XCI.—No. 2918. NOVEMBER 5, 1927. PRICE TWOPENCE.

SOME GOOD AUTUMN PLANTS IN A SMALL GARDEN

The Outcome of this Year's Experiences.

ONE of the most striking features in the little garden this autumn has been the gorgeous display made by the tall heleniums, which seem to have enjoyed the rainy season, for never have their flower-heads been larger nor their colours richer. They include Riverton Gem, deep red streaked with gold; the scarcely less brilliant H. autumnale rubrum, the fine yellow ones H. Gartensonne and Riverton Beauty and the newer Bronze Queen. A group of these heleniums combined with Rudbeckia lacineata—the single type, not the double variety which blooms earlier—and kniphofias, of which Mount Etna and H. G. Mills are two good recent introductions, with Rudbeckia speciosa, montbretias and perhaps some deep yellow chrysanthemums as front row plants, makes a glorious mass of colour in September and October, especially if seen against a background of dark shrubs. All the heleniums, including those of the dwarf pumilum and cupreum types, are invaluable for cutting.

As many Michaelmas daisies as space will permit are grown in the little garden. They include some of the best of the Novæ Angliæ, Novi-Belgii and amellus sections—among them Barr's Pink, Little Boy Blue, Little Pink Lady, Climax, Wonder of Colwall, Beauty of Ronsdorff, King George and Perry's Favourite—and room is also found for such species as Aster acris, whose pretty mauve flowers almost conceal the feathery foliage in October (the dwarf white variety of this is a very dainty thing, by the way); A. tradescantia, one of the latest to bloom; the Winchmore Hill variety of A. Thomsoni, A. corymbosus and A. diffusus horizontalis, the "Farewell Summer" of old cottage gardens, with its neat sprays of clean-looking tiny red and white flowers. Aster grandiflorus, the Christmas daisy, is here too in spite of the painful fact that in nine seasons out of ten its handsome violet-purple flowers are spoilt by frost. Both Pyrethrum uliginosum and the Boltonias B. decurrens (white) and B. asteroides (pale pink) occupy too much room for a small garden, but they are so useful for cutting when the rest of the autumn flowers are nearly over that they are allowed a place in an out-of-the-way corner without much sun where the pyrethrums, if not the boltonias, are quite happy. Far more suitable for a little plot of ground is the yellow ox-eye, Buphthalmum salicifolium. Its round, compact bushes have been a mass of gay yellow blossoms during the summer.

Clematis orientalis on a bit of wall behind the rockery has done well this season, and is still a sheet of golden blossoms like tiny lanterns, interspersed at this time of the year with fluffy, silvery grey seed-pods. It seeds itself freely, although the young plants are slow in starting. Close to the clematis on the wall is a good specimen of Cotoneaster horizontalis with a splendid show of scarlet berries in their setting of glossy green leaves, and another of that quaint shrub with grey-brown, white-backed leaves, Corokia cotoneaster.

On the rockery itself there is not much to note, but Crocus speciosus is thrusting its big purple-blue orange-anthered flowers up through patches of Campanula pusilla alba still dotted with some little white bells. Planted thickly under almost any of the dwarf campanulas, or of the saxifrages of the "mossy" class, this autumn-flowering crocus makes a most beautiful edging for a bed or border and deserves to be grown much more extensively than it is, especially as the bulbs are not expensive. The soft rose-pink of several colonies—mostly self-sown—of Cyclamen Neapolitanum makes other pleasant touches of colour, while the autumnal tints of Ceratostigma plumbaginoides (which, to quote Mr. E. A. Bowles, "we used to call Plumbago Larpentæ and were quite happy in so doing while we knew no better"), Berberis Thunbergii, the foliage of some of the hardy geraniums and Cassinia fulvida provide a stronger note. There are some good clumps of Sedum spectabile, too, but they have bloomed so late this year that we have missed the pretty sight of the Red Admiral butterflies feeding on the big pale pink flower-heads. Sedum spectabile Brilliant is a brighter pink than the type, and decidedly more attractive than S. s. atro-purpureum.

The autumn tidying-up which all gardens must have is specially necessary in a very small one which gets quickly overgrown. Annuals must be pulled up—their flowering season has been a long one in most cases—to make room for the spring bedding in which in this particular garden the gay little double yellow wallflower Harpur Crewe, grown from last year's cuttings, will be used freely, sometimes combined with mixed cottage tulips, sometimes with Myosotis Royal Blue or dark red polyanthus as a carpeting. Clumps of rampant-growing things, such as Senecio tanguticus, Campanula glomerata, Michaelmas daisies of the Novæ Angliæ and Novi-Belgii sections, most varieties of helianthus and the Japanese anemones will need drastic reductions. An exception is made in the case of Nepeta Mussini, the old stems of which are always left to protect the roots.

This Week's Work

For Gardens in the South and Midlands.

Plant out wallflowers, polyanthus and forget-me-nots.

Lift dahlias and gladioli and store in a frost-proof shed.

Plant gooseberries, currants, loganberries and all hardy fruit trees.

Tie up and train all climbers on walls.

Lift rhubarb and seakale for forcing, and make a sowing of broad beans.

Begin renovation work in the herbaceous border.

Clear up the rock garden and cut back overgrown alpines.

Provide protection for all tender plants.

Plant out May-flowering and Darwin tulips.

This Week's Work

For Gardens in Scotland and the North.

Dress established rose beds with basic slag.

Plant myosotis, sweet william and wallflowers.

Lift dahlia and gladioli roots.

Cut down border chrysanthemums.

Plant deciduous flowering shrubs.

Erect new arches, pillars and pergolas.

Transplant rhubarb roots for forcing.

Strike cuttings of black currants.

Plant dwarf, standard and rambler roses.

Begin alterations to borders and beds.

Continue planting daffodils and tulips.

Start trenching heavy land.

ASTILBES AND SPIRÆAS FOR THE BORDER

NEVER before in the long history of gardening has there been such a wide variety of new hardy flowers from which planters might choose when preparing plans for the fast approaching planting season. Among these, few show such a marked advance as the astilbes, which, formerly somewhat on a par with the spiræas, now far surpass them in numbers, and beauty of colour, vigour and attractive foliage.

This remarkable development is largely the result, one may even make bold to write entirely, due to the introduction of the violet-crimson flowered Astilbe Davidii from China. Beginning by crossing this with Astilbe japonica and A. floribunda (Spiræa astilboides), so popular for greenhouse culture, the work of crossing, recrossing and selecting has gone on until to-day we have plants which in habit, colour and beauty, we should have described twenty to twenty-five years ago as impossible to attain, at least in such a short period of time.

Formerly associated more with the bog garden and waterside, the newer varieties of astilbes are fitted to take their place with the phlox, delphiniums and other hardy perennials in the mixed flower borders. The shades of pink and rose are a distinct and pleasing colour addition, the season of blooming extending from July to September.

For cultivation in pots the two early hybrids Peach Blossom (flesh rose) and Queen Alexandra (light rose) are well known. The newer hybrids are also very valuable plants for greenhouse decoration, the essential conditions, as with Astilbes japonica and floribunda, being abundance of water and liberal supplies of liquid manure during the growing season. If the conditions are at all dry in the greenhouse stand the pots in saucers of water.

Soil and Position.

The astilbes and spiræas are invaluable subjects for planting by the waterside, in the bog garden, in damp half-shady borders, and in the moist open woodland or wild garden. They are equally attractive and grand plants for the perennial and mixed flower borders, where they thrive and flower freely in well cultivated ground. The two conditions to avoid are a hot, dry, sandy soil and very chalky ground.

Few hardy perennial plants repay the grower better for the deep cultivation and manuring of the ground previous to planting. Follow this up with liberal mulchings of old decayed manure and leaf-mould, with soot or wood ash mixed in, if available, in early summer. Failing this, give plenty of weak liquid manure during the growing period to groups in the borders, and use the hoe freely. Especially is watering and hoeing necessary in dry weather, as few plants suffer more quickly from lack of moisture.

Astilbes and spiræas are very valuable hardy plants for the borders of small town and suburban gardens, in fairly light positions, but somewhat shaded or sheltered from the sun by houses and fences. They should be planted when the soil is cool and moist. The grower should liberally cultivate and manure the ground. Both spiræas and astilbes are readily

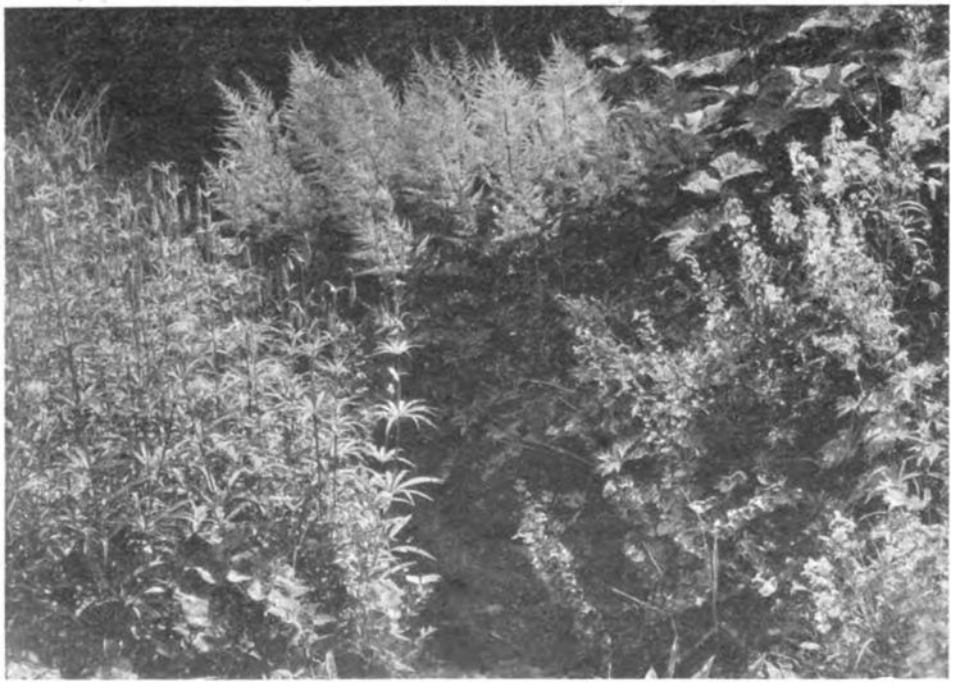
Increased by Division

in late autumn or spring. Planting and replanting may be carried on through the winter whenever weather and soil conditions permit, but in practice the best results are usually obtained when planting in the flower borders is completed by mid-November.

Planting in large groups and masses by the waterside and in the bog garden may be done equally successfully in early spring. The positions being naturally moist, there is not the same possibility of the plants suffering in the event of a dry spell in spring following immediately after the planting of the roots. The present-day race of new varieties of astilbes give a wonderful range of colours from pure white and creamy white through innumerable shades of pale and deep pink to rose, rosy crimson and purple.

The twelve varieties shown in the coloured illustration on the front cover of this week's issue include some of the best and most distinct of the newer sorts. Amethyst is a very distinct and beautiful astilbe with violet-purple flowers borne on strong branching panicles up to 3ft. or more in height. Granat is one of the brightest colours to date, quite a rich red, the plant 2½ft. to 3ft. high. Rubin is another effective colour, a rosy crimson, vigorous in growth, 3ft. or more tall. Grandis rosea magnifica is a tall variety with attractive deep green foliage and dainty pale pink blossoms on vigorous stems up to 4ft. or more in height. Its flowering season extends into September. Gunther is another tall-growing sort, the pink flowers a deeper shade than the last named on stems 3½ft. to 4ft. or more in height. Pink Pearl is one of the older but still indispensable varieties, a dainty pale pink, compact in growth and about 3ft. high. Professor V. D. Wielen is a very beautiful white variety, having immense drooping plumes of snowy blossoms, the plants in the rich moist soil of the bog garden reaching a height of 5ft. to 6ft. Salmon Queen, as the name suggests, has flowers of a light salmon pink shade, a pretty contrast with other sorts, and plumes 2½ft. high. Simplicifolia rosea is the result of crossing

ASTILBES ARE EMINENTLY SUITED FOR PLANTING UNDER TREES IN SHADY CORNERS OF THE GARDEN—



—AND ARE USEFUL FOR PLANTING IN BOLD CLUMPS IN THE HERBACEOUS BORDER.

Digitized by Google

Astilbe simplicifolia with A. Arendsii. It has elegant foliage and sprays of dainty pink blossoms, useful and attractive in the rock garden or along the front of the mixed flower borders.

Other varieties of particular merit include King Albert, one of the giants of the family, from 5ft. to 7ft. high, according to position, with strong dark red flower-stems topped to a length of 2ft. to 2½ft. with pyramidal plumes of creamy white flowers. Siegfried is a dainty shade of rose-pink with dense flower-heads 2½ft. to 3ft. high. Betsy cuperus has elegant drooping plumes of pale pink and white flowers 4ft. or more in height. Meta Immink is a beautiful soft pink shade of colour, the flowers on dense spreading plumes 3½ft. high.

Asked to name a selection of six varieties, my choice would be King Albert, Granat, Professor V. D. Wielen, Siegfried, Amethyst and Gunther.

Though now rather overshadowed by the many new varieties of astilbes, several of the herbaceous spiræas or meadowsweets are indispensable in the bog garden and waterside. The most distinct is Spiræa palmata, a dwarf plant 1½ft. to 2ft. high with carmine-rose plumes; var. alba, white, and var. elegans, pale pink. S. Aruncus is a tall goat's-beard 4ft. to 6ft. high with massive creamy white plumes in July, very effective by the waterside. Also worthy of note are the double-flowered dropwort, S. Filipendula flore pleno with creamy white flowers which are useful for cutting; and S. venusta var. magnifica, a plant often 5ft. high with rich pink blossoms in July and August.

The heights given must only be taken as approximate, so much depends on the soil and other conditions. On very rich, moist ground a variety may grow 2ft. or more taller than the same sort in the sunny mixed flower border of ordinary soil. A. O.

A PLAN FOR THE HERBACEOUS BORDER

Practical Points on Designing and Planting.

PARADOXICAL as it may appear, the modern herbaceous border does not consist of a collection of herbaceous plants. Used in a strictly botanical sense the adjective pertains to or is of the nature of, herbs, having a soft stem that dies to the root annually, but in present-day parlance a much wider interpretation is applied to the term which is usually accepted as a convenient and comprehensive name for a mixed border of flowers, whose occupants comprise a number of herbaceous plants augmented by hardy biennials, annuals and other subjects that testify to its democratic character. This development has been beneficial in its effect, for it has been the means of enriching the colour display during a longer period of bloom, thereby extending the sphere of usefulness of the so-called herbaceous border and raising it to a height of popularity never before experienced in the world of gardening.

One of the attractions of a mixed border of hardy plants is its adaptability to variations of environment. Small and large gardens alike are improved by its presence and success is attainable in the colder regions of the north of Scotland, as well as in the genial climate of the south of England, provided that care is exercised in the selection of the plants. To the amateur who is endowed with enterprise and initiative and a little spare cash, it possesses great possibilities in the methods of treatment, and although changes may be made from time to time and losses made good, its claim as an economical proposition appeals to all classes. When the gardener can say "that bit is all wrong and that clump must be taken up, for the flowers that clash there will make another part of the border a joy," a long stride has been taken in the education and training which form a wonderful post-graduate course in the school of horticulture.

Among the factors which contribute to the success of all herbaceous borders are the preparation of the soil, the arrangement of the plants, and the adoption of a colour scheme that has for its object a harmonising and pleasing effect throughout the season. While the situation must also be considered, it is of secondary importance, because the wide and varied ranges of genera contains plants that thrive under conditions that exist in most gardens. Some there are which revel in sunshine, others prefer shade, some like wet ground, others are very tolerant of drought. A medium loamy soil that has been deeply cultivated is suitable to the general requirements of the plants, but as they are intended to occupy the same position for several years, the ground should be enriched by the addition of organic manure, chopped turf, leaf-soil and wood ashes. Incorporate horse manure with heavy soil and cow manure with a light medium because the cow manure is more retentive of moisture. All preparatory work is better to be completed a few weeks before planting, and when digging to a minimum depth of 2ft. the surface may either be left flat or gently sloped from the back to the front. In small gardens the width of the border may range from 4ft. to 7ft., but even the latter measurement would be out of proportion in a large garden where the broad turf walk is flanked by a long stretch of ground. There the herbaceous border sometimes extends to a width of 12ft. That, however, may be regarded as exceptional, and suggests that in the making of a new border, the breadth should have some relation to the length. Six or seven feet is an ideal width for the average garden and less than 4ft. is not desirable, as vigorous growing subjects would not be seen to advantage in such a narrow strip.

Opinions differ regarding the period of planting. Much has been written on the advantages and disadvantages of autumn planting, but when all is said and done the question can only be determined by climatic considerations. In the warmer southern districts, autumn or early winter involves little or no risk, but in cold and exposed districts, spring planting is preferable. Certainly this rule holds good in Scotland, where, owing to the cold, wet weather, it is safe to postpone planting until March. Before beginning operations the ground should be plotted out and the habit of the plants and the colour of the flower studied. Avoid overcrowding. Give every occupant room to develop without overlapping its neighbour, and see that no tall plants are placed near the front to screen the dwarfer specimens in their rear.

A BORDER WHICH IS BOTH WELL SITUATED WITH REGARD TO THE HOUSE AND WELL PLANNED.

A stretch of grass between double herbaceous borders is always effective.

Then there is another point which affects the arrangement and the choice and allocation of the plants. One of the first things the gardener has to decide when considering alternative plans is the system of grouping. Are the subjects to be planted singly or in groups that will produce broad splashes of colour? Admittedly a little bit of colour provided by a single plant never makes the same impressive show as that obtained by grouping a number of plants of one kind and colour, but common sense dictates that masses of colour should be reserved for expansive areas and the collection in a comparatively small border confined to single representatives. All plants, however, do not require the same space, and it is possible to effect a compromise by planting liliums, gladiolus, geums, montbretias, pentstemons, salvias, aquilegias and the like in groups of

Digitized by Google

three, while single examples of the larger subjects—astilbe, phlox, iris, thalictrum, etc.—will suffice. In a large border the size of the clump should be regulated according to the space available, but with few exceptions, of which asters, erigerons, lupins, spiræas, certain forms of dahlias and papavers are typical. Three is recommended as the minimum number of plants in a group. Irregularity of size and shape should be the aim. Similar conditions apply to the dwarf collection forming an edging, but in arranging the number of each plant it is well to remember that several species increase rapidly, and after the first year are difficult to keep within their allotted space.

As some plants take a long time before their roots are firmly established in their new position in ordinary garden soil, amateurs are recommended to use a special compost, made up of the following constituents:—two parts turfy loam, one part leaf soil, one part decayed manure, supplemented by wood ashes, a few handfuls of sand and a 6in. potful of bone meal to a barrow load. Thoroughly mix these ingredients and place a layer of the mixture below and above the root system, then press it gently and fill up the remainder of the space with the soil that was taken out of the hole. This treatment means a little extra time and trouble, but is worth it.

The accompanying sketch represents a border 30ft. long and 7ft. in depth. It may, however, be adapted to suit larger or smaller areas without affecting the general arrangement or colour scheme. If a reduction of space is necessary the subjects at either end should be deleted, while the bed may be increased by the addition of other varieties or by augmenting the number of plants in individual groups, which would further emphasise the effect obtained by massed colouring. For instance, Salvia harbinger, Geum Mrs. Bradshaw, montbretias, the aquilegias and tritomas and the clump of Scabiosa caucasica would certainly be improved by enlargement, but the substitution of other occupants is not advised unless plants of similar colour and habit are available. The ground has been plotted on the basis of three plants to a group, except in the case of bushy examples, of which the peony, astilbe and Gypsophila paniculata are typical, and in these cases the allotted space will only accommodate one representative. On the other hand, it is not advisable to specify a fixed number of plants to form the various dwarfer groups in front, which are intended to be irregular in size and shape. Any arrangement should, however, give prominence to the end groups (Sedum spectabile and Heuchera sanguinea) and the central space occupied by Saxifraga purpurescens, and if narrower groupings are preferred, the surplus space may be occupied by clumps of Mrs. Sinkins pinks and catmint (Nepeta Mussini), or additional varieties of primula. The plants have been selected with the object of providing a succession of bloom from the flowering of the pyrethrum and aquilegia in early summer, until autumn, when the phloxes, artemisia and Michaelmas daisies are at their best. J. Y.

CLIMBERS for ARCHES, PERGOLAS and PILLARS

MODERN conditions associated with house-building and land charges prevent the gardener of to-day indulging freely in what we may call landscape gardening, but no one can deny that this is in great measure atoned for by the artistic use of arches, pergolas, pillars and similar erections adorned with flowering shrubs. These erections may be of wood, stone or iron; wood is undoubtedly best, but stone, in the hands of a man with an eye to beauty, is not far behind; iron is substantial and much more kindly to plants than most people think, while, when fully clothed in its flowering shrub, the stiffness which is its drawback almost entirely disappears.

Climbers may be planted in autumn—now—or in early spring; after a good winter, the autumn-planted stuff will prove best, but at times there is little advantage in hurrying things on. No matter when planting is completed, however, the site should be prepared at once. With due precautions concerning the safety of the erection, dig out a hole a yard square and 2ft. deep. See that drainage is efficient, for, remember, the shrub is to be there for a lifetime in all probability and a sweet, freely drained soil is an essential first step. Fill in a layer of stones and rubble, cover with turf or freshly-fallen leaves and then fill the hole in with a friable, rich compost. The basis of this compost must be a good loam, to which is added manure, but not excessively, sand or gritty matter, a little broken leaf-mould, a liberal dusting of old mortar or non-active lime, and a couple or three spadefuls of the charcoal ash refuse from a garden bonfire. Mix, fill in loosely if planting is not to be done just now and bank it up on top meanwhile. Get this done at once, a fortnight at the very least before planting, and let it settle. Purchase of a climber for the site should not be mere haphazard, send-off-a-postcard chance. Carefully think the matter over, study the blossom and its effect, consider the general appearance of the erection clothed in the climber. Order the plants from a good source, do not grudge a shilling or two to get "first quality," and see that the planting can be completed on arrival.

HONEYSUCKLE MAKES A MOST DECORATIVE CLIMBER FOR A GARDEN ARCH.

I should place roses first in my list of favourites. There are climbing tea, hybrid tea, hybrid musk, noisette, Wichuraiana, multiflora and other kinds to choice, and the following are a few of each in order:—Bouquet d'Or, Mme. Cochet, E. Hermanos, Niphetos, Gloire de Dijon and Mme. Butterfly; hybrid teas are more plentiful, including Chastity, Gruss an Teplitz, Climbing Ophelia and others; Moonlight, Wm. Allen Richardson, Lady Gay, Sander's White, Blush Rambler, Dorothy Perkins, Excelsa, Snowflake, Yvonne and Jersey Beauty; American Pillar, Goldfinch and Crimson Rambler; Climbing Caroline Testout, Mme. Melaine Soupert, Lady Hillingdon, Conrad Meyer, and many others. One may, indeed, please any taste in roses. The clematis is another popular shrub for such positions, and we may choose the rampant-growing montana, the sweet flammula or, the most common of all, Jackmanii; dozens of fine varieties could be named, but we merely mention a few like Gipsy Queen, Comtesse de Bouchard, Miss Bateman, Crimson King, Lawsoniana, Sensation, President, Kermesina, Lucie Lemoine and Fairy Queen. Leaving the above two extensive classes from which even the most fastidious buyer may find something he loves, we pass to mention equally common

Digitized by Google

climbers, where the choice is more restricted. Ceanothus is a beautiful shrub and one may have such fine kinds as Mauve Queen, Gloire de Versailles, Mme. Simon or Topaz. The winter sweet, chimonanthus, is notable because it bears its yellow blossom in mid-winter, but it requires a warm spot. Honeysuckles are fairly good, especially the Dutch varieties, and some of the newer Chinese kinds. Pyrus japonica is also very fine and well known; Choisya ternata will do well in mild districts; the jasmines may include the common, the winter, the new Chinese and Lemoine's Pink hybrid; the passion flowers are very tender subjects and so, too, we may class the wistaria and its varieties; Polygonum baldschuanicum is well known and a rampant grower. It produces masses of pure white flowers in long panicles. It will ramble over an arch or old tree stump. H.H.A.

CHINA AND POLYANTHA ROSES

Hints on the Selection of Varieties for Present Planting.

THE China roses are, undoubtedly, the most perpetual of all roses, and they generally begin to flower in early June and continue until frosts put an end to the activities of all plants. It should be stated that China roses are not subjects for gardens where the smoke of large towns is a trouble to the grower. China roses resent a smoky atmosphere, but in gardens in country places they are beautiful things and grow, flower, and thrive well. I have seen many beds of these roses in various parts of the country, and in every case they have been really splendid. They are, pre-eminently, bedding roses, but many of the fine old sorts are now difficult to procure from nurseries as they have gradually been discarded. This is really a pity, because where a profusion of flowers is required over a long period for a show in bedding, the Chinas will hold their own with the varieties in any other section. The advance in the improvement of the hybrid teas, however, caused the attention of growers to be focussed almost wholly upon the sorts in that section, and the fine Chinas were neglected.

Of the sorts which survive and are still offered by nurserymen, there are several which are worthy of attention, and these are now noted. Perhaps the best known is the old sort called Common Blush. The colour is a blush pink. Hermosa, sometimes Armosa, is very closely allied to Common Blush, and is practically similar in colour. There were several beds of this rose at Balmoral Castle for many years, and the plants made a brave show. Cramoisie Supérieure is, to those who know it, still a great favourite. It has flowers of a deep, rich crimson colour, produced in great abundance. Irene Watts is a very sweet variety with its wealth of delicate rose flowers which are shaded with a seductive tint of salmon. Mme. Eugene Resal is another rose coloured sort with long tapering buds flushed with orange. Queen Mab is an extremely pretty thing with its soft rosy-apricot blossoms shaded with vivid orange. Mrs. Bosanquet is a very pale flowered variety, the blooms being a pale flesh colour. Mlle. de la Valette is one of the most lovely of the Chinas. The colour is a golden yellow flushed with coppery red. Titania is a companion to the latter. Titania has gorgeous little orange and crimson blossoms. Comtesse du Cayla, another very old China, is notable for its striking flowers of red, toned with orange and vermilion. Queen Mab, soft rosy apricot flushed orange; and Laurette Messimy, a charming rose coloured thing shaded with yellow, are now the pick of the old Chinas.

There are several roses closely allied to the Chinas, but these are not dealt with here, as it is questionable if they are now required in gardens when we have the hybrid teas. The most of the hybrid Chinas are evidently bred from hybrid teas, and many of them, I have observed, are inclined to take mildew badly. That is one reason for leaving them alone. In so far as the Chinas are concerned, it is well to say that they are almost immune from diseases of all kinds. They are grand, floriferous bedders, but, as already stated, they resent smoke. There are, nevertheless, many gardens in country districts where these roses might be employed more largely than they are at present. They are thoroughly hardy. Some of the Chinas are very strong growers and on that account are valuable for making hedges.

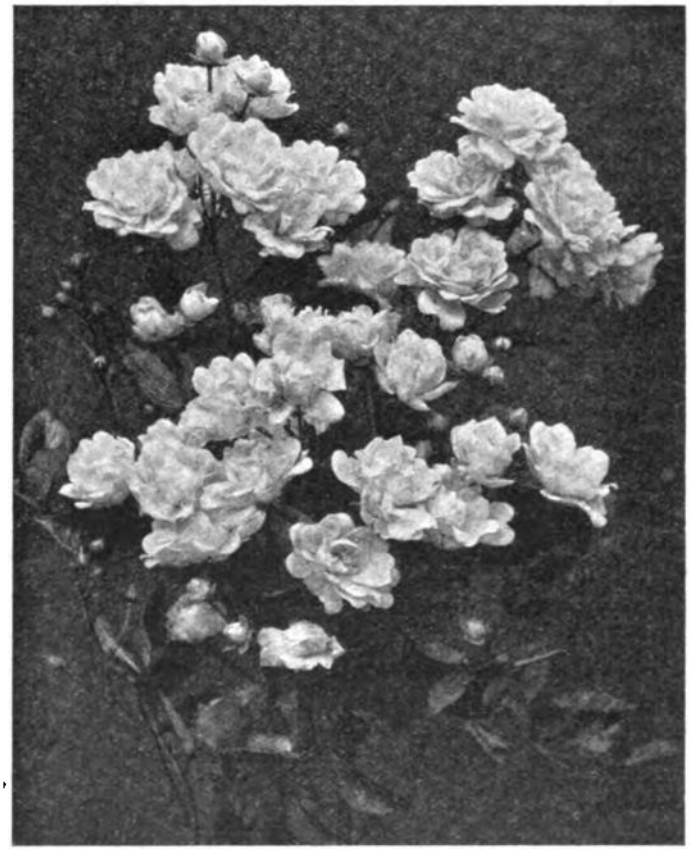
Rosarians are indebted the the late Rev. Joseph Pemberton for the re-introduction of the musks or musk hybrids, and practically all the best sorts sent out during recent years have been raised by him. I am convinced that the musk hybrids have a great future. In the average garden they can be used with great effect either for hedges or for planting in the middle of the beds as outstanding bushes. These stronger growing musks will, therefore, be dealt with when I write about roses for hedges.

One or two of the sorts recently raised are more of the bedding habit than the earlier sorts and these are mentioned now. Nur Mahal, sent out in 1924, although semi-double, is an attractive crimson rose. Penelope is another beautiful musk. Its flowers are a lovely shade of tender, shell pink, flushed with salmon. Aurora is a companion to Penelope. In Aurora we have a fine yellow rose of a wonderfully rich tone of colour.

The number of polyantha roses in commerce is now very large and they are introduced every year at an alarming rate, principally from France and Holland. Of the newcomers, however, few survive the trials they receive at the hands of the nurseryman. A marked change has come over the polyanthas during the last decade, and the original really dwarf type, like the old Gloire des Polyanthas, is practically lost. Originally of dwarf stature some of them are now as tall in habit as a vigorous hybrid tea. Else Poulsen may be quoted as an example. It is quite a good rose for the garden, and is, indeed, a wonderful flowerer, but it is too tall for association with other sorts. Raisers have got away from the standard and it appears to be no one's business to keep them to it. The N.R.S. may awaken to this fact some day.

There is a large number of polyantha sorts now in commerce that are simply sports from one of the older kinds, and the same sport, occurring in several places, will be found under another name in many lists. The trouble with these sports is that they are inclined to revert to the parent, and it is quite common to see, say, Orange King with one half of the plant with its typical orange flowers and the other half red.

Polyanthas are profuse bloomers, and are fine either for bedding where a display of dwarf growers is wanted or for making an edge to a bold rose border. The following kinds are recommended:—Eblouisante, a real gem with deep crimson flowers; Orleans Rose, cherry red with enormous trusses; Mme. Jules Gouchault, vermilion red; Yvonne Rabier, the best white; Coral Cluster, shell pink; Baby Tausendschon, pink shaded crimson; Orange King, bright orange pink; Mrs. Cutbush, deep clear pink; Perle d'Or, yellow and orange and an ideal polyantha; Erna Teschendorff and Edith Cavell, two good crimsons; Ellen Poulsen, bright rose; and Eugene Lamesch, orange yellow shaded rose. Leonie Lamesch, a very beautiful sort with coppery red flowers, is best grown by itself, as it will make a bush 3ft. or more in height. GEO. M. TAYLOR.



CORAL CLUSTER, A GOOD DWARF POLYANTHA FOR EDGING A ROSE BORDER.

THE BUSY MAN'S PAGE

November Reminders.

THIS month may be regarded as the first in the garden year.

The soil should be deeply dug, trenched or ridged up when the weather permits. Ground that is to be planted in the spring may be manured.

Young fruit trees and bushes of all kinds should be planted.

Established fruit trees may be pruned according to their special requirements.

Distinguish carefully between the fruit-buds and the leaf-buds. Also remember that fruits are borne on the young wood in the case of black currants, peaches, nectarines, morello cherries, etc., and on the older wood in red and white currants, sweet cherries, apples, pears, etc.

Cuttings of gooseberries and currants may be inserted.

Prune and clean old vines.

Finish the lifting of such roots as carrots and beet. Parsnips are better left in the ground to be pulled as required.

A sowing of broad beans may be risked this month.

Rhubarb, seakale, asparagus and chicory may be lifted for forcing.

Provide protecting material for sheltering celery, lettuces, cauliflowers, etc., if frost should suddenly set in.

All kinds of deciduous trees and shrubs may be planted now, also bulbs and spring-flowering plants, such as wallflowers, forget-me-nots, etc.

This is the best time of the year to plant roses with the possible exception of teas, which in cold localities may be held over until March.

Provide stakes for outdoor chrysanthemums which are coming into bloom.

Holly and privet hedges may be clipped.

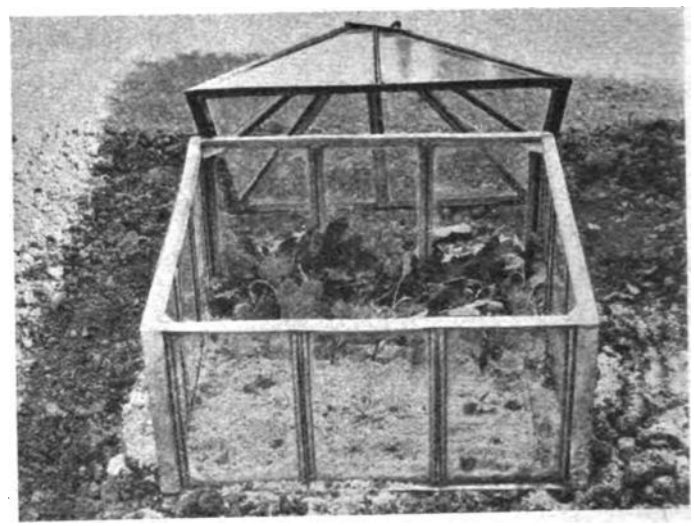
All climbing and wall plants should be carefully nailed or tied up, and old stems which no longer flower well and are bare near the ground may be cut out; but no other pruning should be done.

Complete the lifting of half-hardy bulbs and tubers, such as dahlias, gladioli, etc., and store in any frost-free and fairly dry place. The best way is to spread them out for a few days to dry after lifting, and then to cover with dry sand or earth.

Continue to give as much ventilation as possible in a glass-house or a frame. Only in foggy or very bitter weather should the structure be kept closed during the best hours of the day.

Arches, pergolas and other erections for climbing plants should be put up now, so as to give them time to settle before planting.

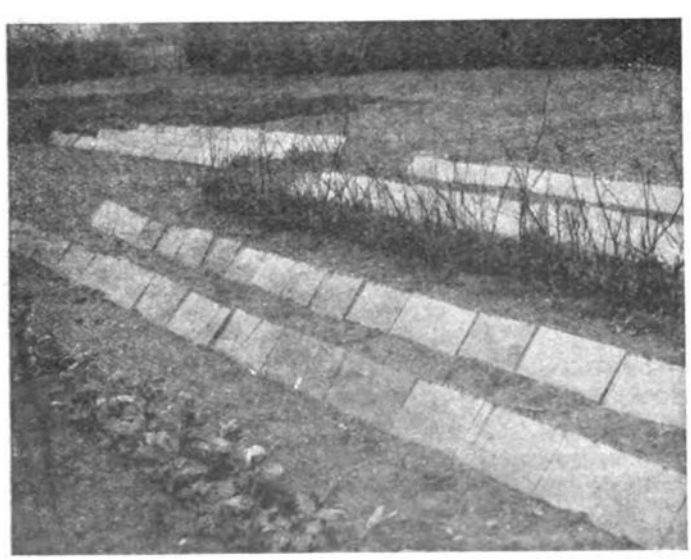
Leaves as they fall should be swept from paths and lawn and carefully stored for the making of leaf-mould or use in the formation of a hot-bed.



STRIKING CUTTINGS UNDER A HANDLIGHT.
These handlights can be used for many purposes.

Cloches for the Winter.

OUTSIDE the French gardens cloches are comparatively scarce, and yet they are very useful from mid-autumn until the advent of summer. What better method is there of guaranteeing a 100 per cent. rooting of cuttings of shrubs than by striking them under a cloche in the open? Larger sizes may be used to cover cauliflowers and continue the supply until late in the year. Lettuce may be grown on well into the spring under their care. Tender flowers are safe if covered by their kindly glass, and winter-flowering plants are beautiful when the cloche is employed to protect them. In spring seedlings may be safely raised in the open and plants grown on to maturity while yet they cannot be risked outside. Good crops of salads may be ensured with the cloche and some manure below it, and even in the greenhouse they can be used to cover individual plants and so make a greenhouse within a greenhouse. The older cloches are all more or less bell-shaped. The newer continuous cloche (Chase) is also very handy, particularly where rows of plants have to be covered or where seedlings are being raised. In essence they consist of a ridge of glass held together by wire, which can be laid neatly over the plants. Easy to handle, easy to store, and easily repaired when a part becomes broken, they have much to recommend them, and a few dozen soon repay the outlay necessary.



ROWS OF SEEDLINGS PROTECTED BY THE CHASE CLOCHE.
A handy and suitable cloche for protecting young plants.

Autumn Work in the Rock Garden.

IN order that the rockery may remain an attractive feature of the garden during winter and at the same time remain in fit condition for the plants therein, a sort of general overhaul is required this month. First of all structural alterations may be carried out; parts found to be wrongly designed, places which have given way in the stress of a wet summer and new additions may all be completed. After that has been seen to, take the garden shears and clip off all spent flowers. Not only does this lead to tidiness but it prevents seeds from becoming blown about where they are not wanted. At the same time there must be no hesitation in cutting back tufts which are inclined to trespass beyond their allotted area; this can be neatly done and the plants look tidy and under control. It is also a wise plan in many instances to lift dense tufts of foliage and dust underneath with lime or soot, or in bad cases with a soil fumigant, because various pests may find such places a happy home in which to pass the winter, and they must be discouraged. Choice alpines often resent stagnant water or continuously soaked soil round them. Remembering this, it may prove advantageous to take a handfork and loosen the soil in pockets which have been beaten hard in the recent spells of heavy rain. Chips of stone may also be wedged in the soil or placed round plants, not merely to promote the necessary drainage, but also to keep the plants in conditions they love, at least somewhat like the mountain side and moraine conditions. Many take the opportunity to mulch the pockets of soil at this time, but in some cases it is better to wait until spring before top dressing the rockery. A pile of loam is built up in the shed; to this is added well-rotted manure, teased out fine, and sifted leaf-mould. Coarse bone meal is also good when manure and mould are not too plentiful. Smaller heaps containing much lime in one instance serves for dwarf wallflowers, androsaces, arabis, etc., and, in the other, peat is employed almost alone for heaths and dwarf rhododendrons. This compost, filled into pails, is carried to the rockery and pressed firmly round plants. Clear away all drifts of fallen leaves; not only do these harbour various kinds of pests, but, when once thoroughly soaked, they never really become dry again and rot out the plants underneath. It may be necessary at other later dates to repeat this very important task, as fallen leaves are a danger among small plants. Overhead protection in the form of sheets of glass may be given to plants exposed to rain. Small pieces of mat will save many a plant apt to be ruined by strong sunshine after frost. Half-hardy roots ought to have a mulch of sand or fine ashes, and a handful of ferns may save something choice if applied in time.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Autumn Fruit Planting.

AUTUMN tints are showing. This should remind us that the planting time for trees and shrubs has arrived. Sap is moving, scars are being hurriedly sealed over with layers of cork, and root activity is being reduced. Autumn is the best planting season, and a spell of fine autumn weather works wonders with newly planted trees. What fruit to grow in the average home garden is a common problem. It is sometimes thought that acres of land are necessary for fruit culture, but this is not so. But in a small garden it is important to select suitable kinds of fruit.

If I were the owner of a small garden of five or seven rods, I should select the following: Twelve black currants of a good variety, like the Baldwin—this because black currants (fruit) are dear to buy and easy to grow—four loganberries, again easy to grow, and very useful for training over fences or sheds; four bush apples, two James Grieve for dessert and two Bramley's Seedling for cooking—these two flower at about the same time and would pollinate each other, thus ensuring a good crop; twenty-four raspberries, preferably Lloyd George, which is both a summer and autumn cropper; twelve gooseberries, six Whinham's Industry, red, and six Golden Drop. I should also grow one Morello cherry as a wall fruit. Plums and pears I should leave out, as both are uncertain croppers, especially in a small garden.

I do not suggest that fruit should monopolise all the garden, and, of course, there are many other excellent fruits which might be grown; but the amateur's difficulty is to know what to ignore.

For the larger garden the following are all reliable varieties:

Apples.—Dessert: Beauty of Bath, August (plant with others to ensure pollination); James Grieve, September-October; Cox's Orange Pippin, November-January (plant with others). *Cooking:* Grenadier, August-September; Rev. W. Wilks, October-November; Newton Wonder, December-May. These six apples should give a continuous supply of fruit from August to May.

Pears.—Jargonelle, August (this does well on a north wall); Williams' Bon Chretien, September; Louise Bonne of Jersey, October. Pears as a rule do not crop so well as apples, and this should be remembered when deciding what fruits to grow.

Plums.—Cooking or Dessert: Czar, early August; Victoria, September; Late Orange, October.

No time should be lost in ordering fruit trees. Order from a reliable firm and preferably one with a reputation to keep up.

Preparation for planting.

Preparation of the sites for fruit trees and bushes should be started at once. For trees, dig a hole a yard square. Thoroughly break up the sub-soil, and mix with it a few forkfuls of decayed manure, a couple of handfuls of bone-meal, and a spadeful of lime or mortar rubble. Leave the holes open to allow sun and air to weather the soil until the trees arrive. Examine the roots of the tree. Cut away bruised pieces with a sharp knife before planting. Use the soil mark as a guide for the depth to plant. Water if the soil is dry, and do not plant when the soil is either very wet or frosted. Prune the shoots half-back a couple of months later. Bush fruits are best planted in rows, using a line as a guide. Plant raspberries, currants and gooseberries 3ft. to 6ft. apart each way. Loganberries grow rapidly, and a strong plant will cover 20ft. of fencing in a season.

Treatment of Garden Steps.

IT is not difficult to produce an artistic setting for the few steps which often have to be constructed where one part of the garden is on a different level from the rest. Most gardeners can contrive to clothe the step-sides where these are in full sunshine, for such plants as arabis, cerastium and mossy saxifrages find a natural home in the crevices between stones or bricks. But in the garden shown here the steps are in a very shaded position. Two stone vases are planted with funkias, whose broad leaves are a constant joy all through the summer months. Ferns on the sloping banks at the side are quite at home in this position, and grow luxuriantly. A tree stump at the lawn edge has been thoughtfully allowed to remain, and been covered with ivy. Such an approach to the flower-bordered strip of grass adds greatly to the beauty of this small garden.

AN ARTISTIC SETTING FOR GARDEN STEPS. FUNKIAS WITH THEIR HANDSOME FOLIAGE OCCUPY THE TWO STONE VASES.

Plants to Treat with Respect.

NOT long ago I heard of an amateur gardener who had bought some peonies, planted them, watched them make their leaves during one season, and then had dug them up to see what was the matter with them because they had not flowered! He had not yet learned the lesson that flowers, like some human beings, cannot be hurried, but must be allowed to develop in their own way. Peonies resent disturbance. When once they begin to flower they should be watched, and not moved until they show signs of deterioration or overcrowding.

Another plant which likes to be left severely alone when the rest of the border is going through its triennial renovation is the Oriental poppy. The roots of this plant are fleshy and are very easily broken. In fact, it is almost impossible to lift one, even with a good ball of soil, without doing damage to the roots. The result is that even if flowers do appear the following season, they are poor in comparison with the flowers on plants that were left undisturbed. Madonna lilies and Christmas roses are also plants which like to remain unmolested for fully six years at a time. The latter may be lifted and divided now, if this is necessary, but it will probably not bloom for a couple of seasons after this treatment.

Multi-coloured Border Edges.

IN a moist situation, with a rich loam, such as they delight in, the St. Brigid anemones will thrive and increase from year to year. These delightful flowers with their extraordinary colour variations, make excellent edgings to borders in places where they are allowed to grow undisturbed. A shady situation, such as that beneath a light pergola, will suit them as well as a sunny one, and as the blooms make good cut flowers they are doubly useful. They are not altogether hardy, and a little protection from frost is beneficial during very cold spells. Leaves, ashes or dry litter would give sufficient protection.

On a north border, the scarlet windflower, Anemone fulgens, would do better than the St. Brigid anemones. They are more hardy, and will make a brave splash of colour in the sunless border. Both these fine anemone may be planted now, from 2ins. to 3ins. deep and from 3ins. to 4ins. apart. If they are to be planted on soil which does not retain moisture, a good layer of farmyard manure, or leaves placed a foot below the soil surface will help them. In any case, the subsoil must be well broken to ensure good drainage.

Preparing for Early Rhubarb.

DURING early spring, when fruit is scarce, only those who are fortunate enough to possess a store cupboard of bottled fruit can enjoy their own garden produce in their pies and tarts. Then it will be that we shall watch eagerly for the first few sticks of tender rhubarb. Now is the time to ensure that the rhubarb shall be early and up to quality. Clean up the beds, remove the dead leaves from the crowns, and give a good dressing of leaves and manure over the tops. This will keep them warm until growth commences, when cloches or other coverings can be put over the plants to force early growth.

THIS WEEK IN THE FLOWER GARDEN

An Evergreen Flowering Privet.

ALTHOUGH the privets are commonly grown for their foliage, there are a few species which form really attractive flowering shrubs. Probably the best of these is Ligustrum lucidum, which is worthy of a much wider cultivation than it secures. The shrub is evergreen, has dark shining leaves and forms a large bush, upright rather than spreading. In September the panicles of white flowers are produced on a generous scale just when flowering shrubs are scarce. L. lucidum is perfectly hardy and has proved itself to be a very good subject for the town garden. There are several varieties with variegated leaves, of which that known as aureo-variegatum is perhaps the best. On the whole the type is the most desirable, for it flowers much more freely than the other forms and its shining leaves are pleasing throughout the whole year. This privet succeeds best in a loamy soil, although it is very accommodating. To secure a vigorous growth it is important before planting to dig the soil deeply. Take special care to spread out the roots well and tread the soil down firmly. L. lucidum is not a difficult plant to propagate, and cuttings of well ripened wood may be taken in the autumn and winter and set in sandy soil. These may be placed out of doors, but much more certain results are secured if the cuttings are kept in rather a close frame for a time. When the cuttings have rooted pinch out the tops in order to encourage the development of a bush-like growth.—L. B.

IN THIS ATTRACTIVE FRONT GARDEN EXCELLENT USE HAS BEEN MADE OF FLAGSTONES FOR A PATH, AND ALSO AS A CLEAN EDGING TO THE BEDS AND THE LAWN.

Trees and Shrubs for Thin and Chalky Soils.

IN a general way trees and shrubs of nearly all kinds thrive best on a well worked loam. Thin soils, especially on chalk, are much more difficult to plant successfully. In such cases it is important to select subjects which have been proved to be suitable. In planting these it is well to break up a few inches of the chalk and place manure on it. Surface dressings of manure will be very helpful and these should be put on in the autumn every year. Here is a list of plants which will succeed in thin soil :

Trees.—Acers (maples), copper beech, mountain ash, Pyrus floribunda, almonds, peaches, cherries, thorns of all kinds, laburnums, catalpa, holly.

Shrubs.—Berberis, box, spiræa, brooms, kerria, mock orange, ribes, euonymus, St. John's wort, lilacs, viburnum, Magnolia conspicua, sumach, laurels, acuba.—L.

Flagstone Edges to a Lawn.

THE edges to a lawn are a problem to the busy amateur, and should the plants on the border encroach over the grass it is soon spoilt. The idea of using flagstone, as shown in the illustration, is an excellent one provided that the stones are not raised above the grass. Square pieces are used in this example, but odd-shaped stones will do equally well if they have one straight side to face the border.

A Dwarf Juniper for the Small Rock Garden.

Juniperus hibernica compressa.

A GOOD rock garden is incomplete without the presence of at least a few of the dwarf-habited shrubs and trees, forms of taller subjects. One of the most delightful of these is Juniperus hibernica compressa, the dwarf form of the Irish juniper. It has been long in cultivation, but no doubt its price has stood in the way of its acquisition by many amateurs of limited means. It still remains a choice subject, for which a charge of about five shillings is made : but it must be said that it is worth the money, especially when we consider that plants on their own roots take a good while to attain a saleable size. At most this juniper grows little more than an inch in a year, and it never attains a stature making it unsuited even for the small rock garden. It is exceedingly pleasing and attractive, with its small shapely columns of blue-green foliage, so shapely as to delight everyone. It is not difficult to grow in the rock garden, but I consider that it is liable to suffer somewhat from drought if in too dry a position. It is thoroughly hardy.—S. A.

Perennial Larkspurs to Plant Now.

THERE are several species of these stately plants, but it is with the garden hybrids and varieties that will be dealt with in this note. The wonderful creations of recent years are not to be compared with the larkspurs of thirty or forty years ago. The grand spikes smothered with flowers of perfect form and wonderful size are only one side of the flower's progress. It is in the magnificent shades of colour that we find cause for astonishment and admiration. There is represented every shade of rich purple and violet, every grade of blue from the very deepest to the palest of Cambridge blues ; then there is every mixture of mauves and lilacs. As a contrast to these rich-coloured kinds we have the wonderful range of varieties with white and creamy flowers.

Most soils, provided they are not too retentive, will grow them. It is important to dig deeply and to incorporate with the soil a generous supply of decayed manure. If the soil is heavy it may be rendered serviceable by the addition of leaf-soil, sand, wood ashes or any substance which will increase its porosity. In the case of a very light soil it may be improved by the addition of cow manure. Autumn is the best time to prepare heavy soils, but for soils of a lighter nature spring digging will do. Planting may be carried out in autumn or spring, but my long experience with these plants leads me to recommend spring planting. The plants must be well protected from slugs and snails by placing rings of soot and ashes round the plants, as these pests are very fond of the young growths. Old-established plants have a tendency to die off in the centre, therefore it is advisable to lift them every four or five years. The opportunity then occurs to divide the plants and increase the stock, and also to take cuttings if desired. Secure the latter with "heels" of the old growth attached, and insert in sandy beds under hand-lights. This operation, of course, takes place in spring. Delphiniums may also be raised from seed sown under glass in February or in spring in the open. In the latter case care must be taken to ward off slugs and snails, or the seedlings will soon be eaten off. Delphiniums should always occupy an open position.

There are now so many beautiful varieties that it is difficult to say which are the best. The following, however, will be found excellent : King of Delphiniums, indigo blue suffused plum blue ; Millicent Blackmore, blue and mauve ; Norah Ferguson, light blue flushed with mauve ; Rev. Edward Lascelles, rich violet blue ; The Alake, deep purple blue ; Lizzie van Veen, Cambridge blue ; Mrs. Townley Parker, sky blue ; Queen Mauve, pure mauve ; and, among the famous Wrexham strain, such varieties as Monarch of Wales or Joybells are most decorative.—F. M. H.

Diplacus glutinosus for a Sunny Wall.

THIS is a shrubby member of the musk or mimulus family, and, although well known as a greenhouse subject, it is not often met with outside. At Castleford, Chepstow, a plant has flourished at the base of a sunny, warm wall for several years. During frosty weather it receives the protection of a straw hurdle, and occasionally the growth is killed back to the old wood. In the spring, however, it makes rapid progress, and soon recovers

Digitized by Google

lost ground. Mild winters hardly affect it, and after such a season the plant is very showy, and covered with flowers the greater part of the summer. D. glutinosus is a native of California, and the colour of the flowers is a buff orange, while the varieties coccineus and Sunbeam are a richer shade. These two forms are not such a success outside, but in sunny situations both are particularly bright and effective. All are readily increased by cuttings, and good-sized specimens are often employed in the scheme of bedding, or mixed flower beds, so much in vogue in many districts. If grown as a greenhouse plant, it requires the same treatment as is meted out to fuchsias.—T. W. B.

Plants for the Shrubbery Front.

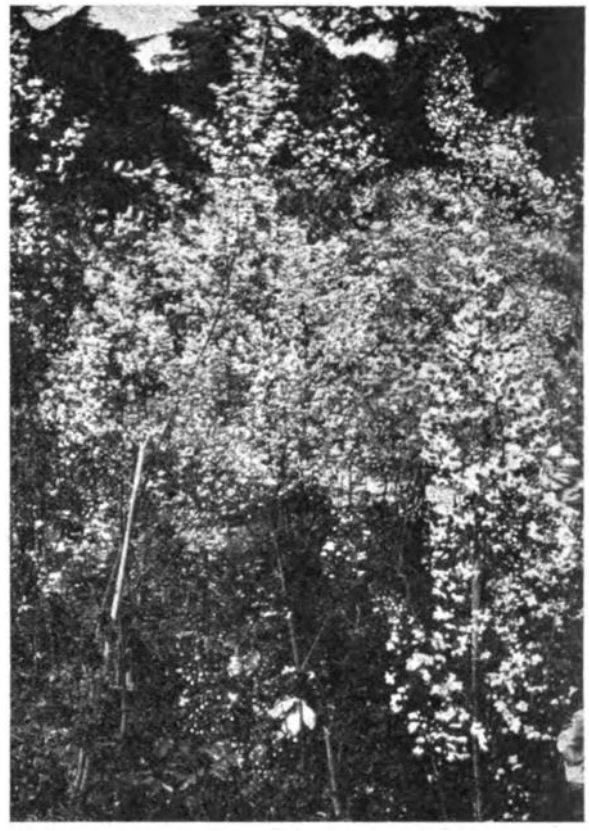
A PLEASING effect may be obtained by planting certain flowering plants among and in front of the foremost occupants of the shrubbery. In the case of newly planted shrubberies there will be vacant spaces for several seasons if due regard has been paid to the future development of the various subjects, while, where space is limited for the cultivation of border plants solely, certain kinds, being specially suitable for associating with shrubs, may be allowed to remain indefinitely. Established clumps of tritomas are responsible for brilliant flame-like splashes in many shrubberies, and flag irises are equally at home there. To get the best results these should be placed so that when in bloom they harmonise with the shrubs flowering at the same time in close contact with them. There are various lilies that may be used similarly, Lilium auratum being particularly attractive, while groups of tigrinum, pardalinum, elegans and chalcedonicum are very effective when in bloom. Tree lupins, too, may be regarded as permanent tenants of the shrubbery. Peonies, delphiniums, hollyhocks, Oriental poppies, Japanese anemones and rudbeckias may be introduced to fill empty spaces while the shrubs are developing. Discrimination must, however, be used when planting, otherwise it will be found necessary to remove many of the plants before they have had time to develop fully in consequence of the shrubs taking up more space than was contemplated when planting. The latter must not be unduly restricted for the benefit of their temporary associates. As an edging to the shrub border polyanthus are most effective and they flourish even in semi-shade.—C.

POLYANTHUS PRIMROSES MAKE AN ATTRACTIVE EDGING TO A SHRUB BORDER IF PLANTED CLOSELY.
Other subjects can be planted among the shrubby inmates.

An Attractive Meadow Rue for the Border.

Thalictrum dipterocarpum.

AMONG plants suitable for the herbaceous border this meadow rue can safely be placed in the first fifty, for it is indeed a most beautiful subject. It was introduced by Messrs. J. Veitch and Sons from western China, where it was found at elevations of 4,000ft. to 5,000ft., and there is no question about it being hardy in this country. It somewhat resembles T. Delavayi, especially in the pretty glaucous green, fern-like foliage; but the tall, graceful panicles exceed in height those of the species mentioned. The flowers are numerous, being a lavender mauve with prominent yellow stamens. When well grown this plant will reach 6ft. in height, but the average length when in flower is from 4ft. to 5ft. Much depends on the soil, and the best results are secured from a deep loam, although some recommend a more or less stony root-run. No one, however, need fear planting it in the average border, and it is worthy of being planted freely in the reserve garden for cutting purposes, its light and graceful spikes rendering it extremely attractive, both for the dwelling-house and exhibition purposes. Plants can be obtained at a reasonable figure, and a profitable method is to raise a batch from seeds. Last March a few seeds were sown which soon germinated in a cold frame, and in September the best of the plants were beginning to flower in the open ground. Naturally, they are only 2ft. high, but next year will show a considerable improvement. The normal flowering period is August for established plants, and they remain in full beauty for several weeks. Moreover, they set a good crop of seeds, and the word "dipterocarpum" refers to the flattened winged-like appearance of the ripe seed-pod. It is a perennial of the first water, and I have a few plants that have annually produced their spikes for the last eight years.—B.



THE BEST OF THE MEADOW RUES.
Thalictrum Dipterocarpum, an admirable plant for the herbaceous border.

Perennial Flax.

THE perennial flaxes (linum) are most useful for the front portion of any dry, sunny borders and they are sure to succeed even in the most ordinary garden soil. In a mixed border, groups of from six to a dozen are really very effective as the flowers, which are freely produced, present a variety of very gay colours. All these flaxes are easily propagated by the division of roots in the autumn or by seeds sown in the open border in the late spring. The best kinds for ordinary purposes are as follows. L. perenne, a very graceful plant which grows to the height of about 18ins. and produces quantities of pale blue flowers in June and July. There are white and rose coloured varieties of this form. L. flavum, with yellow flowers, grows about a foot high and will remain a mass of golden blossoms for a long while. L. narbonense has very fine blue flowers which are borne in great profusion. L. arboreum is shrubby in habit, although the plant does not grow more than about 18ins. in height. In a warm, sunny position, this species will become covered during the summer with yellow blooms.—L. B.

A Decorative Viburnum.

THE genus viburnum is composed of many different species, which vary greatly in appearance. Viburnum rhytidophyllum is, however, one of the most singular, on account of its handsome foliage. The evergreen leaves which are deeply channelled and grooved, are of a dark, shining green and often become as much as 8ins. in length and 2½ins. in width.

Large panicles of creamy white flowers develop at the extremities of the shoots and these are succeeded in the autumn by fiery red berries which persist well into the winter.

The plant succeeds well on a sunny wall; it may also be grown as a bush in a sheltered position. Little pruning is needed with the exception of the removal of sufficient shoots to keep it in shape. A light, well drained soil should also be provided, as it is detrimental to its well being for its roots to be in a water-logged soil in the winter.—G.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

"THE best laid schemes o' mice and men gang aft agley," and when the old saying is applicable to garden work it is generally the weather that is to blame. When writing about the lifting of dahlia tubers and gladioli corms one could hardly anticipate a three weeks spell of glorious weather in October, which, by prolonging the period of bloom beyond the normal season, upset all calculations and interrupted routine work in the garden. The change came on the morning of the 20th, when nine or ten degrees of frost were registered in exposed situations. A few favourite flowers that had contributed to the gaiety of the autumn display survived the ordeal, but succumbed when exposed to the low temperature on the following night. This sudden passing of the season's bloom naturally created mixed feelings in the heart of the gardener, for, although the combination of autumn tints and the rich colourings of the dahlias, roses, phlox and gladioli produced a charming picture that delighted the onlooker, there was the desire to overtake the arrears which had accumulated by reason of the mild weather. There is nothing now to prevent the amateur from undertaking the work of "redding up" his beds and borders and transferring his plants to a place of safety for the winter.

Altogether it has been a most remarkable season. Roses blooming freely so late in the year is by no means unusual, but it is surely a rare experience to see the noble spikes of gladioli clad in a floral garb in the third week of October. The primulinus hybrids have been prominent in that respect, and the art shades of salmon, pink, yellow and orange were probably appreciated and admired more than was the case in late summer. A few weeks ago an English raiser of roses paid tribute to the free-flowering qualities of the new dwarf hybrid polyantha Kirsten Poulsen in autumn, and here in Scotland it has maintained its good reputation until near the end of October. This beautiful seedling from Orleans deserves a place in every collection. It was first exhibited in 1926 by Messrs. James Fairley and Co., Cairneyhill, Fife, and its large trusses of vivid scarlet with golden anthers carried erect on stiff stems commanded unusual admiration. There is no other variety of polyantha to compare with it for brilliancy of colour, and, apart from its decorative value in the garden, the flowers keep well in the cut state. Some rosarians are rather prejudiced against the polyantha species generally, but if they could only see a bed of Kirsten Poulsen, or when grown as an edging to a rose border, they would probably modify their opinion.

While writing on the subject of roses, it may not be inappropriate to mention the beneficial effects of basic slag when applied at this season as a surface dressing. This by-product obtained in the manufacture of steel is a cheap phosphatic manure and, being slow of action, may be safely used at the rate of three or four ounces per square yard. The manurial efficiency of basic slag depends in great measure upon the fine quality of the powder, and next to the percentage of phosphates that is the most important consideration.

It is a common practice among amateurs who do not raise biennials from seed to delay the planting of wallflowers, sweet william and myosotis until spring. They justify this procedure on the ground that it minimises the risk of loss or injury sustained during severe weather in winter, but they overlook the effect of similar conditions in March before the plants are established in their flowering quarters. In any case, the bloom of late-planted biennials, whose season is associated with the months of April and May, is seldom so satisfactory as that produced by the seedlings that were transplanted in autumn. As all the members of that popular trio are presently on sale at local nurseries, they may still be planted either by themselves or in combination with bulbs. The cultivated forget-me-not makes a pretty edging to a bed of early tulips, daffodils or wallflowers, and its decorative usefulness is accentuated when employed as a carpeting in a spring bedding scheme. A great advance has been achieved in size and colour of sweet william, and when planted in clumps or as an edging to a mixed flower border the salmon pink and scarlet forms brighten the garden in early summer when the spring flowers are over.

Any spare time in November may be put to a profitable use by allotting an hour or two in the rapidly shortening day to such practical operations as the digging or trenching of heavy land that has a tendency to retain stagnant water. A clay soil is invariably wet and cold, two conditions that are resented by, and sometimes prove fatal to plant life. Some classes of vegetables may succeed in a medium of that kind, but flowers and fruit are never happy. Some writers advocate early spring digging as the most beneficial for plastic ground, but I consider that the advantage lies in late autumn or early winter tillage, which leaves the surface rough or in ridges. The broad principles which govern the management of farm land for the production of potatoes and other root crops are equally applicable to garden ground where vegetables are to be raised, so that the procedure to be adopted by amateurs during the coming weeks is to prepare the soil by deep digging and manuring. This method is also suitable for the cultivation of certain flowers, such as dahlias, sweet peas, peonies, iris, delphiniums and all herbaceous plants which benefit by the breaking up and porosity of the sub-soil. The garden ground attached to many of the housing schemes in Scotland consists of a clayey soil quite unsuitable for cultivation and presenting a discouraging problem to the tenant entering into occupation for the first time. The prospect of laying out a garden under such conditions is not inviting, especially to the novice who has never before attempted to grow flowers and vegetables. Two methods of treatment are available. He may decide on the easiest course which consists of simply digging over the ground, and thus postpone indefinitely the task of improvement; but if he is wise he will emulate the example of the owner of the Championship Garden at Glasgow and devote his spare time in the coming winter to trenching. It means a lot of hard work, but trenching is the only satisfactory solution, and it will be instrumental in preventing disappointment in future and prove in the end a real saving of labour. Fine weather in November also offers a convenient opportunity for carrying out any alterations or rearrangement of beds and borders which may be considered expedient. The plants are now in a dormant condition, and when lifted with a substantial ball of soil attached to the roots they may be accommodated on the surface of a vacant piece of ground until the new site is ready for their reception without much risk of injury. It is an occasion, too, that facilitates the work of dividing subjects which have exceeded the space allotted to them.

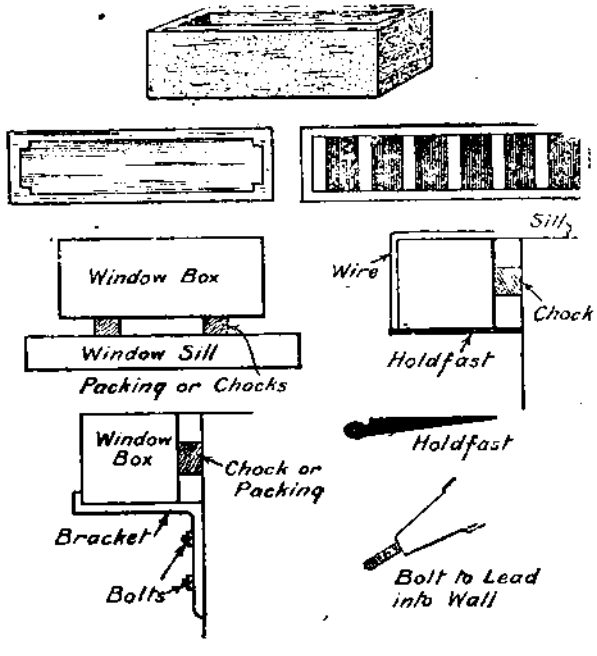
ST. MUNGO.

MAKING A WINDOW GARDEN

How to Overcome Difficulties.

Preparation.

THE possibilities of window gardening have been fully exploited during recent years and even in the meanest streets of our grimy cities one may often see these miniature gardens ablaze with colour during the summer months. Not infrequently window gardening is objected to on various grounds. It is said that window boxes attract undesirable visitors, such as insects, spiders and earwigs into the room! They are damp! They not only block the view, but make it a most difficult task keeping the bottom corners of the windows clean. With all these complaints I sympathise, and particularly where that old-fashioned "atrocity" the cork-covered window box is used. The crevices in virgin cork offer ideal retreats for all kinds of insect pests. It is also quite true that a box placed upon a window sill not only blocks the view, but it is not pleasant to look upon. However, there is no need for the window box to *be* on the *sill*, and surely virgin cork is not a necessary decorative adjunct. The ideal and hygienic way to get up a window box is against, or rather on the face of the window sill. A glance at the plan and elevation shows the ideal method of fixing. No water can run into the room, no blocking of view from the window, the fear of insects coming into the room is reduced and yet the full beauty and effect of the plants are retained. The back of the box bears "chocks" or packing pieces to keep the box from the wall. Holdfasts are driven into a "seam" in the brick or stonework to support the weight of box and from these irons a



Digitized by Google

strong wire is taken to a screw eye (iron ring) made fast to window framing. A more professional way of carrying out this idea is as follows. Have some iron brackets made of a suitable size and strength to bear the weight of the window boxes. Now have some bolts made as shown in sketch. The bolts are made to "lead" into the wall. A hole is made (drilled) with an iron chisel and the bolt let in until the screwed or threaded part protrudes half an inch plus the thickness of the bracket. The brackets are bored and slip on to the bolts, the nuts are tightened and a firm bracket on which a good heavy window box may rest results. The advantage of this method of fixing is—that should one desire to remove the window boxes for a season (*i.e.*, winter), the nuts are simply unscrewed and afterwards put in place again, leaving no unsightly iron projecting. If the amateur feels himself incapable of doing this work, a local carpenter will do it at small cost. The bolts are made fast by leading—that is running hot lead into the hole. Window boxes may be made almost any size, but should be made of *red* deal, in fact, the gardener will be well advised to insist that all frames, greenhouse woodwork, etc., are made of red and not white deal, as the former is much better for outside work. The decoration of the outside of the window box is a matter of personal taste. The neatest window box is quite plain, painted stone colour, and sand dashed upon it while wet gives a stone-like appearance to it. There is no reason why the box should not be moulded. Black or dark green and white tiles look fairly well. The smartest ornamental window box, however, is one covered with beaten metalwork. The metal need only be sheet tin, not too thick. The box made, cut enough metal to cover it, then lay this down upon a piece of old carpet on a firm table and with a punch proceed to hammer. If desired some design may be worked out. Copper, of course, may be used in place of tin, but tin when treated with *very* thin black japan looks quite well. The mode of doing this is to warm the metal over a gas ring and apply the *thin* black japan. The tin must not be made too hot and if the work is carefully done a pleasing bronze effect will result. When ready fix the metal in position with fine brass shoe nails and a decorated box of a novel kind is yours. The box should *not* be painted inside with tar preservative. Use good paint to which a small amount of paraffin has been added—this keeps away pests. Having taken so much space in describing how to prepare and fix the window boxes, there is little left for the all important part of furnishing them. However, one cannot go far wrong; annuals, half-hardy annuals, pot plants of all kinds. Good soil is needed, but not too rich, and drainage must be made. A very popular plan is to keep the plants in pots, the pots being plunged into moss, fibre or sand. These and other matters relative to the subject will doubtless be dealt with in these pages later. Needless to say, all the fixing must be made secure and those who are doubtful of their ability to do the work properly themselves should call in a practical man. T. H. H.

WHAT OUR READERS SAY

PRIMULA RUSBYI AND P. ELLISIÆ.

SIR,—In my illustrated article on hardy American Primulas, published in THE GARDEN on August 1st, 1914, I stated that I could not grow P. Rusbyi in the open. Since then I have changed my opinion, as I have it doing well in a shaded rose border.

P. Ellisiæ is a plant also from the Rockies, and resembles P. Rusbyi in many ways, but it is a larger and stronger grower and much more hardy. With me it does well in the open border shaded from the direct rays of the sun. It flowers fully a month earlier than P. Rusbyi, but the flowers are not such a good colour, being a duller shade of deep lilac as compared with the crimson purple of P. Rusbyi. As will be seen from the illustration the leaves, instead of being erect, as in P. Rusbyi, have a distinct tendency to roll backwards. They are also of a lighter shade of green and of softer texture. I had both species on my stand at the Chelsea Show last May, and pointed out the differences to several people who were interested in primulas.—JOHN MACWATT, *Morelands, Duns*.

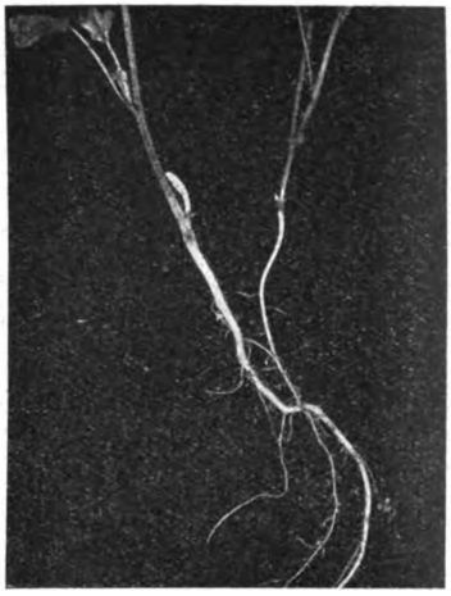
PRIMULA ELLISIÆ, SIMILAR TO P. RUSBYI, BUT IS OF MORE ROBUST HABIT AND FLOWERS EARLIER.

"WANTED NAME OF AN OLD SINGLE CHRYSANTHEMUM."

SIR,—Seeing the letter from Mr. G. A. Russell, Radlett, and your reply to same, it may help him to know that many years ago I sent plants of single chrysanthemums to a friend of mine at Wallington, Surrey, and one of them answers to his description. It was called Bronze Pagran. There is also another very old beautiful single, called Edith Pagran, and also I consider that there is no yellow single to beat the old Altrincham Yellow. These varieties I have never seen in the catalogues, but probably some firms may be able to procure them if ordered.—A. W. W., *Colwyn Bay*.

NATURAL ROOT GRAFTING.

SIR,—The enclosed photograph shows a remarkable case of what may be natural root-grafting which has taken place between two plants of lucerne (Medicago Sativa L.). The plants were two of many thousands dug up from some plots sown two months ago at Upper Slaughter, Gloucestershire. Part only of the leaf system is shown; both plants are of a healthy dark green.



A NATURAL ROOT GRAFT.

The "graft" has occurred 2ins. below the crown; the root of the thinner stemmed plant has pushed through the middle of the thicker root; the latter is also of a quite healthy appearance, though in the illustration a slight blackening, due to the lighting effects, shows at the juncture. Since attempts to pull out the ingrafted root were unavailing, there is probably organic connection between the two; this will be verified or otherwise when sections of the junction have been examined.—P. H. H. GRAY, *Rothamsted, Harpenden*.

[Cases of natural root grafting are not uncommon and those interested should keep a look-out for the phenomenon.—ED.]

A FEW GOOD AUTUMN FLOWERS.

SIR,—At the time of writing, as one looks around the garden one notes with sadness the increasing scarcity of flowers. Yet still there might even now be a few if people would choose to grow such as I shall now mention. First and foremost in my mind are pentstemons (Southgate Gem). I have this still in full bloom in my garden, and it has been in this state all through the summer. Its brightest of scarlet flowers are most cheering, and I know even the first frost or two will not do much damage to it. It is quite easily struck from cuttings taken in September or even as late as this month. Inserted in sand in a cold frame they will stand the winter well, and if kept well pinched will make fine bushy plants by next spring. Of perennials we have, of course, the Michaelmas daisies, of which there are some grand varieties in Barr's Pink, Beauty of Colwall, Sam Banham (the best white), Pink Perfection, Climax and King George. Of annuals I would praise verbenas, cosmos, and antirrhinums. The great secret of encouraging the second crop of blooms lies in keeping old dead flowers cut off. When this is done regularly shoots are soon thrown up from axils of leaves forming the late flowers.

In the rockery I would recommend the rock roses, still flowering here. I have Jubilee (double yellow), Fireball (double red), and next month hope for the usual display of Iris stylosa, which provides my Christmas decorations.—W.

NURSERIES OF THE BRITISH ISLES.—X

MESSRS. AUSTIN AND McASLAN OF GLASGOW.

LIKE all other industries, horticulture has had many viccissitudes in its process of development all over the country. Many nurseries have sprung up at different times in past years only to die out during periods of depression in gardening, and it is always interesting now to come across a link with past history when we are so much concerned in recent comparisons of post and pre-war horticulture. It is agreed that interest in gardening has never been so great as it is to-day, but the fact that this self-same interest can be found away back 200 years ago should not be lost sight of. There were a number of keen enthusiasts who may be regarded as the pioneers of the modern nursery trade who did a great deal towards the development of horticulture and gardening in the eighteenth and nineteenth centuries, and among them is the firm of Austin and McAslan of Mitchell Street, Glasgow. Scotland has always been proud of her place in the world of gardening, and rightly so. She has produced gardeners and nurserymen whose names are well known in horticultural history, and it seems fitting that recognition should be paid to one of her long-established nurseries. Indeed, Messrs. Austin and McAslan are probably one of the oldest nursery and seed firms in the country which are still trading under their original name. They have had an interesting and varied history, and a brief account of their activities in their early years may not be without interest.

The business was founded in 1717 by John McAslan, who rented a piece of ground in what is now the central part of Glasgow. Along with the nursery a small seed shop in The Trongate was opened, whose activities can be traced from advertisements appearing in local papers about the date 1760. This shop was rented on a nineteen years' lease, and it is interesting to note the rent, which was £12 per annum. In the year 1782 Robert Austin, who was a foreman in the nursery, was taken into partnership, and the business was then styled McAslan and Austin. Mr. Austin served for a time in the nursery of Mr. Grimmond at Chelsea, and also at Hunt's nursery at Putney and Mr. Chamier at Epsom, and returned to Glasgow in 1779 to join the firm. He took an active part in the public affairs of the city and, among other things, was elected a corresponding member of the Royal Horticultural Society of London in 1817. Various changes took place in the site of the nursery about this time, necessitated by the extension of the city, and in 1798 it was removed to Little Govan, later in 1828 to Coplawhill and in 1868 to Titwood, where it remained until 1886, when further removal became necessary, to its present site in Cathcart. In 1803 the title of the firm was changed to the present one of Austin and McAslan, and a number of changes occurred in the control of the business. The shop was retained, but was removed to Buchanan Street, where it remained until the premises were burned down in 1888; new premises were then found at 89, Mitchell Street, the present headquarters. From 1850 until the present time many changes took place in the constitution of the firm, until now the three partners in the firm are Mr. James McMichael, Mr. John Cairns, who was for many years general manager, and Mr. H. S. Paton, who joined the business in 1924. From 1850 until 1880 the business was greatly extended and developed, and in recent years the extension has been marked until the firm is now one of the largest in Scotland.

In the early years it appears from the old records and letters which exist that a great interest was taken in shrubs and roses. Quite extensive collections were built up, and manuscript lists were sent out by the firm offering their stock for sale. Mr. Austin was particularly interested in the growing of the Double Scotch roses, and about the year 1816 a collection of some 208 varieties had been made, all grown on from seed in the nursery. That he was very proud of his collection is revealed in old correspondence to Mr. Wm. Aiton, the then Curator of Kew Gardens, and to various members of the Royal Horticultural Society of London, who were growing

several of these in gardens in the south. In 1817 a catalogue of these roses was issued in manuscript form, and since it may be of interest to many readers, and especially to keen rose growers, we give this catalogue in full, since it indicates the interest that was taken in the rose over one hundred years ago, not only by the growers but by gardeners who were keen to add any new varieties to their collection. As far as we know, none of the varieties listed in this catalogue is in cultivation in this country now, but if any of our readers have plants we should be pleased to hear from them, as many of the varieties listed according to their descriptions are well worth reintroducing to our gardens. This old rose catalogue must have been one of the first to be put out by any firm, and it is interesting on that account, since it shows the kind of rose culture at that time.

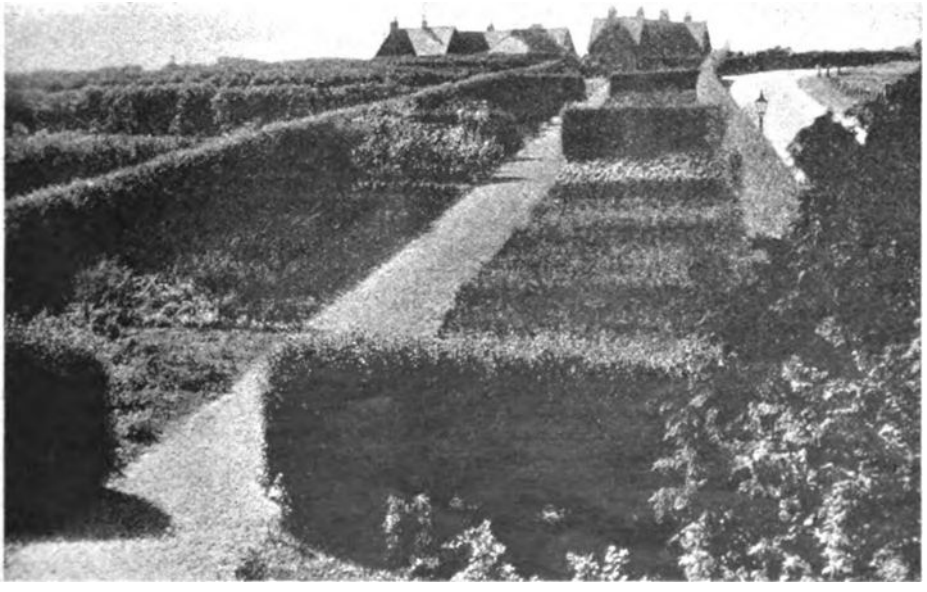
Coming to our own day, the firm occupies a prominent niche in horticultural circles, not only in Scotland, but elsewhere. The west of Scotland is the home of many fine gardens largely on account of its favourable climatic conditions, and Messrs. Austin and McAslan have done much to extend and develop the love of gardening in the wide area surrounding their headquarters. It is a firm with considerable initiative and enterprise. The business has moved with the times, and while formerly the connection was mainly with the larger Scottish gardens, it now has been widened to assist and cater for the large army of amateurs who are engaged in gardening as a pleasant hobby. That the directors of the firm realise the importance of the amateur gardener is evidenced by their desire to help and stimulate them to further effort. To that end the firm in 1926 instituted a spring flower show on their own account, and the widespread interest it created in horticultural circles, not only among amateurs but also professionals, has more than warranted the continuance of their enterprise. In other ways also they offer help to the amateur by conducting various trials in their nurseries and inviting all amateurs who are interested to see the results. This idea of co-operation between the nurseryman and the amateur is one that deserves to be fostered, as it will do more to promote a love of flowers and gardens among the vast majority than anything else. The nurseryman should be ever ready to help and assist the amateur with his difficulties and also to improve his knowledge of horticulture. Messrs. Austin and McAslan do both. This year the firm undertook a comprehensive trial of sweet peas, which has already been referred to in our pages, and the results were open to the inspection of anyone interested.

A BREAK OF MAIDEN ROSES OF ALL VARIETIES IN THE NURSERIES.

The firm's nursery at Cathcart, situated about five miles from the centre of the city, is well worth a visit during the summer months. They occupy between forty and fifty acres, and contain a wealth of garden plants. For many years a great interest was taken in the growing of fruit trees, since the supply of such formed an integral part of their business, and this still forms an important part, although it is now only regarded as a branch of the tree and shrub department. During the last four years, under the able charge of Mr. H. S. Paton, the nursery has been extended and the stock greatly increased, until now an admirable collection is to be seen. The shrub border in the nursery, set out for the advantage of visitors, houses representatives of almost every first-class garden shrub. Special attention has been given to those suitable for culture in amateurs' gardens, such as berberis, cotoneaster, philadelphus, deutzia, escallonias, spiræas, etc., while many ornamental conifers suitable for choice positions in the rock garden or the lawn or for hedge purposes are also grown. A number of less hardy shrubs which are commonly found in gardens on the west coast of Scotland, such as Desfontainea spinosa, metrosideros, berberidopsis, etc., are all to be found flourishing outside in the shelter of a hedge. All the shrubs, including the conifers, seem to take kindly to the conditions so near the town, which is testimony to the good nursery cultivation. The forest trees were a picture of health on our visit. Japanese larch, Scots pine, Corsican and Austrian pine, Norway and Sitka spruce are the principal trees grown. The high standard of quality of not only the trees and shrubs but of all the plants in the nursery was most marked. The plants are grown in blocks, each one roughly a quarter of an acre in extent, and each is separated by thick shelter hedges to break the wind. In addition to acting as a protection against the wind, the hedges serve to regulate work in the nursery.

One part of the nursery is given over to fruit trees. Apples were in good health and all the leading varieties are grown. In Scotland the kind of tree which proves most successful is the half-standard feathered type, and the rows of young trees in the nursery were excellent both in habit and quality.

The firm carries out every year a series of trials of vegetables, and at the time of our visit we were particularly interested in the lettuces which were in fine condition. Special attention is given to the selection of varieties of fine quality, and which stand well before running to seed. Vegetable production has always been kept in the forefront of the firm's activities, and the awards which amateurs have gained at Scottish shows from this firm's seeds testify as to their high quality.



THE DOUBLE ORNAMENTAL SHRUB BORDER WHERE A WIDE SELECTION OF SHRUBS AND TREES IS ON VIEW.

Digitized by Google

A choice and representative collection of alpine plants is also grown. The selection is wide and up to date. Many primulas are grown, including all those species that will become favourites in our gardens once they become better known, such as P. japonica, Bulleyana, pulverulenta, sikkimensis, Florindæ, mooreana, Red Hugh, etc. Gentians are also to be found in profusion, with G. sino-ornata and Farreri doing particularly well. The culture of the alpine plants is carried out with considerable skill, and the plants are robust and healthy, so that they will readily accommodate themselves to the varying conditions in the different gardens where they will ultimately find a home.

Messrs. Austin and McAslan also specialise in roses, and visitors to the nurseries will find much to interest them by a tour of the rose beds. Large breaks of roses form a decorative feature of the nursery, as from 10,000 to 15,000 bushes are planted in each break. In addition to the many varieties of bush roses that are grown there are rows of very fine standards. All the best and modern varieties are to be seen, including many of this year's novelties, and their worth as decorative varieties for Scottish gardens can be appraised first hand. The varieties are conveniently grouped so that one may be readily compared with another, and the good and bad points seen at a glance. At the time of our visit we were much struck with the excellence of Shot Silk and Ivy May, two roses that have stood up well to this inhospitable summer. Both show that they are first-rate varieties for amateur gardens in Scotland and also in the south.

Gladioli, another speciality of the firm, at the time of our visit, were at their best. The majority of the early and mid-flowering sorts were in flower, and the display of colour was most striking. Despite the lack of sun and the continual rain this summer, the plants were looking in good condition with spikes of extraordinary size and vigour both in the large-flowered and primulinus sections. As with roses, a very wide range of varieties is grown so that the best may be selected for recommendation to Scottish gardeners. The majority of our Scottish readers will have already seen what the firm can do in the way of gladiolus culture by the fine groups that have been staged at the autumn shows this year that gained for them numerous high awards.

The firm has various other activities too numerous to deal with in this short space. Suffice it to say that they keep quality in the forefront of their policy throughout the year, and that whenever possible they do their best to assist and co-operate with the amateur gardener in his gardening problems.

FRUIT AND KITCHEN GARDEN

This Month in the Fruit Garden.

PLANTING.—The planting of fruit trees and bushes may be continued this month. Remember to plant when the weather is fine and give the roots of the newly planted trees every opportunity of starting well; dig the holes large enough and work in some fine soil among the roots. Plant firmly and stake where necessary. Trees that are to be transplanted may be lifted and replanted now. Trim the roots, remove any tap roots and make your cut on the under surface of the root.

Pruning.—Finish the cutting out of old raspberry canes if that was not done last month and continue the pruning of gooseberries and currants. Take cuttings of your prunings if you desire to increase your stock. Remember to take your cuttings from healthy trees.

Cultivation.—Dig in between fruit trees in suitable weather and apply artificial manures, such as basic slag, etc., at the time of digging.

Pests.—Old pupæ of the raspberry beetle will be found in old canes. Therefore collect up and burn the prunings.

The eggs of the lackey moth may be found in bands round apple and pear twigs. Remove these and destroy them.

Autumn Cultivation in the Fruit Garden.

AFTER the leaves have fallen in the autumn it is good practice to cultivate between the trees or bushes. A spade should never be used among fruit trees except for the purpose of lifting or root pruning the trees. For cultivation between the trees use a fork. The cultivation necessary is merely the breaking up of the surface so that the air may get into it, and the plantation broken up after the treading that has been done in picking the fruit. There are a few points to be borne in mind in autumn cultivation. First of all, choose a fine day for the operation, especially if the soil is at all heavy, otherwise puddling may result and the last stage will be worse than the first. Secondly, avoid injury to the roots of the trees, *i.e.*, dig shallowly and use a fork. Thirdly, fork in the leaves, but be sure to bury them, otherwise it is best to sweep them up and burn them, as they harbour certain insects and fungus pests. Any manures which are to be applied, such as bone meal, basic slag, rock phosphate or other slow-acting manure, may be applied at this time. Horse manure may either be scattered on top as a mulch after forking over or turned in when forking over. The former is preferable where severe frosts are likely to occur, as it acts as a protection to the roots and may be turned in during the early months of the year.—H.

When Planting Currants and Gooseberries.

ALMOST everyone fortunate enough to have sufficient space at his command, likes to have a few bushes of these popular small fruits in the garden, so that a few words on this subject will not be out of place at the present time and should prove especially helpful to those who contemplate planting bushes this season.

In the first place, let it be said that the earlier this operation can be performed after the leaves have fallen, the better it is for the future of the plants, because early planting means that new rootlets will push forth and take a hold on the soil before the advent of severe weather and, consequently, the bushes start their normal growth in the spring, without any appreciable check.

When purchasing fruit-bushes always deal with a firm of repute, for "cheap" stock obtained through auction rooms or from foreign firms of doubtful reputation invariably turns out dearest in the long run. Very frequently it is weakly, diseased or wrongly named. If it is possible to view the bushes prior to purchase, so much the better, and the buyer should make sure that the bushes are free from diseases and pests, such as big bud, reversion, or American gooseberry mildew.

The preparation of the ground is very important. Gooseberries and black currants thrive best in a good retentive loam, rather moist and cool, although the former will do well on almost any ordinary garden soil, providing the position is open and sunny. Red and white currants do not require such a strong rooting medium and succeed admirably on any ordinary soil, well manured and not wanting in lime; they are excellent subjects for north borders or walls, in this latter case trained as cordons. In all cases the ground should be trenched or bastard-trenched and enriched by the addition of well rotted manure, and allowed to settle for some few days prior to planting.

The condition of the ground at the time of planting is also an important factor in the success of the operation. It should be in a crumbly, friable state. Planting in wet, sticky soil is exceedingly bad practice. Far better lay the bushes closely together in a trench and cover the roots with soil until better planting conditions obtain. On the arrival of the bushes from the nursery they should be carefully examined and any damaged roots or branches neatly trimmed away with a sharp knife.

The correct distance apart for planting bushes is 5ft. each way, and with currants, under suitable conditions, an additional foot will prove both desirable and advantageous. Take care that the holes are made sufficiently large to admit of the roots being well spread out without any suspicion of "cramping." Plant the same depth as the plants have been in the nursery—this is ascertainable by noting the position of the soil mark on the stem, and tread the ground firm, but not hard, as the work of filling in the holes proceeds. Pruning is best delayed until the spring, but it is advisable to remove and burn the soft tips of the gooseberry shoots, for if any American gooseberry mildew is present, it will be located in that portion of the plant at the present season.—T. H. E.

Root Pruning Fruit Trees.

WHERE a fruit tree produces poor crops or shows an excessively sappy growth, very beneficial results often arise from root pruning. It is a good thing to undertake this business while the weather is still open, as is usually the case in November. The process starts with the making of a trench 2ft. or 3ft. deep all round the tree. The actual position of the trench should be about a foot beyond the outermost branches. Cut back all the thick roots which are generally travelling some distance away from the tree, taking care to leave all the fibrous feeding roots. After the roots are cut dress the wounds with tar. For the cutting use a knife, or, in the case of very thick roots, a saw may be required. Some judgment must be used as to the extent to which the root pruning is carried. Trees that are growing very luxuriantly and bearing little or no fruit require the removal of a greater number of roots than those that are only moderately luxuriant. With large trees it is usually advisable, the first season, to make the trench half-way round and cut the roots on that side, leaving the other side until the following year. After the pruning fill in the trench with a compost formed of fibrous loam and well rotted manure. Tread well down and if the soil is dry give it a good soaking of water.

Planting Peaches and Nectarines.

CAREFUL preliminary preparation is a powerful factor in the future success of these fruit trees, and no efforts should be spared at planting time. First of all dig out the soil to a depth of 2ft. or rather more. If drainage is not good, lead a field drain along the bottom and, whether that is placed in position or not, fill in a 6in. layer of rubble, clinkers or stones. Cover this over with a 3in. layer of turf or leaf-mould. This being done, prepare a compost of good loam, preferably turfy loam, coarsely chopped up. To every barrowload add half

Digitized by Google

a stone of old mortar or a quarter stone broken shell, ground carbonate of lime or well slaked lime. Mix this with the soil and then add a liberal sprinkling of bonfire refuse containing much charred wood. Sand may also be needed, but grit or burnt earth will serve, its purpose being to keep the soil from "binding" and to promote porosity. Fill the soil compost into the hole and tread it firmly down to such a depth that just sufficient room is left to allow each tree to be planted at the same depth as in the nursery. Plant firmly and finally mulch some light littery stuff over all. The prepared border should be at least a foot beyond the spread of the roots. Next winter another foot may be prepared beyond this, and so on for a time, new rich soil being available for the roots as they extend. Always plant in dry weather and keep the prepared compost until it is required for the work under cover.—L.

Put Your Herb Borders in Order Now.

HERBS for storing should be cut, dried naturally and stored when they are in flower, then they will be harvested when at their full strength. But many cultivators have neglected to store the bunches. It is not too late, however, to cut, bunch and store some kinds now. Very little drying will be necessary. When the herbs are being bunched tie a small piece of clean paper to the stems so that, when the bunches are suspended, the flaps of paper will collect dust, thus preventing it lodging among the stems and leaves. Lightly fork up the soil between the rows of plants, clear away any weeds, put on a light mulch of rotted manure and cover the latter with about 1in. of ordinary soil.—HANTS.

Lifting Salsify.

THE present is a suitable time for lifting salsify and storing the roots. The latter should be carefully graded, the best-shaped ones being stored for the kitchen department and the ill-shaped ones for forcing during the winter months. The large, well shaped roots should be stored in sand in a cool, dry shed; the heap may be ridge, conical or flat-shaped. If flat, then the roots should be arranged in an upright position, placed as close together as possible, and quite dry sand be sifted over them until all spaces are filled right up to and just over the crowns. The smaller roots and those that are forked should be stored with as much care, then they will respond to treatment when forced for use as a salad.—CHRISTCHURCH.

Club Root or Finger and Toe.

CLUB root is a disease which may attack all members of the Crucifer Order, including cabbages, wallflowers, turnips and the like; it does not attack any other garden plant like the potato or the onion. The disease lives in the soil. It loves a wet, sour soil and, in a year like this, it appears with destructive virulence in many parts where it was not noticed before. Infested crops seldom come to maturity and, as they are centres of disease, they must be burned or buried deeply. After that has been done order 1lb. of quick lime for every square yard of infested ground, place it in a heap on the vacant land, scatter about an equal bulk of water over it gently, and leave it to slake and crumble overnight. Scatter uniformly next day and at earliest thereafter fork it into the upper spit. Later on refork the land to make certain that soil and lime are intimately mixed together. In addition to liming the soil in order to cure the sourness and kill the fungus disease, do not grow any susceptible vegetable there for at least two years. Beware of the great infectiousness of the disease and see that no soil or pieces of diseased root ever find their way to an immune patch of the garden. It is advisable that after such a bad gardening season every vegetable grower should lime the ground intended for cabbages, cauliflowers, radishes and so on next year. Half a pound per square yard will support the old statement that prevention is better than cure. Keep down charlock, cress and other cruciferous weeds in infested plots, as they also carry the disease.—C.

Sprouts and Savoys.

THE lower leaves of Brussels sprouts may be removed with a knife, the stems of them being cut through, leaving a stump of a few inches. The idea in doing this is to let sunshine and fresh air have free access to the sprouts themselves in order that they may mature in correct fashion without opening up. The top crown of leaves remains untouched to the last, but side leaves can be cut away in advance of the cropping of sprouts as they are picked off from below upwards. Do not feed sprouts so late as this; simply see that they are firm and not overcrowded. Remove a spadeful of earth from the soil near savoys which are almost mature, on the north side, pull the plants right over, and then tramp the soil over the roots to hold them in that position. This prevents the flat, solid hearts from suffering in rain, snow and frost, so that they keep fresh until required. Do not disturb the latest kinds which are just beginning to heart up nicely, unless it be to make sure that earth is firmly banked round the roots.—CLYDESDALE.

GREENHOUSE NOTES

The Care of Primulas Now.

FROM the time of sowing the seeds in May or June until the early part of the autumn, the cultivator does not experience much trouble with the resultant plants where a frame in a cool position is available. It is during the depth of the winter that the plants suffer most where the structures are unsuitable for them. Excessive damp, combined with a frosty air in the house, cause most harm. But it is a fact that primulas—sinensis, stellata and the Bulleyana hybrids—do not require a very high temperature—just high enough to keep the atmosphere buoyant. If the greenhouse is cool then the obconica and japonica sections are the most suitable. It is economical as regards heating to have double sheets of brown paper tacked on light wooden frames—such as may be made of builders' ceiling laths—to place between the glass and the plants. Sheets of lighter paper may be laid above the plants; a few pointed sticks keeping the paper from actual contact with the foliage. I have done this, had moisture actually frozen on the sheets, but by leaving the latter in position until a natural thaw came harm was not done to the plants. Keep the plants sturdy by avoiding overcrowding; place some plants on empty inverted flower-pots so that the brittle leaves are above others a little and all have room. All these things should be attended to now.—G. G.

Geraniums in Winter.

THERE is no doubt that the zonal geraniums (pelargoniums) are extremely useful for livening up a greenhouse or conservatory during the winter. These plants make a good show even in a cool house, providing actual frost can be kept away and, where it is possible to prevent the temperature from falling below 50 degrees Fahr., a fine display of bloom is certain almost until the spring. Many people grow geraniums from cuttings taken in June, but old plants, such as can be lifted from the garden at the present time, serve the purpose almost as well. The specimens should be removed carefully and then potted rather firmly in any garden soil, care being taken to see that the drainage is good. Do not give any water for about a week and remove any leaves that begin to die. If these are left it is very likely that they will become mildewed and the plants as a whole may be damaged. Keep the geraniums in an airy place, giving the plants as much room as possible. It is a good plan until mid-November to pinch out all the flower buds before these develop, as if this is done the plants will produce a wonderful show of winter bloom. When the pots are full of roots, it is an advantage to give the geraniums liquid manure which must be weak, once a fortnight. In growing geraniums indoors, damp is the greatest enemy. This may be fought with fire heat or, where this is wanting, free ventilation whenever the outdoor conditions are favourable. Now and again the geraniums will be all the better if the soil in the pot is allowed to become almost dust dry for a few days.—L. B.

Greenhouse Berried Plants.

RIVINA HUMILIS is a pretty little plant, graceful and decorative, which, at the end of the season, literally clothes itself with pendulous red berries, after the inconspicuous flowers fade. Although nominally a stove plant, it is, at this stage, much more useful and lasting if placed in a cooler and drier atmosphere. Another pretty berried plant is Ardisia crenata, an evergreen which also may be classed as a plant for the warm greenhouse. The berries are again scarlet, but a white-berried variety can be had. These berries hang for a long time. Callicarpas purpurea and lanata differ in bearing purple berries, produced plentifully on the semi-pendulous stems, which are just about the height of their glory at this time. A light, airy condition is best for keeping them hanging a long time. All three do best when grown in a loamy compost enriched with a little peat. Seed is readily obtained at this time, and it may be sown in spring. Cuttings may also be used in propagation, young shoots being inserted in April and rooted over bottom heat.—LANARKSHIRE.

Fuchsias for Greenhouse and Garden.

FUCHSIAS are not only useful for conservatory decoration, but as standards they make a very good effect if planted in the corners of flower beds with a groundwork of ivyleaf geranium or other summer-bedding subject or, again, at the back of the mixed flower border they add a touch of quality to the general appearance. If lifted and potted before severe frost reaches them and stored in a cool greenhouse for the winter, pruned and started into growth in the spring, they may be kept in good condition for many years. Cuttings may be rooted at almost any season of the year, but the present is a very good time to make a start. Select young growths free from flower-buds, cut through below the third or fourth joint and insert four in a 3in. pot in a compost of loam, leaf-mould and sand in equal parts. Place in a close propagating frame or in a deep box covered with a sheet of glass and keep moist until rooted. Pot off as soon as ready into small pots, using a similar compost, but with less sand.

Digitized by Google

Place in a light position in greenhouse and keep the plants growing all through the winter in a temperature of 60° to 65°, moving to larger pots as soon as the roots touch the side.

Do not pinch out the point of the leading growth if either standards or pyramids are desired, but in the case of the former remove all side shoots until the required height is reached, then remove the tip of the growth and a head can be formed by selecting from four to six of the topmost breaks, these in turn to be pinched at every second joint until flowering size is reached.

For pyramids pick all side shoots as they form at the second joint and keep all blooms removed until a well-balanced specimen is obtained.

For the later pottings it is a good plan to add some well-rotted manure and old mortar rubble to the soil.

Feeding with liquid manure should commence when the final pots are full of root and flowering has begun.

Treated liberally, cuttings rooted now will make good plants for conservatory decoration next summer, and in the following season can be planted outside in June.—F. W. W.

OUR SERVICE BUREAU

Remedies for Black Spot on Roses

I have great difficulty here in growing roses. The soil is poor and hungry, being mainly flinty gravel. Briar roses (Penzance), Pernetianas, R. Moyesii and Hugonis, etc., do magnificently. I give the hybrid teas and hybrid perpetuals a liberal dressing of cow manure every spring, but they do not make the growth they should. I am now going to try Clay's Fertiliser. This year most of them have had black spot badly. I have been picking off and burning the affected leaves and spraying with flowers of sulphur. Could you tell me with what I should treat the beds during the winter to disinfect them? Is Rosa Rugosa Conrad F. Meyer particularly subject to black spot?—H. H., Amersham.

Black spot is very likely arising from your Pernetianas. Conrad F. Meyer is also very susceptible to this disease. See that all fallen leaves are carefully gathered and burned. Apply lime in November at the rate of three ounces to the square yard of surface on the rose beds. Do not dig it in, but allow weather conditions to take it into the soil. Lime in fine powder form, such as is generally sold for horticultural purposes, is best. You will find Clay's a most excellent manure. Apply it after pruning in spring and hoe it lightly in. If black spot has been very severe it may have affected the stems of your plants. If so, this can be easily determined, and it will then be necessary to prune hard back in due season in order to get rid of the affected wood. The stock on which your roses are grown may not be suitable to your soil. It would pay you to experiment in this respect. There are other stocks than seedling briar.

Difficulties with Climbing Roses.

In February, 1926, I planted the following climbers in my garden: Albertine (2), Paul's Scarlet Climber, Tea Rambler, Emily Gray, Romeo, Alberic Barbier, Crimson Rambler, Mermaid and American Pillar. These were all cut down at once to ground level and all made good growth that summer, except one Albertine and Crimson Rambler. The latter, after running up about 8ft., suddenly, in late summer, collapsed, the foliage going a dark grey or black, and withering. The plant, however, threw up a further vigorous shoot this year, which also died back in the same way. I have now dug up the plant, but can see nothing wrong with the root. In September, 1926, one Albertine started to wither, the leaves turning yellow and dropping and the growth dying back. The plant grew well again until August of this year, when the same thing happened. This year Romeo has partly followed the Crimson Rambler, but some shoots are quite healthy, while others have died. Also, the other Albertine has shrivelled and died back. To my great disappointment, Mermaid, which made intensely vigorous growth and flowered well this summer, has collapsed in the same way as Albertine, leaves turning yellow and dropping. On the other hand, some new shoots appear to be still alive. Could you kindly let me know the cause of this and the remedy (if any)? I may say that the garden is a new one, but the ground was well dug and manured with hop manure before planting. The pillars upon which the climbers grow were treated with creosote before erection. Also, I feel I may have put rather a strong lot of hop manure under the roots. It was, however, well down and not touching the rootlets. The ground did, of course, contain a good deal of builder's rubbish, but I cannot think of anything which I found which would poison the plants. I have no failure with other things in the garden. All the other roses mentioned have done splendidly. I may say that I am not a novice at rose growing and I have never lost plants in this way before. THE GARDEN has helped me in hundreds of ways and a great deal of my success in the garden and in exhibition has been due to its help.—R., Teddington.

It is difficult to advise with the knowledge that one has arrived at the correct cause of your losses with your climbing roses, but there is a clue in your letter which leads one to suspect the reason. There is nothing more dangerous than creosote, and it is suspected that the posts upon which the ramblers have died back have been coated with this substance right down to the bottom. The roots are likely to have come into contact with it, and the plants have, consequently, sickened and died. It is not likely that the hop manure is the cause. It would be well, therefore, to examine the bottoms of the posts. We have frequently seen serious losses from this cause. Posts coated with creosote should be allowed to lie exposed to the atmosphere for at least three months before being used for roses.

Roses Susceptible to Black Spot.

I have read your article "How to Succeed with Roses" in THE GARDEN for October 15th. I agree entirely that "the modern rose is an exceedingly complicated organism," and I should be most grateful if you would tell me which are addicted to black spot? I think that I must have a complete collection of this type. I was most successful with the old roses—Georges Nabonnand, Corallina, Anna Oliver, etc., but since replanting three years ago, I have lost three sets from black spot. Heavy soil, well worked for twenty years. Farmyard manure only used. A garden in which most things do.—A. N., Exeter.

Black spot is a disease common to all varieties of roses of Persian ancestry. It is a historical fact that the beginning of the, so-called, Pernetiana race was the rose named Soleil d'Or. This had as one of its parents the old sort named Persian Yellow. Persian Yellow represents a type that is peculiarly susceptible to black spot, and this susceptibility has been transmitted to a great many varieties bred from parents derived from that particular ancestry. The Pernetiana roses are more or less liable to severe attacks of this disease, and it can be traced all through their development. Reference need only be made to such sorts as Rayon d'Or, Lyons Rose, Mme. Edouard Herriot, Lady Mary Ward, Iona Herdman and others of similar character. It is true that a considerable advance was made in attaining more vivid colours in roses owing to the infusion of Persian blood, but this has been gained at the expense of resistance to black spot diseases. You mention that you were very successful with such roses as Georges Nabonnand, Corallina and Anna Oliver. In the days when such sorts were grown, diseases such as black spot and mildew were rare occurrences. Those real tea types were most notable for their resistance to fungus diseases. Their day, unfortunately, has gone, but it is the opinion of the writer that they are most valuable as potential parents in the evolution of varieties that will prove highly resistant to disease. Some breeders are already recognising this and are now using that type for breeding purposes. Elizabeth of York may be quoted as one of the latest examples. It has all the virtues of the old teas coupled with the high coloured blooms demanded by modern growers. You should endeavour to form a collection of this resistant type. You state in your letter that your garden of heavy soil has been well worked for twenty years, and that only farmyard manure has been used. It may be that lime is now required. When was this substance last applied?

Plants for a Narrow Border.

By the side of a wall of my bungalow, facing south, I have made a narrow border 18ins. wide. This year I had daffodils early, and they did splendidly, and for later blooming I have had hollyhocks. These last, however, grew too tall, and lost most of their lower leaves. Can you suggest a perennial I might grow here, between 2ft. and 3ft. high—preferably one that would bloom off and on all the summer? Can you also tell me how and when to take cuttings of scarlet salvias? Just recently my geraniums, delphiniums, gladioli and lupins have been infested with caterpillars, which have eaten leaves and flowers alike, and done much damage. Can you tell me the cause of this, and what preventive methods to adopt.—H. J., Norwich.

Clumps of sweet peas would flower throughout the summer. Other kinds of plants combined would also serve your purpose, such as tall-growing antirrhinums, doronicums, delphiniums and Michaelmas daisies; but a dark-flowered antirrhinum and Calendula Orange King would produce flowers during the summer and autumn time. Young shoots of the salvia should be propagated in August or in March. Next year, directly any caterpillars are seen, spray with "Katakilla" or similar preparation, which can be obtained from any horticultural sundriesman.

Treatment of Old Vines.

I have a greenhouse at the end of my garden with grape vines which have been badly neglected in the past, resulting in practical failure. Could you inform me how best to feed the vines, and whether five are not too many in a 30ft. house? Also, have they been pruned too severely (each vine has but three shoots or branches). The house has a furnace which could be lighted in frosty weather. I should also be glad to learn the right time for grafting fruit trees, especially apples.—E. B., Streatham Hill, S.W.2.

The main rods of grape vines should be at least 3ft. apart. The side shoots should be pruned back to two buds late in December. One shoot only should be retained—if two grow—next year. Remove all the surface soil down to the roots in November and then cover them with 6ins. of good fibrous loam with 1lb. of finely ground bones to each barrow-load. A little fire heat will be beneficial next spring when the new shoots are growing. The right time to graft apple trees is early in April.

THE GARDEN

VOL. XCI.—No. 2919. NOVEMBER 12, 1927. PRICE TWOPENCE.

EARLY FLOWERERS IN THE ROCK GARDEN

IT is usually with a sigh that the rock gardener finishes the cutting back and clearing up of autumn; it seems a long time until the special fascination of alpine gardening will be all-absorbing again.

It is possible, however, with a little forethought and care in planting, to have quite a bright show of colour in the rockery when the rest of the garden has hardly turned over from its winter sleep. The first days of March—even the last half of February—may be quite gay with flowers, chiefly blue and yellow, the colours of spring.

Saxifrages of the apiculata type, both white and yellow, are most floriferous and eager "to oblige." January is hardly over before they are out, and they rapidly form large patches. They do equally well in flat ground and among the rocks. Planted at the top of a mound like an inverted basin, they will soon cover it completely.

Some of the choicer saxifrages are also very early. The Gloria variety of S. Burseriana overtakes its ancestor by several weeks, producing its lovely white penny-size blossoms so soon that it usually demands a sheet of glass for protection from winter storms.

Other varieties of February and March flowering saxifrages are Boydii (lemon flowers on grey tufts), Elizabethæ (yellow), Faldonside (very large lemon), L. S. Godself (single-flowered yellow), oppositifolia (rosy), Sundermanni (pink) and Boryi (white on close rosettes).

Few of the mossy saxifrages are very early. Bathoniensis and densa alba, however, make fine splashes of blood red and pure white colour at the beginning of March. The latter is very low growing, almost a carpeter. Both of these will form curtains if planted to fall over stones.

The giant-leaved S. Megasea ligulata is gorgeous in February where it is well established. It covers itself with masses of warm pink tresses, but it needs a newspaper over it in very severe frost.

In the iris family there are several invaluable early kinds. There is that Algerian winter treasure, Iris stylosa, which flowers from November to March even in the severest weather. All it requires is a warm, dry corner under a south wall, with its roots pressed hard against it. Given these conditions, it can be trusted to produce successive quantities of its lovely lavender blue blossoms which look so frail and are so strong, all through the winter.

Of the dwarf irises, Pumila azurea and P. cœrulea are the earliest, coming in with the March winds. They should be separated every two years, as they increase very quickly and do not resent disturbance so much as most of their kind. Replanted in September, every rhizome will send out a flowering shoot the following March.

Some of the miniature bulbous irises planted in warm sandy loam will begin to bloom in January. Their exquisite tiny flowers are easily spoilt by rain or snow, but a sheet of glass is an efficient protector. One of them, however, I. reticulata, a single flower of which will scent a large room, is almost weatherproof. Its rich purple, splashed with gold, is very effective. These irises can be had in shades of blue, purple, white, lavender and yellow.

The hellebores (Christmas roses) are all winter flowerers. They will give masses of white, pink and red blooms from November to March, but, though the plants are hardy, the flowers are delicate, requiring some protection from snow or heavy rain.

The vernal gentian and the miniature grape hyacinth are lovely little sky blue flowers only about 4ins. high and usually open at the end of February. The latter is specially attractive if the bulbs are planted under a close-fitting carpeter, such as Arenaria balearica or Mentha Requiemi. They make little foliage, and it can be easily removed before the carpeter blossoms come out in May.

Primula denticulata is another early-comer. The dense flower heads often appear in November, and as they easily rot in bad weather, it is, perhaps, best to grow this primula in pots in an unheated house or in a window, planting it out when it is in flower, when it will only need a little weather watching.

"Glory of the Snow" (chionodoxa) should be freely planted in colonies for early flowering, though it will not be long before it produces, in mysterious fashion, offshoots all over the rock garden, far from the original patch.

Lastly, there are the blue primroses, which generally precede their common yellow relations. In a mild winter, neats of reddish buds may be found ready to open from Christmas onwards. Planted on sloping ground in an irregular drift, with snowdrops somewhere near them, they will form a lovely spring effect.

A look out should be kept for the appearance of these early blossoms during the next few weeks, and when it comes to planting time next season, their value should be borne in mind. Each is worthy of a corner in the rockery.

This Week's Work

For Gardens in the South and Midlands.

Plant flowering shrubs, herbaceous perennials, roses and fruit trees if weather and soil conditions are suitable.

Continue planting out Darwin tulips.

Take cuttings of bush fruit.

Feed established fruit trees with kainit and basic slag.

Complete the renovation of herbaceous borders.

Prepare sweet pea trenches.

Make a sowing of broad beans on a warm, sunny border.

Lift seakale and force in boxes of soil in a warm greenhouse.

This Week's Work

For Gardens in Scotland and the North.

Plant liliums in large pots, three in each.

Commence forcing asparagus and rhubarb if wanted early.

Arrange vegetable rotation and prepare the ground.

Pot up Berlin crowns of lily of the valley.

Take out sweet pea trench.

Feed Brussels sprouts once a week.

Take cuttings of gooseberries.

Complete the planting of early tulips.

Cleanse fruit trees under glass.

Pot spiræas for spring flowering.

Plant hardy liliums in a sunny border.

Give winter protection to less hardy alpines.

Digitized by Google

IDEAS FOR A SHRUB BORDER

A shrub border will be found to add much beauty to any garden. Once planted it forms a pleasant and permanent feature that demands little attention in upkeep. This is the best time to plant up a new border or to make additions or renewals to an already existing shrub border. In the following article is given a list of suitable and choice shrubs, which every amateur will find both useful and decorative.

AT this time of year attention is paid, if you are wise, to the question of shrub renewals and additions. The reason why this should be considered at the earliest possible moment is that it is only while the foliage is still on trees and shrubs that it is really possible to judge correctly when thinnings or additions are necessary. In the winter, when the branches are bare, it is next to impossible for a gardener, however expert he may be, to judge correctly the summer appearance of his shrubbery. On the whole, if additions are made without due forethought the error is usually made in excess planting, rather than underestimating the space at your disposal. A golden rule is that the more floriferous and magnificent a shrub is, the more space you should give it, so that its beauty may not be marred by being crowded by other plants in its immediate vicinity. This is most important, for more fine specimen shrubs are ruined by being crowded than from any other cause. On the other hand, in the winter it is impossible to estimate correctly the value of the foliage of your shrubs, and much can be done by judicious inter-planting to improve the value of your shrub border.

Renewals are a much more difficult problem. Let us take an example. In the case of old lilacs, it often happens that the original graft has been smothered by the stock plant through lack of care, with the consequence that instead of the fine flowered variety, nothing remains but the squinny flowers of the original stock. Probably it is a large bush and the owner has qualms at removing it and leaving an unpleasant gap in what may otherwise be a shapely border. Naturally, every case requires individual treatment, but in the case of renewals in an old, well established border, it is usually advisable to choose plants for renewal that are quick growing: deutzias, syringas, philadelphus, buddleias, and the large spiræas, such as S. arborea, S. Aitchisonii and S. sorbifolia are excellent among large plants. If those of smaller size are required, such shrubs as Potentilla fruticosa, Berberis Wilsonii and some other berberis, some of the better hypericums and the dwarfer deutzias will soon fill the space. When renewals are made, remember to remove the stump of what is removed—cutting down is not sufficient—and to work the soil well, while you have the chance. It will let the new plant get away all the quicker if the ground is worked and enriched. But in renewals and additions remember, above all, that overcrowding is a grave error.

It is generally supposed that a shrub border requires little planning and that, provided that due care is taken to plant the tallest growers at the back and dwarfer shrubs in the front, arrangement is not difficult. That may be so, if a massed and tight effect is aimed at, but in that case the shrub border will be simply a screen, there will be no individuality about the plants. Let us give an instance. Buddleia alternifolia is one of the most graceful shrubs, with its arching branches and lavender flowers. But this buddleia flowers on the old wood and so it cannot be pruned, with the consequence that it must have room to expand. Now the middle of a shrub border is useless as a situation for this charming individual. It will either infringe on the ground of its neighbours, and in time shut them off from sight, or it will have to be pruned, when its effect disappears. So the place for it is either at a corner or at the end, where it can arch over the grass without harming either itself or its neighbours. In fact, for an ordinary shrub border, rather stiff and erect shrubs should be grown, for their limits are known and so the area allowed them can be legislated for. It is impossible in the space at our disposal to give lists of all suitable shrubs, but the following are excellent for shrub borders:

Abutilon vitifolium.
Arbutus Menziesii.
Arctostaphylos manzanita.
Azaleas in variety.
Berberis Darwinii, stenophylla and others.
Buddleia variabilis and varieties; B. alternifolia.
Ceanothus Gloire de Versailles, varieties and species.
Clethra alnifolia.
Corylopsis spicata.
Cytisus in variety.

DEUTZIAS ARE EMINENTLY SUITED FOR A PROMINENT POSITION IN THE SHRUB BORDER.

NO SMALL GARDEN SHOULD BE WITHOUT ONE OF THE CHOICE DECORATIVE VARIETIES OF THE MOCK ORANGE.
This species is Philadelphus Lemoinei smothered in blossom.

Digitized by Google

Desfontainea spinosa.
Deutzias in variety.
Daphne Mezereum.
Escallonia macrantha; E. langleyensis; E. Philippiana.
Ericas in variety for edgings.
Fremontia californica.
Gaultheria Shallon.
Hamamelis japonica; H. mollis.
Hypericum patulum Henryi and other species.
Kalmia latifolia.
Olearia Haastii, and a few of the taller growing species.
Osmanthus Delavayi.
Pernettya mucronata.
Pieris japonica.
Pyracantha coccinea, var. Lalandei.
Potentilla fruticosa.
Plagianthus Lyallii.
Philadelphus coronarius; P. purpureo-maculatus; P. microphyllus; P. Boule d'Argent; P. Voie lactee; P. Virginal Lemoinei.
Prunus and pyrus in variety.
Raphiolepis japonica.
Rhododendron chartophyllum præcox; Rh. yunnanense, and others of the triflorum series.
Spiræa Aitchisonii; S. arborea; S. sorbifolia.
Stranvaesia undulata.
Syringas in variety.
Viburnum Carlesii; V. fragrans; V. Tinus; V. tomentosum plicatum.
Veronica Traversii and varieties.

As well as aiming at a border which is to show off the individuality of its constituents, some attempt should also be made to select the plants so that the border will be a representative one and will contain something of interest at the main seasons of the year. Early and late flowering subjects must be included, while autumn colourers and berriers are also worth introducing. Here again, the physical conditions of the site must, to a certain extent, govern the selection of the plants and the nature of the soil must receive consideration, whether it be limy or lime-free, heavy or light, etc. Some shrubs, such as Osmanthus Delavayi, Forsythia intermedia and others, do well in a position facing north, with no overhead shade; while others, of a more tender nature, prefer a situation with a southern aspect. Gaultheria Shallon, Ruscus aculeatus (the Butcher's Broom), Euonymus radicans, Sarcococca ruscifolia and Vinca minor and major, do well in a semi-shaded position.

DWARF CONIFERS for the LAWN and ROCKERY

EVERGREEN conifers have for a very long period been popular with owners of gardens, more particularly small gardens. In a small state they are wonderfully attractive plants, and they make such a strong appeal to those with a limited knowledge of trees that they are indiscriminately chosen for a variety of positions, many of which are quite unsuitable for the particular species. It is not unusual to find species which naturally form trees of the largest size planted in tiny gardens and in the forecourts of suburban residences, where, after a few years, they make it impossible to cultivate other plants near by, and at the same time preclude much light and air from dwelling-rooms. Sentiment does not admit of their removal, and only too often the owners or occupants of the houses submit to the discomfort of darkened rooms and a stuffy atmosphere, rather than harden their hearts and remove such trees. Cedars and hemloc spruces, firs, cypresses and monkey puzzles may all be found occupying cramped positions, where they are quite out of place and are not seen to advantage. At the same time there are many dwarf kinds of conifers that are eminently suitable for planting in small gardens, on lawns of modest dimensions, or even in the rock garden among choice alpine plants.

CUPRESSUS ALLUMII, THE FINEST OF THE BLUE CYPRESSES, OF NEAT, COMPACT HABIT.

There are some species of dwarf habit, but the majority of the dwarf conifers are varieties of well known species. Some of them are almost identical with the stunted forms of various species that are found at high elevations or in exposed positions; trees which normally grow 100ft. or 150ft. high, but by cold and exposure are reduced to dense bushes of 1ft. or 2ft.; and they may very well have originated from these stunted forms. Others have come about by propagating sports or abnormal branches from established trees; by chance seedlings differing from the type; and in various other ways. It is even suggested that some of the very dwarf, dense kinds of spruce and other subjects have been obtained by propagating from the curious tufted growths that sometimes appear upon trees and are known as witches' brooms. However they may have originated, they maintain a dwarf, dense character, only occasionally breaking away with a long, wild, vigorous shoot, as if an effort were being made to return to the normal form.

All gardens are not suitable even for dwarf conifers. It is only courting disaster to plant these or other conifers in gardens in or near smoky towns, or where the atmosphere is charged with chemical fumes. They are essentially plants for the country and small towns where the atmosphere is, at any rate, moderately free from impurities. Moreover, they are, in most cases, unsuitable for very dry, sandy or gravelly soils, unless some considerable trouble is taken in preparing the ground for their reception. Where one of these dwarf conifers may succeed very well in a rockery where the soil does not appear to be very plentiful, it may prove a distinct failure in a dry position in the ordinary soil of the same garden. As a rule, it is easy to see in any neighbourhood whether dwarf conifers are likely to thrive by the condition of the trees that already exist thereabouts.

It is usually wise to plant conifers in permanent places while they are comparatively small. If large plants are purchased, care should be taken to find out whether they have been regularly transplanted and that they are lifted, packed and eventually replanted in a proper manner. When dwarf conifers are to be grown in crevices between stones in the rock garden they should certainly be planted while very small, for they will then establish themselves and grow to fit the positions better than would larger plants.

The spruces offer a wide field for selection. There are dwarf forms of several species, and even one or two species are so slow and compact growing that they are well adapted for even small gardens. The West American Picea pungens and more particularly its glaucous-leaved forms, glauca, argentea, Moerheimii, Kosteriana and Speckii, form very beautiful conical or pyramidal trees, often not more than 6ft. or 8ft. wide at the base and less than 15ft. high. They take many years to reach that size and, though they may grow taller and wider, they are unlikely to grow out of bounds. The leaves of the type are bluish, but the colour is intensified in the varieties. Unfortunately, this species is subject to attack by spruce aphis, Aphis abietina, which first turns the leaves brown and then causes them to fall. On the appearance of this pest the plants should be thoroughly sprayed on several occasions, at intervals of a few days, with a paraffin wash. Of the common spruce, Picea excelsa, there are many dwarf varieties. They vary a good deal in habit and stature. Some form compact, cushion-like masses less than 2ft. high, others grow into dense bushes 10ft. or more in height; some are of loose habit with long sprawling branches, while others are of prostrate growth. P. excelsa var. Clanbrasiliana forms a dense rounded bush 4ft. to 10ft. or more high and up to 10ft. through. It takes many years in attaining its largest size and frequently does not exceed 5ft. It is too coarse for the rock garden except an out-of-the-way place can be found

ANOTHER CHOICE GOLDEN-LEAVED VARIETY CUPRESSUS ERECTA VIRIDIS AUREA.

Digitized by Google

in the background, where shelter is desired for some other plant, but it is well adapted for planting on a lawn of modest dimensions. The variety pyramidalis is taller than the last-named, but it also is of compact habit and suitable for a small garden. More suitable for rockery planting are such low-growing kinds as nana, Gregoryiana, humilis, pygmæa, echinæformis, dumosa, capitata, diffusa, Sargentii, nidiformis and Merkii, all varieties of P. excelsa. Varieties such as pendula, procumbens, repens and prostrata are all prostrate forms of the common spruce. They should be planted so that their branches can trail over a rock; one or two form picturesque additions to the rock garden, but they should not be overdone. Picea orientalis nana and P. o. gracilis are of dense, compact growth with very small and neat leaves. They take many years to reach a height of 3ft., and are excellent for the rockery. P. Albertiana var. conica forms a dense cone of rich green leaves. It grows very slowly and is suitable for the rock garden for many years, although eventually it may become too large. For the border of a small lawn it is well suited. It is a dense, compact form of the western North American P. albertiana.

Among the junipers are numerous dwarf kinds that are well adapted for small groups on lawns, for covering banks, or for the rock garden. They thrive in chalky soil, although such soil is not absolutely necessary. Of the common Juniperus communis there are several attractive forms that deserve a prominent place in the rockery. J. communis var. nana is a prostrate shrub rarely a foot high, which forms a carpet of glaucous green leaves. J. communis var. compressa is a very slow-growing shrub, popular for rock gardens. It does not readily grow out of bounds, although it may attain a height of several feet. It appears to be a slow-growing form of the variety hibernica, or it may even be the same plant. However, the so-called Irish juniper eventually attains a height of 12ft. or 15ft. Other forms of the common juniper are echinæformis, aurea and nana aurea. The last two have golden variegated leaves. The numerous varieties of Juniperus Sabina—the "Savin"—are rather coarse for the rock garden, although they form very good evergreen groups for the border of a lawn, or they may be used with effect for covering banks. Good varieties are humilis, Knap Hill and tamariscifolia. J. horizontalis, J. procumbens, J. chinensis var. globosa, J. chinensis var. nana, J. conferta, and the varieties of J. virginiana, dumosa, globosa, and reptans are all dwarf, slow-growing plants.

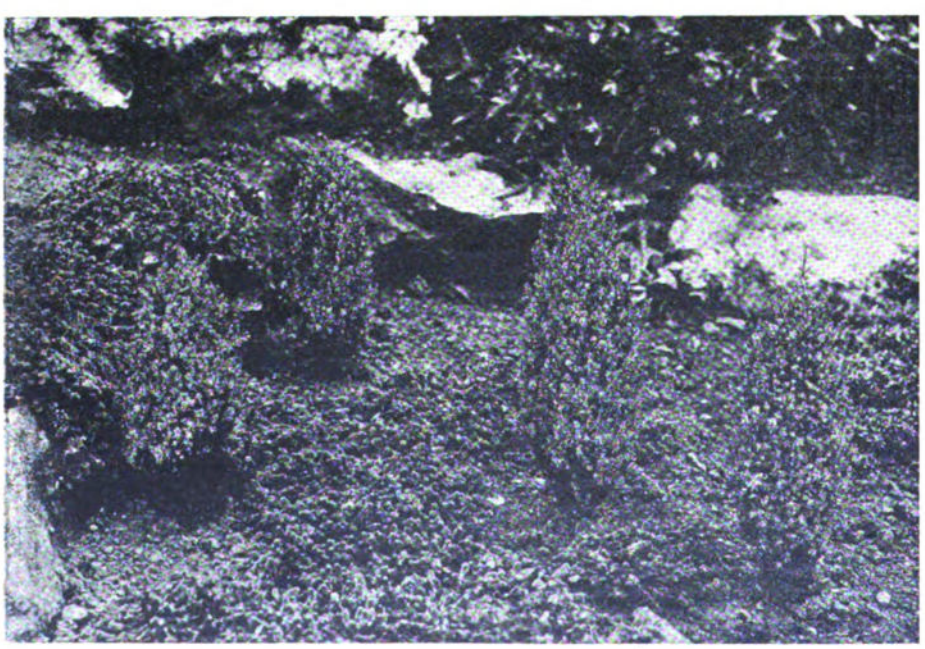
A WELL PLACED CUPRESSUS BY THE MARGIN OF A SMALL ROCK POOL.

Among the cypresses are several kinds that are well suited for the margins of small lawns. Of Cupressus Lawsoniana there are numerous dwarf and compact varieties. The variety nana forms a compact bush 4ft. to 5ft. high and 5ft. or 6ft. or more through; filiformis compacta forms a globe-like bush, peculiar by reason of its slender, pendulous branchlets; nana glauca is very like nana, but has glaucous foliage. Fletcheri forms a dense pyramidal bush, peculiar from the fact that the leaves retain the juvenile shape. Variety darleyensis is a plant about the size of nana, from which it differs by having golden leaves. Variety juniperoides, also called ericoides, is a low-growing plant with very graceful shoots and leaves. In addition to these, there are numerous other forms of Cupressus Lawsoniana that are slow enough growing for the smallest gardens.

The Japanese Cupressus obtusa has produced a number of beautiful and interesting forms which grow very slowly and are suitable either for the rock garden or for grouping on the margin of a lawn. Some of these varieties have golden foliage, and it is wise to reserve them for the lawn relying upon those with green leaves for the rock garden. C. obtusa var. pygmæa seldom exceeds 2ft. in height. It is peculiar by reason of its stunted growth and flat branches. It is very suitable for the rockery. There is a form of this variety with golden leaves. C. obtusa var. nana is a dwarf dense plant with very crowded branches; an exceptionally dense form has been given the name of densa, while aurea is a golden-leaved counterpart of nana. In C. obtusa var. Sanderi the leaves retain their juvenile form. It may grow several feet high. C. obtusa var. tetragona forms a conical bush with dense, small-tufted branchlets. There is a golden-leaved variety, aurea. Of Cupressus pisifera, the varieties plumosa aurea, plumosa aurea compacta and squarrosa sulphurea are all attractive plants that are slow enough growing for planting in gardens of modest dimensions.

There are several thuyas that are well adapted for small gardens or rockeries. Of Thuya occidentalis, the varieties minima, ericoides, compacta and globosa should be noted; while of Thuya orientalis there are nana, cristata, dumosa, densa glauca, and various others of slow growth. Then there are several other varieties rather larger than those mentioned above, such as Hillieri, elegantissima and aurea, that are very suitable for lawns and small gardens. Several species of pinus have produced dwarf varieties, such as P. sylvestris var. globosa, var. aurea, var. nana and others. Those with natural-coloured leaves are very suitable for the rock garden. Of the Weymouth pine, Pinus Strobus, there are the varieties pumila, minima and prostrata; while of the Japanese P. parviflora there is a dwarf form, nana.

In addition to those mentioned there are dwarf forms of taxus, podocarpus, Douglas fir, larch, Tsuga and of several other genera, but those enumerated offer a wide choice to would-be planters. W. D.



AN EXCELLENT DWARF CONIFER FOR SPECIMEN PLANTING IN THE ROCK GARDEN, JUNIPERUS HIBERNICA COMPRESSA.

CLIMBING AND RAMBLER ROSES

Some of the Best Varieties.

IN dealing with the climbing roses, the first kinds to come under review are the rampant forms of the hybrid teas. It will be observed that a good many of the climbing roses bear the names of well known hybrid teas, and almost without exception they are simply sports from the dwarf sorts of similar name. Several of these sports of a climbing character are not fixed, and they are apt to revert back to the dwarf form of the variety from which they originated. Climbing Lady Ashtown, Climbing Mme. Abel Chatenay and Climbing Sunburst are examples of such reversion. No matter how carefully these may be propagated, and no matter how particular the nurseryman may be in taking "eyes" for budding from shoots that are decidedly of a climbing character, a large number are sure to go back to bush or dwarf form. On the other hand, several of the climbing hybrid teas are practically fixed, and the grower rarely finds a case of reversion to the parent among them.

Climbing Caroline Testout is, to my mind, the finest and most reliable of the climbing hybrid teas. It is really a wonderful climber, and it seems to produce flowers that are superior to those borne by the dwarf form. It has been stated that this rose is not a sport but is a seedling. If that is so—and I am inclined to think that the statement is correct—it will explain its constancy as a climbing rose and the lack of reversion which is justly attributed to it. It flowers with wonderful freedom, and it has a most vigorous constitution. Climbing Paul Lede is another vigorous climber that is also very constant in character. This variety is not sufficiently well known, and lovers of climbing roses who have not yet tried it should make a point of doing so. The colour is a carmine pink shaded with saffron yellow, and the flowers are large and are of attractive formation. It is also free in its flowering character and is a real hybrid tea in this respect.

Climbing Mme. Edouard Herriot is a beautiful climbing rose. One of its most important features is its earliness in coming into flower, and it is one of the first of the climbers to show blooms in early summer. Climbing Mme. Melanie Soupert is another good variety, and Climbing Lady Hillingdon is also worthy of note. A climbing form of Mrs. Henry Bowles has been sent out this season, and it is a very vigorous and free-flowering sort that may be absolutely relied upon. One or two sorts are somewhat shy in flowering, and Climbing General MacArthur and Climbing Mrs. Herbert Stevens are examples. Both grow with extraordinary vigour, but they are notable for their paucity of blossoms. There is a climbing form of Ophelia, but as we now have a Climbing Mme. Butterfly I think we need not trouble any longer about the Climbing Ophelia. It is needless to elaborate any further upon the climbing hybrid teas, but it may be mentioned that there are now climbing forms of Chateau de Clos Vougeot, Golden Ophelia, Hoosier Beauty, Irish Fireflame, La France, Liberty, Los Angeles, Mrs. Aaron Ward, Mrs. W. J. Grant, Richmond and Sunstar. Climbing H. V. Machin deserves special notice. The dwarf form is very difficult to grow; it remains a poor stilted thing in most gardens. Those who have trouble with it can overcome the difficulty by growing the climbing form.

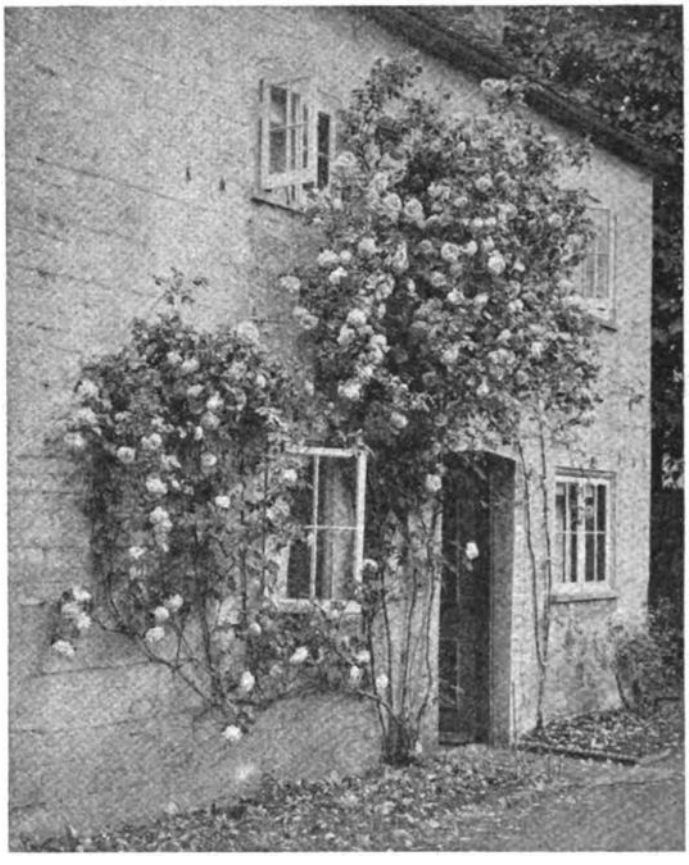
Lemon Pillar, reputed to be a seedling from Frau Karl Druschki and Marechal Niel, is a splendid rose, and it is simply unrivalled for cultivation in the cold greenhouse or conservatory. With the protection of glass the flowers are perfect; the formation is ideal; the colour is an entrancing shade of white with a faint tone of lemon through it that gives the appearance of a sheen of green over the flower. I have seen as many as four hundred flowers open at one time upon an established plant in a conservatory. It also does well in the open. Black Boy, an Australian rose, has flowers of a very dark crimson. Allen Chandler is hardly a climber, and will be dealt with when we come to Pillar Roses. Lady Gwendoline Colvin deserves a wider popularity than it has at present. It resembles Lady Pirrie in colour, and is an early flowerer.

Gloire de Dijon, William Allen Richardson and Mme. Berard are well known as reliable sorts. The first and the last are tea roses, and W. A. Richardson is a noisette. In a mild season Gloire de Dijon flowers almost throughout the whole year. Alister Stella Gray, another noisette, with ochre yellow flowers fading off to white, was a favourite at one time, but it seems to be falling out of the lists. Mermaid, with its glorious single sulphur yellow blooms and its very conspicuous stamens, is very beautiful and has become justly popular. Una, a single pure white, is a vigorous sort and a most prolific flowerer. The buds are buff yellow. This rose is said to be derived from the wild rose (Rosa canina) and Gloire de Dijon. It is worthy of a place in gardens where free-flowering climbers are desired.

Several old favourites have now almost dropped out of commerce, and I am mentioning them here as I think they deserve to be revived again. Reine Marie Henriette, for example, has practically gone out of the catalogues. What is the reason? Is there, among crimson climbing roses, anything to beat it to-day? I have seen this rose during the last year or two beautifully established on walls in old gardens, and every time I see it I ask myself why it has been discarded. The same remarks apply to Charles Lawson, an old Bourbon rose of great vigour and remarkably free-flowering qualities. The colour is rosy pink, and the fragrance is delicious. One firm is re-introducing these fine old roses.

Mme. Alfred Carriere is worthy of note. It is a rampant grower, and its white flowers have a fine perfume. It takes a year or two to become established, but when that has been done it is, surely, one of the most satisfying of roses. If a grower looks to the future he will certainly plant this rose. It will clothe a wall or building very rapidly, and when it is established it will be a great sight season after season. Climbing Cramoisie Superieure, a rampant form of the grand old China of that name, is undoubtedly the most perpetual-flowering variety among climbing roses. The colour is a deep crimson. For a cottage wall there is nothing finer.

American Pillar needs no description, nor does Paul's Scarlet Climber. These, of course, are more like ramblers in character than the sorts already dealt with in this note, but as they are very distinct from the wichuraiana hybrids they are included here. They are good for walls, pergolas, posts, or any erection upon which roses may be grown, whereas the wichuraianas, or, at least, most of them, are not suitable for walls.



A CLIMBING ROSE MAKES ONE OF THE MOST ADMIRABLE WALL DECORATIONS, ESPECIALLY OVER A DOORWAY.

The climbing roses dealt with here are all most suitable for walls, pergolas or high fences. Their fault is their inclination to become leggy at the base after they have become established, but this can be remedied by proper attention in regard to pruning, and this will be dealt with in due course. It should be the practice when planting climbing roses to shorten the shoots back to about 3ft. from the ground. Many growers tie up the long shoots of climbers very carefully, but that is work all to no purpose. If climbing roses are to be satisfactorily established they must be pruned the first season after planting, and pruning consists in cutting the shoots grown in the nursery to within 6ins. of the soil level. Climbing roses planted now, for example, should have the long shoots shortened back as stated, and at the end of March or beginning of April they are cut down drastically. Wichuraianas and allied ramblers will form the subject of my next article.

THE BUSY MAN'S PAGE

Wattle Hurdles in the Garden.

WATTLE hurdles are useful garden accessories. They consist of a framework of stated size, across which are woven split hazel branches, the whole having the appearance of basket work on an enlarged scale. They make excellent wind screens. Three of them fixed round the garden frame on the windward side shelter it from the cold winds of winter and make the frame comparatively secure. Or a wall of hurdles erected along one side of the garden serves as a useful wind screen, warding off direct windstorms and draughts. Although primarily meant to serve as wind screens and protective hedges in the garden, they may also be utilised as dividing hedges, boundary fences or as screens to hide certain parts. For the former purposes they are quite good because, having essentially a stout post at either end, they are solid and stout. Be it noted, however, that to make a neat job a wooden rail of ordinary fencing material should be used in addition to the hurdles along the top to keep them from warping and twisting. It is impossible to see through these hurdles, hence as a screen they are ideal, and possessing

WATTLE HURDLES MAKE EXCELLENT WIND SCREENS.
They are made of split hazel branches.

as they do, especially after a little weathering, a truly rustic look they never seem out of place. They can also be made circular in two pieces for the purpose of protecting shrubs. The hurdles are sold in various sizes. A very useful size for a fence or a wind screen is 6ft. by 3ft.; smaller sizes are very good to use in spring in order to prevent cold draughts playing on early crops; larger sizes make excellent screens. As a rule each hurdle is sold with one stout post. By employing these hurdles in the garden it is an excellent way, at little expense, of protecting one's stock of plants. Any of our readers who are interested should write to Messrs. Ernest Smith, who specialise in the making of these hurdles.

Garden Mats for Winter Protection.

A STOCK of garden mats is undoubtedly an acquisition during the winter season, from October until May. These mats are made of stout, woven material. In size they vary considerably, but two useful sizes are 4ft. by 3ft. and 7ft. by 3½ft. When not in use they ought to be dried and kept dry, not merely because when treated in this way their "life" is considerably prolonged, but because a dry mat on a frosty night is better than several wet ones. Some of the mats should have a stout cord carefully sown on to each corner. Garden mats are used to cover the frames during frosty weather. They ought to fall over the sides to keep cold wind from leaking in and, to hold them in position, a rope over the top, a couple of boards or ties at each corner are required. Hotbeds, frames and other things can often be safeguarded by throwing a mat or two on the windy side, and a mat erected as a permanency can become a very fine wind screen. Mats can be suspended round or in front of fruit and other trees. Thrown on a frame work over plants in the open, over crops in the border or on half-hardy plants in the rockery, these mats will keep out frost very well and shield the subjects from stormy weather. A hundred and one other uses might be enumerated, but we cannot go into detail. Readers who do not yet know their value should get a few—they cost from 6d. to 1s. 9d., according to size and quality—and they will then regard their store of mats as a real asset.

Liming a Lawn.

AFTER a wet year like this, as well as in all cases from time to time, say, every four or five years, a lawn derives much benefit from a dressing of lime. When the soil is heavy and of a retentive nature we should even go beyond that and apply lime every third year or so. Active or caustic lime must not be used, otherwise the grass may become discoloured for a time. Ground carbonate or finely ground shells may be used, and such are probably best when the soil is of a light and porous nature. Having obtained or prepared the lime, let it be applied this month, or next, at the rate of half a pound per square yard. It may be mixed with sand or sifted soil or applied alone as desired. Although absolute exactitude is not necessary in making the application, a line may be set across the lawn cutting off a yard breadth; this, paced out, will represent square yards, and the correct amount may be applied there, the process being repeated until the lawn is completely treated. Apply on a dry day. Lime, however, is apt to encourage clovers (which may be killed out with one of the easily procured proprietary brands on the market, or sulphate of ammonia in spring), but it also kills moss, discourages weeds, improves the "feel" of the lawn and rejuvenates the grass.

Winter Treatment of Fuchsias in the Greenhouse.

FUCHSIAS ought to be kept in a cool place during winter free from frost and damp, the main idea being to give them a period of rest for a few months. It is not always convenient to keep a greenhouse at the temperature suited to such plants, having regard to other occupants which demand warmth, but it is serving the best interests of fuchsias when they can be kept cool and examined from time to time. No attempt should be made to cut them back until towards February, when the new growth appears. At that time they are best brought into gentle warmth, and when shoots have well broken they can be repotted. This involves shaking some of the old soil away without disturbing the roots more than one can help, after which they should be syringed in order to induce free growth. It is not always necessary to shift them into larger-sized pots so much as giving them a start in fresh compost, which should consist of good fibrous loam, leaf-mould or spent hops with a little coarse sand. In shifting them it is desirable that the pots be clean and that ample drainage is provided. From the time fuchsias begin to make active growth a genial and somewhat humid atmosphere suits them best.

Standards.—In the case of standards, the treatment is rather different. They should be encouraged to continue growth during winter, but little heat is needful for this, the idea being to keep them moving gently. As spring approaches more water should be given fuchsias, and they can also be helped with weak applications of liquid manure or fertiliser, but whatever liquid is given it should have the chill taken off, as otherwise it is easy to give them a check. After the young shoots have made several inches of growth they may be stopped to render the plant shapely, and the cuttings dibbled in the warm, moist bed of a propagating pit if more plants are wanted.

Fuchsias when in actual growth ought to have their shoots tied to thin twigs or sticks, as if this is not done they not infrequently get broken by weight of water from the syringe. A little old soot placed in the water will have the effect of improving the colour of the foliage, besides invigorating the plants.

Dividing Herbaceous Plants.

NOW is the time to renovate and replant the herbaceous border. Sometimes the tall plants, such as Michaelmas daisies, perennial sunflowers and the other herbaceous occupants, are just chopped in half with a chopper, and replanted. However, this is not the most successful method, for it is not the number of shoots to a clump that counts, but the number that can be given free action so that they flower well. Herbaceous plants grow away from the centre, so that it is the outside ring that counts and not the central stool, which is old stock. So instead of chopping off large pieces, the stools should be carefully divided, and the small outside tufts planted in preference to the large, hacked-off pieces.

Draining a Small Garden.

BEFORE setting about draining a small garden it is most essential to see that a suitable outlet is available for the flow of water. This outlet may be into a ditch, into a pond, into a well or into another pipe, but when these are not available then a deep well is required penetrating down to a porous gravelly stratum; the well need not be left open, for if filled up to drainage level with stones or clinkers and covered with soil it works quite efficiently. Drainage pipes are laid down the slope of the garden at intervals of 10ft. to 15ft. In a level garden the ditch dug should vary in depth so that the water will flow to the outlet. Dig the ditch to a depth of 2ft. in heavy land or 2½ft. in light land; see that the bottom is smooth and lay the pipes as close as they will go. Place stones in the ditch over the pipe if there are any lying about and fill in earth loosely, allowing it to settle naturally during the winter. If drain pipes are not available, fill the ditch to a depth of 6ins. with rubble, clinkers or coarse ashes, place a layer of turf on top and fill in soil. Smaller gardens still can be drained by simply digging a hole in the centre. Leave this open all winter, toss into it stones, tins and rubbish of any kind, cover with turf and fill soil on top in spring.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Five Rods of Fruit.

NEARLY all garden fruits are gathered, and with the approach of the season of the sere and yellow leaf, we think of new plantings. The best time to plant the apples or loganberries on which you have set your heart, is when the sap is descending. This is a rule-of-thumb method of gardeners, and it is borne out by scientific knowledge. The extra activity which goes on inside a plant, in preparation for the winter, enables it to form new roots, and heal wounds caused by moving. I am asked by one reader to give a few suggestions for planting five rods of land with fruit trees. Five rods is roughly 10yds. by 15yds. On such a piece of land quite a variety of fruits can be grown.

The first thing would be to bastard trench the land, 2ft. deep., and dig in two loads of manure and 2cwt. of lime. The rows of fruit bushes should run north and south. Plant on the north and east sides Morello cherries and loganberries as a protection from the cold winds. Five loganberries and two cherries would be sufficient. Raspberries are planted in rows, 3ft. apart in the row, and 5ft. between the rows. Lloyd George is the best variety. Currants are planted 5ft. apart each way. Red Dutch and Black Baldwin are two of the best varieties. Gooseberries are planted the same distance apart, Keepsake, Lancashire Lad and Whinham's Industry being good sorts. On such a plot there would be room for two rows of strawberries, or more if desired. These could be planted in single rows between the gooseberries and currants. There would also be room for a few apples and plums. For cooking apples, plant Early Victoria (July) and Rev. W. Wilks (October). For dessert, James Grieve (September) and Cox's Orange Pippin. Golden Gage, a dessert plum ripe in August, would be worth growing, and for a second, I should try a Victoria.

Of course, more fruit trees can be grown if they are trained on the cordon or espalier system, but this means more work in pruning. Now is the time to order fruit trees for autumn delivery. Study a catalogue and enquire what varieties succeed best in your locality before ordering.

Worm Casts.

THE wet summer, rank vegetable growth, and falling leaves—these are the conditions which make worms plentiful in the soil, and on the lawn their activities are specially noticeable. Several large seedsmen supply special powders for destroying earth worms, and in the small garden these remedies are useful, as they are readily prepared and extremely effective. Lime is obnoxious to most earthworms, and a liberal dressing of freshly slaked lime has the effect of bringing them to the surface, when they can be swept up and buried in a deep hole elsewhere. The best method is to dissolve the lime in water and distribute the liquid with a rose water-can. In the flower garden or vegetable garden they are the gardener's friends. They feed upon dead vegetable matter, and worm casts actually enrich the soil. The burrows they make help the drainage of the soil, and enable more air to be admitted.

NOVEMBER in the TOWN GARDEN.

WHAT TO DO THIS MONTH.

1.—*Collect all old leaves and store for making leaf mould. They are worth their weight in gold.*

2.—*Plant roses in suburban gardens. In very smoky parts, defer planting until February or March. This advice applies to all trees and shrubs.*

3.—*Insert cuttings of currants, gooseberries and roses.*

4.—*All kinds of fruit trees and bushes may be planted in favourable weather.*

5.—*Tie up endive to blanch.*

6.—*Trench vacant land where necessary.*

7.—*Plant tulips in window boxes.*

8.—*Remove bulbs in bowls into the light, when top growth has commenced.*

9.—*This is the time to apply lime, kainit and basic slag when digging or forking is done.*

10.—*In wet weather, tidy up the garden shed, sharpen and clean tools, sponge the leaves of indoor foliage plants, wash the glass and stages of greenhouses, send for all the catalogues mentioned in* THE GARDEN *and study their inspiring pages.*

A Dripping Well.

DRIPPING wells in the garden are both useful and artistic. Water drawn direct from a tap is usually too cold for watering until it has been exposed to the air for some time. Dripping wells should, of course, be fitted with a ball tap to keep the water-level constant. Stone paths, such as are seen in the garden illustrated are more suitable near a dripping well than paths of gravel or grass.

A DRIPPING WELL FORMS A PLEASANT FEATURE IN A SMALL GARDEN.

Spring Preparations.

MOST plants have a rest time, or, at least, a time when normal growth ceases and, apparently, no activity is taking place. Scientists know, however, that this "rest" is not inaction, for frequently intense activity is taking place in the internal mechanism of a plant when, outwardly, all remains quiescent. It is the same with the gardener. Though he may not appear to do much during these shorter days of autumn and winter, he has really no time to rest, for even now the preparations for next season are in full swing.

Sweet Pea Trenches.

There is the question of sowing sweet peas. Whether the gardener intends to sow in springtime, or has already his seeds in pots or boxes under glass, now is the time to prepare the ground in which the plants are to grow. One famous grower advocates opening the trench now, leaving it exposed until Christmas and then filling it in. The actual planting would not, of course, be done until late February or March. The reason for digging deep trenches for sweet peas is so that there is plenty of depth of cultivated soil below the plants. The roots run deep, and they require, in addition to food supplies, a good supply of air. In soil only cultivated to a depth of a foot or so, the roots cannot remain healthy. By opening a trench now, the weather action breaks the lower layer of soil, allowing air and moisture to penetrate far more deeply than they would otherwise do.

How to Plant Holly.

SUPPOSE you have a holly bush to plant in a back corner of the flower border. The first thing to do is to dig a hole 3ft. in daimeter and 12ins. deep. Do not bring the bottom soil to the top, but break it up well with a fork. If you can mix some well decayed manure or vegetable refuse with this under layer, will be of great benefit to the plant. Place the holly in an upright position, and stake before filling in the hole. Sprinkle fine soil around the roots, and work this among the fibres with your fingers. Lightly tread this, and fill in the soil to the level of the surrounding surface.

It is usually possible to tell how deep to plant by the previous soil mark on the stem. If the weather is dry, give the soil a good soaking. This method of planting is suitable for all evergreen shrubs or hedges that are to be planted at this season.

Should the roots have been damaged considerably, it is advisable to cut away some of the top, choosing always the ill shaped and weakly shoots for removal, and bearing in mind the desired shape of the plant

THIS WEEK IN THE FLOWER GARDEN

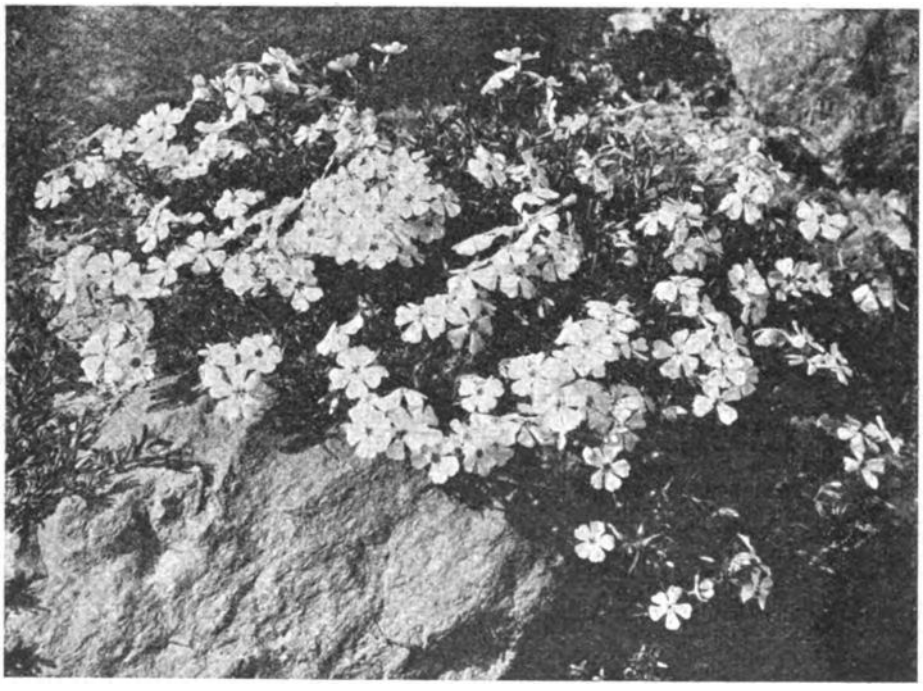
Work in the Herbaceous Border.

FROM observations kept earlier in the season those plants in the border which were not giving satisfaction ought now to be replanted, and it is advisable to change their position so as to give them the best chance to recuperate and make healthy plants for next year's flowering season. It is wise to prepare beforehand the selected manure by having it well rotted and in a fit state for application during the planting season. Varying composts, according to the requirements of each group or individual plant, can be mixed as the operation of planting proceeds, but their use in many cases is hardly necessary if good farmyard manure is given in liberal quantities. The plants singled out for shifting can be cut down to 1ft. from the ground, leaving as much old stem as enables them to be easily handled during their transfer. As many herbaceous plants have fibrous roots it is important to use a fork for lifting. The use of a spade at this particular time completely destroys those roots which are essential for the future well-being of the plant. Should the plant require reduction, and it is more than likely, as in the case of plants like Chrysanthemum maximum or Michaelmas daisy, the fork plays the important part. Separate the plant as far as possible with two forks placed back to back and pull the handles outwards. The centre part can now be thrown away and place the remaining pieces in the hole previously prepared with their outer edges towards the centre.

The young shoots will now be growing in the opposite direction and we rely on those to give the best flowers next summer.

It is most important that the hole should be made much larger than the plant, and sufficiently deep to contain a good supply of manure at the bottom for the retention of moisture, especially if the soil is of a sandy nature. By the addition of a little good compost on the top and well firmed by tramping, the plant is now ready for placing. Make sure that the roots are well spread out and at the proper depth, as shallow-rooting plants do not respond to being buried. Before adding the remainder of the soil it is important that the edge of the hole should be broken down with a fork, as during dry weather the plants suffer from drought through the old and new soil not being intermixed. This is more apparent in clayey soil and quite easily seen by the ring or crack which is formed round the plant. In planting, difficulty is often experienced in maintaining the right level in keeping with the rest of the border, and in an area where many plants have to be lifted it is better to remove all plants which can be lifted with safety, trench the whole and replant it. Nothing looks worse than to see the border like a switchback due to neglect of keeping an eye on the regular level.

Canterbury bells will require to be planted in their permanent quarters, and if carefully lifted with good balls of soil they will not be checked in growth. Being gross feeders, a liberal application of manure should be given. Delphiniums which have increased in size and given out for want of sufficient nourishment in the soil should receive attention. The operation of dividing them ought to be done with as much care as possible, using a large knife instead of chopping through the plant at random with a spade, so commonly practised. As this plant forms crowns containing many fleshy buds or shoots, division also by forks often destroys the buds, but by using the knife to cut between the parts containing them many good essential shoots will be spared for next year's flowering.—A. McC.



P. SUBULATA "SPRITE," A DAINTY AND FREE-FLOWERING DWARF PHLOX.

Stone-Edged Flower Borders.

Their Possibilities.

IN quite a number of gardens to-day one notices, instead of formal edging tiles, that rough pieces of stones, boulders and rock are used to form a division between the borders and paths. Some of these edgings are raised slightly from ground level, and thus opportunity is given for growing plants that show themselves to better advantage when in bloom than if planted close up to a tile in the orthodox way. One finds such gardens in country districts where, within proximity to stone quarries, it is not difficult to obtain small pieces, not suitable for the purpose of flagging paths, at a reasonable rate. I know of one such garden the owner of which planned and planted it, and the raised border in spring and early summer is a pleasure to see. It has been formed of pieces of sandstone, and time has softened and weathered them, so that now they give one the idea that they have occupied the ground for years. This stone-edged border has been planted with a variety of plants, chief among them being aubrietias, mossy saxifrages, compact-growing campanulas like pulla and G. F. Wilson and, armerias (thrifts).

Such a border opens up many possibilities for beauty. If it is on the cool side of the garden, one can plant some of the hardy primulas like Julie or Wanda, marginata or rosea, which grow but a few inches in height and give us freely of their blossoms. Many violas do well on the coolest side of the garden, from the old form of cornuta to the free-blooming graciis with purple-blue flowers. In the crevices of the stones one can plant in groups small bulbs; like scillas and crocuses, snowdrops or chionodoxas, which can be left for several years without needing much that will give joy to a lover of flowers for attention. No time is more opportune than the late autumn for making such edgings.—C.

A Free-Flowering Dwarf Phlox for the Rock Garden.

AMONG dwarf phloxes, P. subulata and its varieties are exceedingly free flowering. They form mats of green, studded in early summer with white, lilac, pink or mauve flowers, borne on stems of 4ins. to 6ins. in length. P. subulata is easy to grow, it should be given a sunny ledge in the rock garden. The illustration shows the bright rose variety Sprite, which has a crimson eye; other good varieties are Vivid, rosy carmine and G. F. Wilson, rich mauve. Any of these can be planted this autumn.—P.

A Handsome Bulbous Plant from the Cape.

Antholyza Paniculata.

DURING August and September this bulbous plant is an acquisition to the herbaceous border, and it will prove hardy in most districts, although it is occasionally referred to as a fit subject for the base of a south wall. It is a robust plant with bold blades of foliage and graceful branching scapes of crimson and yellow flowers, reminding one somewhat of the montbretias. When in bloom the whole plant is from 3ft. to 4ft. high, so should be given a position towards the back of the border, where its full beauty will be revealed. To get the finest results, the ground should be enriched with partly decayed manure or bone-meal before planting, and preference should be given to a position which is well drained.

The antholyzas may be planted from November to March, when the tubers are dormant. In a few years existing clumps will become overcrowded; then it is advisable to lift, divide and replant on a fresh site, which, of course, only need be a few feet away. Such work can be carried out when the border is dug over or renovated during the winter months. The variety major is a slight improvement on the type.—T. W. P.

Herbaceous Lobelias for Late Summer.

UNDER this heading will be found some of the brightest flowers that adorn our gardens during the late summer and autumn, and they will remain in full beauty till destroyed by frosts. In some catalogues the varieties or hybrids mentioned below will be found under the heading of Lobelia fulgens, but their origin, however, does not

Digitized by Google

concern us for the moment. One of the best is Huntsman, and when well grown the spikes will attain a height of 4ft. to 5ft. for even more. It is a strong-growing variety with large individual flowers of bright vermilion; the stems are purple and the leaves dark green, which is in striking contrast to the brilliant spikes. A few plants in the border make a most striking feature.

An old favourite is the form known as Queen Victoria with intense cardinal red flowers and dark purple foliage, and it is still worthy of a place in gardens to-day. Firefly is another handsome variety with vivid crimson-scarlet flowers. Both these plants vary in height from 2ft. to 3ft. Ibis is of more recent introduction with cerise-rose flowers and bronze foliage, and a characteristic feature of this plant is the distinct branching habit. It grows about 3ft. high. Another departure from the type regarding colour is Mrs. Humbert, which is a light salmon-pink and attains a height of about 2ft. No doubt in time we shall possess some real good pink shades, and till then I shall prefer the brilliant scarlets of which Huntsman and Firefly are about the best. Anyone having seen a bed or clump of these lobelias cannot fail to be impressed by their beauty and brilliance, especially during the autumn months, and seeing that they are of easy culture, not too particular regarding soil and reasonable in price, it is somewhat surprising that they are not more frequently met with in gardens.

Perhaps they have been regarded as hardy, and in many districts such is the case, especially if a layer of ashes is placed over the clumps during the winter months. I have had plants live outside for several years, but as a rule they pay for lifting, and may be placed in boxes with a little soil between the roots and kept in a frost-proof shed or frame. In the spring the plants can be divided into single crowns and then replanted in their summer quarters. In spite of continual rain these lobelias have made a bold display when other flowers present a woebegone appearance.—T. W.

A Choice Chinese Shrub.

FROM time to time during the last fifty years there has been introduced from China into this and other European countries a vast assortment of new plants—many of them good, others bad, and the residue being plants of indifferent merit.

In the front rank, however, must be placed the Itea ilicifolia, a handsome evergreen flowering shrub, one of the many happy discoveries of Professor Henry in Western China.

Its spinous artistically veined leaves, which resemble those of the holly but of finer texture, are somewhat oval in shape and of a bright, shiny green, 3ins. to 4ins. long, slightly less in width, and these with the reddish brown of the young foliage give the plant a fresh, clean and glossy appearance, very much as if it were in the habit of receiving a daily syringe.

It commences to flower in August, and continues well into the autumn to display its long, graceful, pendulous racemes, sometimes forking out into twos and threes, and varying in size from 6ins. up to a foot in length, of closely packed greenish white flowers, not unlike the mignonette, with fragrance strongly reminiscent of honey.

The shrub in the illustration seems happily disposed here in deep rich loam, with a south-south-east aspect, where, during the warmest part of the day, it happens to have the semi-shade of the Chilean evergreen, Maytenus Boaria, and is well sheltered from the south-westerly gales, for the shoots, being brittle, are likely to be broken by strong wind and, be it known, will certainly be damaged by rough or even careless handling in the border.

Subject to this precaution being taken, the Itea ilicifolia will add grace and dignity to any shrubbery in the milder and more equable districts of the British Isles, however select and aristocratic its denizens may be. In the colder parts the authorities recommend that it should be tried with the protection of a wall.

Propagation is not a difficult matter, as plants can with ease be raised from cuttings, layering, to which the lower branches readily lend themselves, and by means of rooted pieces from the base of the plant.—W. R. J., *Anglesea*.

ITEA ILICIFOLIA, A HANDSOME EVERGREEN SHRUB WHICH FLOURISHES IN MILD DISTRICTS.

ASTILBE SIMPLICIFOLIA, A GRACEFUL AND LATE-FLOWERING ROCK PLANT.

A Charming Rock Plant

Astilbe simplicifolia.

THIS little plant is in every respect a first-rate subject for the rock garden, for it is not only dwarf and orderly in habit, but singularly elegant, and it flowers throughout the later summer—that is, after most alpines are over. Astilbe simplicifolia is a native of Japan and it was introduced to this country quite by accident a few years ago, a root being found in an imported clump of schizocodon. It is a hardy perennial, making a neat little tuft of dark green, glossy, undivided leaves not more than 3ins. or 4ins. high. The blossoms, borne in graceful, air plumes of about double that height, are white and lace-like, and so delicate and profuse are the inflorescences that a plant in full bloom seems to sparkle and effervesce with crystal foam. All this delightful astilbe needs is a fairly moist corner of well drained soil enriched and kept cool with a little leaf-mould. It appears to enjoy shade from the midday sun and does not object to being screened by a neighbouring bush. Propagation is effected by seed or division, but one may often detach small offsets without disturbing the main plant. This may be done in autumn, but in gardens where difficulty has been experienced in establishing this plant, spring would be a safer season for such work. There is a very attractive variety of A. simplicifolia with rosy flowers, and a large number of pretty hybrids have been raised by crossing this species with A. Arendsii and others.—A. T. J.

Betonica in the Border.

THE betonica, otherwise stachys, with the exception of the woolly-leaved S. lanata (lamb's ear), often used as an edging plant, is very rarely seen in the border. Yet Betonica grandiflora, although not free from a suspicion of coarseness, is a decidedly handsome plant, is perfectly hardy and quite indifferent as to soil or aspect, except if the former is on the rich side it will considerably exceed its normal height of 2ft. The flowers, reddish purple in colour, are arranged in whorls on stout stalks, and are both decorative and lasting in a cut state. The colour of Betonica grandiflora superbum is rather brighter than that of the type, and B. rosea is a still better shade, but it is only 1½ft. high and is not such a strong grower as B. grandiflora. B. coccinea has flowers that are nearly scarlet, but it is not more than 1ft. in height and is not quite hardy except in a warm and sheltered position. If these conditions can be provided, it is well worth growing. B. nivea, which is a comparatively recent introduction from the Caucasus, has spikes of creamy white flowers, and is 1½ft. tall. It is effective in the border if grown in a good-sized clump, but is perhaps seen at its best in the rock garden.—R. E. H.

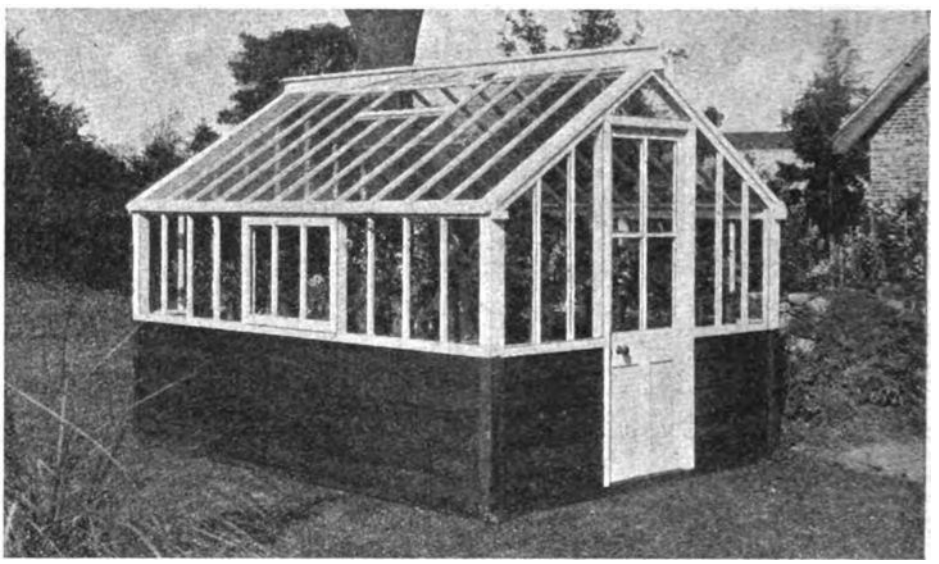
THE AMATEUR'S GREENHOUSE

Points to consider when purchasing or erecting a small greenhouse. There is no more useful asset to a small garden than a greenhouse and where possible amateurs should decide to erect one this winter.

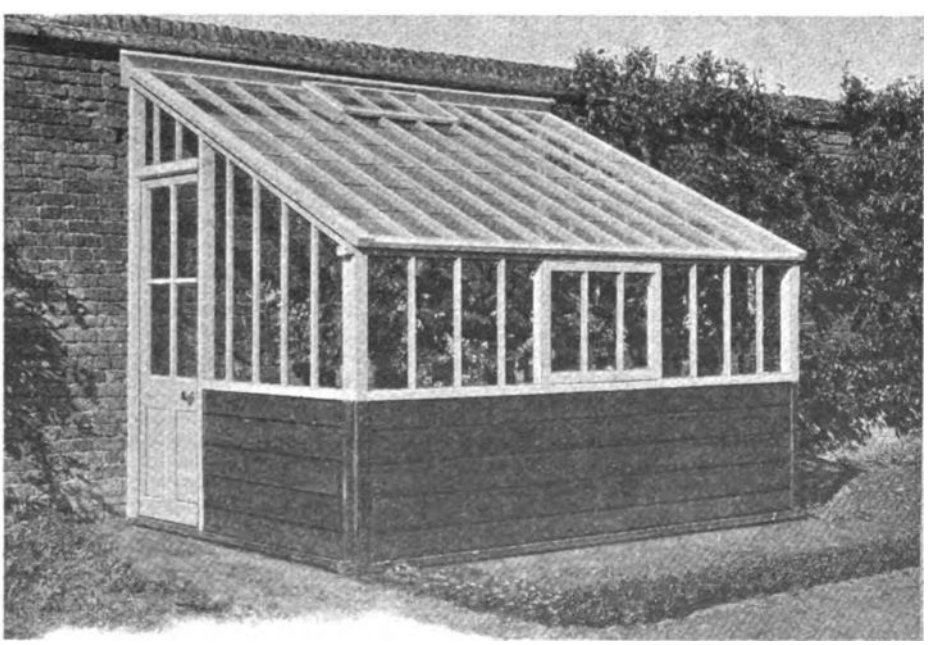
IT has been frequently quoted that "he who loves a garden loves a greenhouse, too," and there is a lot of truth in the statement, in spite of the fact that these structures have been referred to somewhat disparagingly by many, especially since 1918. When considering the purchase of a small greenhouse, the first thing to do is select the site, and in doing this remember that sunlight is an essential factor. The greenhouse, therefore, ought not to be overshadowed by trees, and where possible it should face south, if of a lean-to type, and run from north to south if span-roofed. These may be termed the ideal positions, but excellent results can be obtained from almost any aspect, except north, and a greenhouse on the cold side of a building can hardly be considered a success, except, perhaps, for ferns, and even then it would be very cold in winter. Before commencing operations the owner must decide whether the greenhouse shall be a permanent or tenant's fixture. For those who do not own the property, the latter should be chosen, unless some arrangements suitable to both the landlord and tenant can be made. With others who own their dwelling house and immediate surroundings, a more permanent structure with a brick or concrete base is recommended.



A SMALL SPAN ROOF GREENHOUSE WHICH EVERY AMATEUR WILL FIND OF EXTREME SERVICE.

It may be placed in any position in the garden provided it gets sunshine.

To-day there are a variety of greenhouses to choose from, and in the illustration is a span roof greenhouse which is suitable for erection on leasehold property. It is made in such a way that the structure can easily be removed if the necessity arises. It is constructed of well seasoned deal, provided with ample ventilation, two side stages and glazed with 21oz. glass. This house can be obtained in various sizes, and the medium one is 15ft. in length, 9ft. wide, 8ft. 6ins. high, and height to eaves 5ft. Where there is a sunny wall facing south, south-east or south-west, the lean-to type of greenhouse will be found useful. It is made of selected red deal, glazed with 21oz. glass, and every 10ft. length is fitted with a top and front ventilator. The height at the back is 8ft. 6ins., and from floor to eaves, 4ft. 9ins. It is 7ft. wide and the length varies from 10ft. to 20ft., but if required, a longer house can be supplied. These are the two principal designs, but there are others, such as three-quarter span, and different shapes, one made especially to fit in with other existing buildings, but for durability, and cheapness, the standard designs are strongly recommended. When it is decided to build a greenhouse or even buy a frame, always consult a horticultural builder, such as advertise in THE GARDEN, and never allow the local tradesman to do the work. Very few of the latter understand what a greenhouse is really for, and much too heavy timber is usually employed; and I write from experience. Moreover, when the structure is erected, keep it painted, and only use the best quality white paint. The outside will need a coat every third year, and the inside each fourth or fifth season. Broken glass should be repaired at once, and if these details are given attention, the life of the greenhouse is considerably prolonged. The guttering ought also to be kept clean, and wherever possible a tank set at one end of the house to supply soft water for watering purposes. Greenhouses are now obtainable made entirely of steel, except the doors, which are made of thoroughly well-seasoned red deal. They are put together with bolts, nuts and screws and are thus easily erected. They can be arranged either on a brick or wooden base. The cost works out about the same as for a good class wooden house. They are obtainable in various sizes and in different types, and the amateur will readily find one suitable to his requirements. They are durable and economical in upkeep since they are not subject to outside influences such as heat and moisture, as are many wooden houses of a cheap nature.



A SMALL TENANT'S FIXTURE GREENHOUSE, SUITABLE FOR ERECTING AGAINST A SUNNY SOUTH WALL.

It is an ideal house for use in a small garden where there is a brick or stone wall.

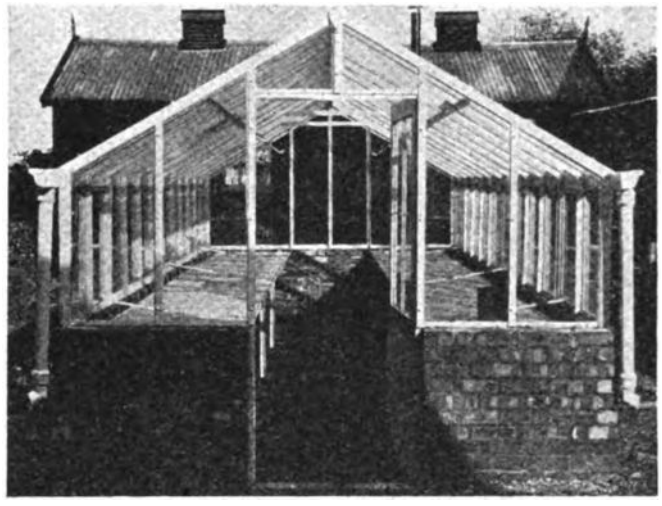
Now comes the question of heating; if the greenhouse can be kept about 40 degrees Fahr. during cold weather, it naturally follows that a greater variety of plants can be grown therein. This, however, concerns the owner and his pocket, but once the heating apparatus is installed the cost of fuel would be fairly low, especially if cinders and small coal is carefully set aside from the dwelling house. Occasionally the local coal merchant has a ton or so of small coal to dispose of quite reasonable in price. There should be two rows of four-inch piping, the joints being made with india rubber rings, and suitable good makes of boilers of various sizes can be obtained from advertisers in this journal. Make sure that boiler power is ample, and in this respect it would be best to be guided by the greenhouse builders. The approximate cost would be between seven and eight pounds for such greenhouses as described above. On the other hand, a lot of pleasure can be obtained from a non-heated greenhouse, and in proof of this statement, I may

Digitized by Google

say that a neighbour of mine (a tradesman and keen amateur gardener) produces fine prize-winning begonias from a lean-to house approximately 10ft. long and 7ft. wide, and starts tubers into growth for his flower beds. Another specialises in roses, and secures a wealth of bloom a few weeks in advance of those outside. So it will be quite obvious to the keen amateur that there are great possibilities even if no heat is provided.

For most plants a little shade is beneficial during the hot summer months, and if expense must be cut down to a minimum, then summer cloud or a similar substance must be painted on the outside glass. A better plan, however, is a roller blind made of thin canvas, while wood lath blinds are neat, but more expensive at the beginning. The latter, however, can be left on the house throughout the year and, moreover, they will be found an aid in reducing the fuel bill if run down on cold, frosty nights.

A lattice wood staging is usually provided, but it has been proved that plants thrive better on a closed stage, so a few builders' slates should be laid over the lattice wood,



A GREENHOUSE WITH AN ALL-STEEL FRAMEWORK BUILT ON A BRICK FOUNDATION. NOTE THE WIDE STAGING.

and then covered with sifted ashes or fine gravel, on which the plants stand. The amateur often throws away good money on the path, and one often sees ornamental tiles and such like laid down along the gangway. Concrete is often employed, but these three types of path should be avoided. Much cheaper material can be found, such as ashes, or gravel, and the plants will appreciate the better atmospheric conditions caused by the natural rising of moisture from the earth. Moreover, it has a tendency to keep down such pests as red spider.

This is a brief article on the main or principal features concerning the construction of a small greenhouse for the amateur, and I may say that much of the matter also applies to larger structures.

When building a greenhouse it will pay to advise a reliable firm, because there may be, and is, cheaper materials on the market, but the lasting qualities cannot be compared to the goods supplied by a firm who has a good reputation to maintain. T. W. B.

WHAT OUR READERS SAY

HOW I MADE A ROCK GARDEN.

SIR,—There was a long narrow strip of ground behind my house which had been used by its former owner as a convenient dumping-ground for rubbish of all kinds. The idea of turning it into a rock garden had a great attraction for me, but I had no idea how to set about it. All through the winter I took THE GARDEN, and each week I cut out every article or note on rock gardening and every photograph of rock gardens, mounting them in a big scrap-book and studying them carefully in my leisure moments.

In February and March I made my garden from my scrap-book knowledge. It proved a most excellent guide, enabling me to avoid the mistakes amateur rock gardeners almost invariably make. My rocks were not laid on the surface or set bolt upright; my plants were firmly planted; each kind had its right soil and aspect, and I included a delightful moraine. The enclosed photograph shows the result a few months afterwards. When I wanted to make a water garden with a lily pool I adopted the same preliminary plan, with equal success. —G. H.

WINTERING ECHEVERIAS.

SIR,—I note in your "Hints Worth Remembering" (page 705) "E. B.'s" interesting method of keeping echeverias through the winter, to which I beg to add my own practice. In the old days of carpet bedding, when echeverias were employed in immense numbers for tracing, edgings, etc., it was a serious problem how to winter the plants, especially where glasshouses in plenty were not available, so many makeshifts had to be resorted to, among which were the following:

First of all, an unfurnished south wall was selected and any light soil dumped against it; then the plants—cleaned of side shoots and decaying matter—were built up on the face of it, tier by tier, and almost perpendicular, reinforced with short pieces of old peasticks to prevent the whole mass slipping down with the weight. When thus built up to the desired height, boards were laid on the top of the soil and overhanging far enough to prevent the drip dropping on the plants of the lower rows.

As our stock increased wall room became less available for our requirements, so we were compelled to make other provisions, which, happily, turned out quite satisfactory.

A plot in the vegetable garden with a southerly aspect was "commandeered," piles driven in at short distances apart, twiggy branches worked in and out (wattled) between, thus forming substitutes for walls, proceeding with the soil and plants in every detail as in the case of the walls.

A SMALL BUT CHARMING ROCK GARDEN ONLY SOME SIX MONTHS AFTER MAKING.

During the winter they needed but little attention, the main points being to keep them perfectly dry, looking over them occasionally to pick off decaying leaves, and during severe frost hang a few mats along the front of the ridges. Thus exposed to light and air we have repeatedly and successfully wintered scores of thousands of echeverias without practically any loss and without any glass, loose or otherwise. I can confidently recommend this system.—J. R., *Merioneth, North Wales.*

MEALY BUG ON VINES.

SIR,—Having read "F. D.'s" remarks on page 710 of THE GARDEN on mealy bug, perhaps it would be of some interest to tell him of my experience. I have had vines infested badly; in fact, I saw a vinery last season and the rods were almost white with mealy bug. I recommended a remedy which appeared in THE GARDEN and have practised myself for two years with great success. Instead of painting the rods with a mixture of clay, tobacco and sulphur, I paint them with painters' knotting all over, buds and all. These will push through all right in spring. This knotting forms a glaze on the rod resembling varnish and sets hard, starving any insects underneath; not only that, any stray insects that are about in the spring can easily be seen on the shining rod. A sharp look-out in spring and early summer, with a brush of methylated spirit, is the most important part. Should time permit this being done, soak some cotton wool in the spirit and tie above each bunch, which will prevent the insects entering the bunches. This season several gardeners of my acquaintance have practised this method and have been very grateful for doing so. I, for one, have been able to keep the bunches clear and shall continue with the same method this winter.—F. W. D., *Leamington Spa.*

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

THE recognised practice of propagating summer and autumn flowering chrysanthemums consists of raising new stocks by means of cuttings taken in February and March, a process that is fully justified by its simplicity and success. It may therefore interest, and probably surprise, many readers of THE GARDEN to learn that the popular perennial species can be treated as an annual, inasmuch as the plants may be raised from seed sown in spring and flowered in the same season. At the last monthly meeting of the Glasgow and West of Scotland Horticultural Society, Mr. Alexander McAlpine, Tollcross, brought a collection of nineteen sorts of chrysanthemum blooms which were produced on plants grown from seed this year.

When should liliums be planted? That point was raised by a correspondent who had searched numerous catalogues and garden books in vain. Several of the latter publications specified the period of flowering, but all the writers had overlooked the importance of planting to the amateur grower. As a personal search through innumerable pages of garden literature confirmed the above statement, a little light on the subject may be opportune. All the hardy types of liliums may be safely planted in the open ground at this season, but if the soil is heavy it should be lightened by incorporating leaf-soil and sand in liberal measure, and as a further precaution against decay it is advisable to surround the bulbs with sand at the time of planting. Supplies of the favourite Lilium auratum are seldom available before January, and they are therefore planted in spring at the same time as the less hardy species. For glasshouse culture it is usual to pot up the bulbs at this season in a compost consisting of three parts leaf-soil, one part old rotted manure with a sprinkling of sand added.

As garden operations are frequently suspended for an indefinite period in winter owing to the severity of the weather, my advice to growers of sweet peas is to take advantage of the first favourable spell and begin the preparation of the soil. Take out a trench 2½ft. to 3ft. deep and heap up the soil roughly on either side. The width depends on the number of rows that are to be grown. If there is only to be a single line, a breadth of 2ft. is ample for the purpose, but that space must be extended another foot if the plants are to be arranged in a double line. When the work of excavation is completed fork over the bottom of the trench, which will have the effect of breaking up the solid ground to a further depth of about 9ins. Allow it to lie in that condition for a week or two and make use of the interval by collecting and burning all the available garden refuse, the residue of which should then be incorporated with the best farmyard manure that can be obtained. The further treatment varies according to the method of filling up the trench. Some growers favour the sandwich principle, which consists of alternate layers of manure and soil, but as the roots of the plants are in danger of getting burned when they penetrate into solid manure, I prefer the alternative system of mixing soil and manure together, an operation that is easier accomplished on the surface than in the trench. Begin by scattering ground bones freely over the bottom and afterwards fill up the trench to within 9ins. of the ground level with the prepared compost supplemented by a liberal dressing of bone-meal, wood ashes and basic slag. No animal manure is needed in the upper soil, which may be subjected to different forms of treatment. Slow-acting manures, such as basic slag and bone-meal, are suitable, but there are expert growers who believe in a dressing of sulphate of potash, all of which are washed in by the rains before the trench is ready for planting in April. In either case the filling in of the trench should be completed before the end of the year, and an occasional dusting of soot during winter contributes to the beneficial properties of the soil.

Brussels sprouts are generally appreciated as a winter vegetable, but as a result of the wet weather experienced throughout the summer and up till the end of September growth has not been satisfactory. It is not uncommon in allotment and garden crops to find that the buttons have not set closely or that they are slow in forming the firm specimens that are desired. As an aid to maturity remove the bottom leaves, some of which are beginning to wither, and give the plants a light top-dressing of a fertiliser such as Clay's at intervals of a week. When the sprouts are round and firm with not a leaf unfolded they should be gathered in a systematic manner by picking the bottom ones first and leaving those at the top, which are protected by the leaves, to the last. Liquid manure with alternate applications of nitrate of soda may be given as an alternative treatment when the soil is not in a sodden condition.

Good and early results may be obtained by planting a few crowns of Early Victoria rhubarb in the soil that was occupied by tomatoes, but if the ground is not available a good-sized box that will accommodate a root planted in soil taken from the tomato bed will serve the same purpose. Place the boxes on the floor of the greenhouse and provide water two or three times a week. Rhubarb cultivated in this manner should be ready for pulling in February.

It is not too late to take cuttings of gooseberries, which are easily struck in the open ground. Select shoots of medium strength of this season's growth; cut them about 9ins. long and strip off all the buds with the exception of three or four at the upper end. Insert the cuttings in a trench 5ins. or 6ins. deep and sprinkle a layer of fine soil in the bottom before filling it in, taking care that the earth round each cutting is made firm.

The chief advantages obtained by the observance of crop rotation in the vegetable garden are threefold. In the first place, the application of its principles is economical in the use of manure; secondly, it promotes maximum production of the highest possible quality; and last, but not least, it checks the activities of insect pests in the soil and prevents the spread of fungoid diseases.

ST. MUNGO.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT

Sowing Broad Beans for Early Use.

It is now time to make a sowing of broad beans. Now I find a good way to have a batch early and winter them safely is to dig a trench a foot wide and 18ins. deep. Place well rotted manure in the bottom, then a layer of soil, on the top of this a layer of last autumn's leaves, beech for preference. Now fill up to within 6ins. of the top with a mixture of soil, soot and wood ashes. Sow the seed on this and cover with 3ins. of soil—that leaves 3ins. to the top of the trench. This affords protection to the young plants as they appear, and in a severe time extra protection can be given by placing sheets of glass or even canvas over the top of the trench. I had beautiful beans for exhibition the first week in July this year.—J. H.

Goldfish in the Lily Pool.

The brilliant colouring of goldfish makes them a delightful addition to a water lily pond, especially when the leaves of the lilies are in their red or olive stages of colour. It is almost useless, however, to place in the pool the goldfish usually sold in glass bowls. They are natives of Japan and will not survive an English winter out of doors, although they may, of course, be caught and transferred to a greenhouse tank when the weather gets cold.

English-bred goldfish are perfectly hardy, only needing to have the ice broken in very frosty weather to ensure sufficient air. For the same reason the surface of the pool should be watered with a large can when there is a long dry spell in summer. Goldfish usually cater for themselves, but in summer they appreciate occasional breadcrumbs and ants' eggs, which they can easily be taught to take from the hand.—G. H.

Seedlings of Meconopsis Wallichii.

Meconopsis Wallichii, the tall blue Himalayan poppy, is so beautiful that any gardener who has seen a good specimen in flower can never rest contented until he has made a determined effort to flower it in his own garden. This meconopsis, like other members of the family, comes readily from seed, but is by no means easy to grow on successfully to maturity. Many adventurers must now have seedlings of this poppy from a spring sowing, and some will be wondering how they are going to stand the winter. The following hints may be of value: Choose a site sheltered and shaded by shrubs; make the drainage sufficient beneath a compost at least 18ins. deep, made up of coarse grit, leaf-mould and peat; top-dress the seedlings with leaf-soil before frosts set in, being careful not to smother the crowns of the plants.—S. H. H.

Training Loganberries.

As your readers will now be busy transplanting such things as loganberries, I think the following hint may be useful, in that it prevents the new growth—which comes simultaneously with the ripening of the fruit—from being in the way either when gathering fruit or later on, when cutting out the old fruited wood. I have just transplanted my loganberries and, having plenty of room at my disposal, left some 8ft. to 10ft. between each plant. Then I trained all the canes in one direction and when the new growth reaches a trainable length next summer I shall train all these in an opposite direction, thus leaving the fruit-bearing canes all free. Another plan is to alternate, say, one right and the next left, leaving space between for new growth from both plants to be trained away from the fruiting canes.—C. J. B. S.

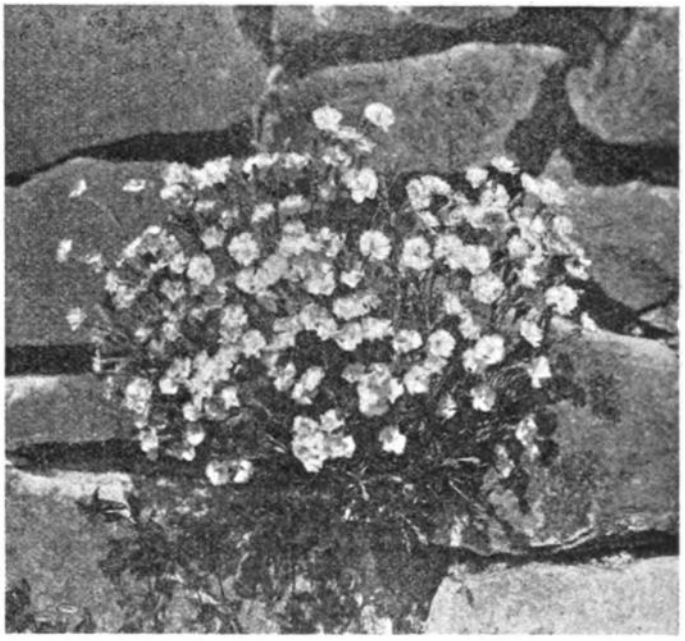
NURSERIES OF THE BRITISH ISLES.—XI

MESSRS. ALLWOOD BROTHERS, OF HAYWARD'S HEATH.

THE firm of Messrs. Allwood Brothers are proud of their carnation farm, and justly so, for it is one of the largest and most flourishing in the country, and has been built up by the sheer hard work and skill of three brothers who started in 1910 with little capital but much ambition. At this date these three brothers had had wide experience in horticulture, and understood every branch of the carnation business. They rented at first four small greenhouses, and the work was carried on under the direction of Mr. Montagu and Mr. Edward Allwood. It was not until Mr. George Allwood came back from America with stocks of the best American carnations that the Wivelsfield Nurseries were started. During the initial stages of the growth of the firm, perpetual-flowering carnations were mainly grown, and the firm depended for revenue principally upon cut blooms which they sold in Covent Garden Market. Every penny that could be spared was devoted to raising seedlings and developing new races of carnations, such as Allwoodii, a race which at the present time has a world-wide fame. The first carnation which Messrs. Allwood sent out was Wivelsfield Wonder, a large white variety flaked with pink. It was introduced after the firm had been in business for three years. The following year Mary Allwood and Wivelsfield White were put on the market, and for the former variety an offer of £2,000 was wisely refused, for the demand for this cherry salmon carnation proved to be phenomenal, and at the time of the outbreak of the war Messrs. Allwood still had not a sufficient stock to cope with the demand. As was the case with many other horticultural firms, the war well-nigh ruined the firm of Messrs. Allwood Brothers. The best of their stocks were sent to an old friend of the firm's in Hampshire, and he took care of them until the war ended, and in their glass-houses tomatoes were grown by girls. As soon as conditions became normal, Messrs. Allwood started once more to build up their carnation business. They bought up all the best carnation stock of the various types that they were low in, and from that time the business of the firm has increased annually, until to-day, at the Wivelsfield and Clayton Nurseries, Messrs. Allwood Brothers possess eight acres of glass and employ nearly 200 people. Their carnations go to all parts of the world; in fact, they often do more business abroad than in the British Isles. They have raised some of the finest of our perpetual-flowering carnations, and we are indebted to them for some valuable new races, such as the Allwoodii, the perpetual border carnation and, during this last season, for a new race of hardy rock plants, Allwoodii alpinus. All these are the result of many years' work and untiring energy, for the raising of new carnations is a slow procedure; it needs care, skill and patience. Often out of a batch of thousands of seedlings only a few prove of any real value, and the raiser of new carnations is frequently doomed to disappointment; and yet the work is fascinating, and the anticipation that perhaps something really good may be discovered spurs the hybridist on.

The Wivelsfield Nurseries are in a delightful situation, some two and a half miles from Hayward's Heath. The soil is heavy clay, and the position an open and sunny one. All perpetual-flowering carnations are grown under glass, in large span-roofed houses of many feet in length; while in the outside borders, Allwoodii, perpetual border carnations, border carnations, Allwoodii alpinus and seedlings of the various types are cultivated. The carnations in the open are all grown in raised beds, which have been well drained and deeply dug. Lime is given to the soil, and shallow planting is always practised, for Messrs. Allwood are fully convinced that deep planting and lack of drainage are the chief causes of failure, particularly with border carnations.



ALLWOODII ALPINUS, A NEW RACE OF HARDY AND PERPETUAL FLOWERING ROCK PINKS.

CARNATIONS GROWN FOR SEED AT WIVELSFIELD NURSERIES.

When we visited the nursery the Allwoodii pinks were making a fine show. The firm has been working on this hardy race of pinks for fourteen years, and still they are introducing new varieties and new colours, and seeking to improve those that are already in existence. They are always aiming at producing short, compact, erect habit and plants that are truly perpetual-blooming from early spring and throughout the entire summer, and progress is still being made. Crimsons, reds and whites are being developed, and next year will see the introduction of several new varieties of this valuable race of plants which are so well adapted for border edgings or for the rockery in the amateur's garden, as they are hardy, robust, free-flowering and easy to cultivate and, above all, deliciously fragrant.

The most interesting collection of plants in the borders outside were the seedling Allwoodii alpinus. This race promises to have a great future, and we feel sure it will gain wide popularity. It has been raised by crossing seedling Allwoodii with various species of dianthus, and it has taken many years to produce the six varieties that have just been put on the market. Many crosses have been made and countless thousands of seedlings have been grown. Those seedlings have been selected and re-selected, until now a hardy plant with a short stocky habit,

Digitized by Google

dainty flowers borne on stems not more than 4ins. or 5ins. in length, has been obtained—an ideal plant for sunny rockeries, stone walls or buttresses. All these Allwoodii alpinus are named after the fairies: Puck has a small white flower with a deep maroon eye, and Tinkerbell is a pretty pale pink shaded towards the centre.

After looking at the carnations outside, we then turned our attention to those in the houses, and here there was much to see. The houses were all well ventilated and with the exception of the propagating house were all large and lofty. Some were devoted to the growing of carnations for cut flowers, others to the growing of plants solely for propagating purposes; some were filled with young plants, others with carnations which were being used for hybridisation work. All Messrs. Allwood's perpetual carnations are grown on and planted out in beds (or benches, as they are frequently called), for the attention they require in the matter of feeding and watering is much less. The plants were in good, healthy condition, for Messrs. Allwood are able to keep every pest and disease, such as red spider, rust and mildew, in check, as they have found a remedy and control measure for each. By proper feeding and constant re-selection they never allow their stocks to deteriorate, and so their plants are of good constitution, and therefore better able to resist disease. The plants were trained between wires and grown quite naturally.

Messrs. Allwood fully realise the great importance of propagating only from plants of good constitution, good colour, and those which produce abundant crops at all seasons, and are not liable to split their calyx. They never propagate from exhausted or worn-out stock, and they are careful to select from healthy, disease-free plants only the best and most suitable cuttings and those of even size. The plants which this firm send out are, consequently, robust and healthy to start with.

Although most carnation growers prefer to propagate during December, January or February, Messrs. Allwood propagate during every month of the year. This is because many of the young plants are sent abroad, and in order that they shall arrive at their destination at the right season of the year propagation must be carried on all the year round. It was June when we paid our visit, and even in this month there were many workers busy taking cuttings. These cuttings were being inserted in sand in pans, and then placed in propagating cases in the special propagating houses which were provided with double shading. Messrs. Allwood's success in propagation depends to a great extent on cleanliness and orderliness; they use clean Thames sand and maintain a buoyant atmosphere by judicious ventilation night and day. Their carnations never receive any check, they are not allowed to suffer from lack of water, nor are they overfed. They are always kept growing. They are given mild, slow acting food, a food which is well balanced and one which exactly suits the requirements of the carnation. For many years Messrs. Allwood have been experimenting with carnation fertilisers, and they have now produced a food which gives highly satisfactory results.

Some of the rooted cuttings are despatched abroad by air mail, others are potted on in small pots, to be sold or used for the firm's own purposes. When the young plants themselves are exported they are securely packed in boxes and kept in cold storage while on the voyage.

Messrs. Allwood pay considerable attention to the raising of new perpetual carnations as well as to the raising of new races. Innumerable crosses are made each year, and thousands of seedlings are grown on. Seedlings which do not come up to expectations, either in scent, colour, form or substance, are at once discarded, and also carnations which do not prove productive at all seasons of the year are not kept either. Strict account is kept of all crosses, and each cross is carefully marked. A large and representative collection of modern perpetual-flowering carnations were noted, and in good form were Beauty of Durham, a bright salmon pink; Master Michael Stoop, glowing cerise; Spectrum, a new vivid scarlet variety; Velvet, crimson and maroon; Shot Silk (a variety which is becoming very popular) and Coral Glow, terra-cotta tinged with bronze. There were many other fine varieties, far too numerous to mention.

In two large houses border carnations were being grown for exhibition work, and in another there was a very fine selection of perpetual border carnations. This latter type belongs to a valuable class of hybrids which is perpetual-flowering, bear blooms with the colours and old clove scent of the border carnation, and yet are perfectly hardy and compact in habit. Sussex Pink, Sussex Morn, Sussex Lady, Sussex Crimson, Sussex Beauty and Sussex Flake were a few of their best varieties. Their border carnations were particularly good in form and substance, and all of them had that strong, erect habit and glaucous blue foliage, qualities which all perfect border carnations should possess. The method which was being used for layering border carnations was interesting and not commonly practised. When making the tongue, instead of cutting upwards, Messrs. Allwood's employees are instructed to thrust the point of the knife through the layer and cut downwards and then neatly trim the tongue immediately under the joint. The parent plants were pot-grown, five or six layers were pegged down round the edge of each pot. Grenadier, one of the best red border carnations, was flowering well, so also was Bookham Flame, Jean Douglas, J. J. Keen, Loyalty, Border Mauve and Bindle, a white heavily flaked maroon.

Messrs. Allwood send out an enormous quantity of carnation seed to all parts of the world, and they do a large trade in their special carnation fertilisers, fungicides and insecticides, and wire carnation supports. A side-line which is developing rapidly is the production of carnation perfume, compressed blossoms and *pot-pourri*; in fact, every branch of the firm of Messrs. Allwood Brothers is developing, and one can look forward during coming years to many more fine introductions to the carnation world by this famous carnation firm, which has rendered such valuable service to horticulture and done so much to raise the carnation to the proud position which it holds to-day.

FRUIT AND KITCHEN GARDEN

Fruit Trees and Soil.

APPLES.—These succeed best in a deeply worked and well manured loamy soil, but good results are also obtained in a light soil that has been properly dug and well enriched. In the case of a very heavy soil it is essential that this should be deeply trenched. In addition it should be given a good dressing of manure and about half a bushel of lime or chalk to the square pole or rod, this application being thoroughly dug in.

Apricots.—Here a good loamy soil is the best to which has been added a little extra chalk, lime or mortar rubble, as well as some well decayed manure.

Cherries.—A good mellow loam with lime in it is preferred. Proof of this is found in the way cherries flourish in some of the chalky districts of Kent and Oxfordshire. Free drainage is of very great importance in the case of this fruit, as stagnant moisture in the ground is fatal to a healthy growth.

Currants.—Both red and white currants succeed best in a deep, well drained soil, and if this condition can be secured the bushes often do well on land that is not particularly rich. Anything like water-logged ground is very harmful. In the case of black currants a cool, retentive loam in rather a moist situation is the best. The fact that black currants like plenty of moisture is evidenced by the luxuriant way in which they grow in low situations and by pools and streams.

Gooseberries.—Here a fairly deep and fertile loam of medium consistency is the best. Free drainage is an important feature with gooseberries.

Grapes.—If certain varieties are chosen and a south wall is available, it is worth while attempting the culture of grapes out of doors. The most suitable varieties are Black Chester, black; Garnay Noir, black; Reine Olga, yellow; Sweet Water, pale yellow. Deeply trenched and well manured soil of a loamy nature is by far the best.

Loganberries, etc.—Loganberries and allied fruits flourish best in a moist loam.

Medlars.—Nowadays these are more valued as ornamental flowering trees than for their fruits, although at times they are planted in the orchard. The best results are secured when the tree is growing in a loamy soil.

Mulberries.—Mulberry trees are often grown as ornamental subjects, but they grow well against a wall facing south. Almost any good garden soil is suitable, but it should be of some depth and not too dry.

Peaches and Nectarines.—Here a rich loamy soil containing plenty of humus and a fair amount of lime or mortar rubble with it is needed. The soil must be deeply trenched before planting is carried out.

Pears.—The pear likes a rich loamy soil with a fair amount of sand or grit in it. On the whole the land on which pears will grow well may be a good deal lighter than that which is required for apples.

Plums, etc.—Plums are fastidious in their likes and dislikes, and the grower should find out the varieties which succeed best in his district and give the preference to these. A few kinds, such as Victoria, will grow well almost anywhere. A very rich soil is not so desirable, as this will tend to encourage the production of wood instead of fruit. A strong retentive loam is the best, but lime in some form or another is essential. Free drainage is of great importance.

Quince.—If space permits room should be found for a quince tree, as the fruit is very desirable for preserving, jelly making, etc. The most suitable soil is a warm, sandy loam where there is a free drainage.

Raspberries.—The raspberry likes a deep rich loam inclining to be heavy. As the plants are gross feeders, the ground should be deeply dug and enriched with manure.

Strawberries.—In a general way strawberries will grow in almost any good soil, but some of the varieties show strong likes and dislikes. When making a bed it is well to find out the requirements of the particular variety which is being planted. A good average soil is loam which has been deeply worked and well enriched with manure. No kinds of strawberries do really well on a soil that is either too heavy or too light.—L. B.

Planting Grape Vines.

NO longer is it considered necessary to bury a dead sheep at the root of every new vine in order that it may grow for many years and fruit successfully. A young vine is planted in a perfectly rational manner, carefully of course, and with the fact in view that it will remain undisturbed for years. First of all dig out to a good depth a hole very much larger than the young vine seems to need, either inside or outside the greenhouse. If drainage is not efficient, naturally go deeper than usual and fill the whole to the depth of a foot with stones and rubble. On this, or in the bottom of the hole, place a layer of fresh or old turf, grass side down. Now use the soil which has been dug out of the hole provided it is in good heart, or, best of all, get a supply of turf which has been stacked the better part of a year or more. Chop it up roughly. To this soil add plenty of old mortar or well weathered lime or ground chalk (carbonate). The correct amount is difficult to state, but it should be round about ½ stone per barrow-load. Also add half that of bonfire rubbish, consisting partly of fine ash and charcoal, and again some two to three pounds of good coarse bone meal. Sand may also be necessary, and perhaps some well rotted leaf-mould where the soil is stiff and retentive. Mix all the ingredients together and turn the heap over two or three times to get the whole blended into a good mixture; keep it, when being prepared, under cover. The young vines will arrive in or ex-pots. Remove them from the pot, shake away the soil and plant the shrubs practically at the same depth; this means filling in the hole partly with compost, tramped firm, first. Spread the roots evenly over the firm compost and cover with more compost; tread carefully round each shrub and level up with a mixture of fine soil, sand and sifted mould.—LANARKSHIRE.

Planting a Peach and a Nectarine Tree Under Glass.

IN hundreds of gardens there is only room for one peach or nectarine tree in a glass structure. Even one tree will afford a lot of interest to the cultivator. It is not necessary to have any artificial heating for the benefit of these fruits; but if the structure is already heated, then, of course, the trees may be forced a little and ripe fruits obtained at an early date. The back wall of a lean-to greenhouse facing due south is an ideal position for these trees. But if the house is span-roofed, the side facing east or south-east is the one best suited to peaches and nectarines.

Making the border is a very important work. The tree remains in the border for many years usually, and the roots should be in a good firm medium. One tree will require a border containing a square yard of soil, that is, specially prepared compost. Fibrous turves cut and stored for a period of six months are suitable, and such should be reduced to lumps about 4ins. square. Builders' mortar rubble mixed with the chopped turves at the rate of one bushel to six of the latter will be all that is necessary. Do not add any manure at this stage except a 6in. potful of finely ground bones to two bushels of compost. Lay whole turves on 6ins. of broken bricks to form a sound drainage. Use the compost while it is fairly dry, then it can be firmed a little by treading. Cover the roots with about 3ins. of soil, but do not bury any portion of the stem of the tree. Planting in November is an ideal time; the tying of the shoots to supporting wires should be left until the tree has settled down—usually by the early part of March. As regards varieties, I prefer Royal George peach and Humboldt Nectarine. The variety Royal George does not drop its buds if the soil is watered judiciously. The next best peach would be Peregrine. When the weather is open, admit air to newly planted trees throughout the winter months.—G. G.

New Beds of Asparagus.

ALTHOUGH, as a rule, asparagus borders are not planted out until spring, the border intended for this vegetable may be prepared beforehand with appreciable future benefits. It is well to remember, first of all, that asparagus "lies down" for a generation undisturbed, and so, although it may take a lot of time, the initial preparations are a measure of future success. Drain the plot if it needs it by running a field drain down the centre at 2½ft. in depth. After this has been done trench the soil to 2ft., but do not bring up the comparatively barren subsoil. Keep it where it is, but add to it coarse garden refuse, freshly fallen leaves, etc., and when the soil is heavy, a dressing of lime. The surface spit should be made up for the occasion, if too heavy, by the addition of mould, sand and gritty matter; also let it be raised some 6ins. above the surrounding surface. In all cases, too, add a heavy dressing of fresh littery farm manure to the upper spit, a load to two rods being by no means excessive. Leave the surface rough and scatter a little slag or lime over it. During winter and again in early spring fork the surface spit over and, at the last occasion, scatter some wood ashes freely before doing so. I do not, in general, urge autumn planting for various reasons except when the soil has been thoroughly prepared in advance. The plants are placed in a first-class bed 18ins. apart, and probably the ideal plan for a garden is to have three rows together, then an alley 2ft. wide at least.—L.

Making the Most of Cabbages, Cauliflowers, Greens, etc.

HOW many gardeners have noticed that when picking Brussels sprouts if the partly formed buds are left they soon produce good "buttons" or heads. When you cut a cabbage, do not uproot the stump, unless you wish to plant something else in its place. If the stump is green and full of sap, it will soon produce a few clusters of small crisp leaves resembling Brussels sprouts. These are useful for culinary purposes. Instead of cutting off the whole head of a cauliflower, leave a part on, the size of a gooseberry, and all the leaves. Second and even third heads will be formed, and may be eaten for two or three months. If, however, you cut the heads completely off, the plot of cauliflowers is gone in some two or three weeks' time. Cauliflowers, I find, grow best in good rich and moist soil, and treated somewhat in the same manner as celery. Like other plants of the cabbage tribe, cauliflowers rejoice in a well manured soil.

Colewort, or cottager's early kale, is another vegetable which may not only be made to yield successive supplies of nice crisp leaves, but the thick, strong thongs or runts when two years old may be made to provide a supply of nice young slips which may be planted like flower cuttings in boxes or in a bed, and when rooted may then be planted out in the same way as seedling plants. This is an excellent way of preserving any fine curly variety. Another advantage is that these cuttings or slips taken from old stumps in April will often be weeks, if not months, in advance of autumn or spring sown plants, especially in cold districts where the frosts are severe. In the far north, instead of sowing curly greens in August or September, I find it generally more successful to sow the seeds on a northern exposure, on rather poor soil, in May or June. These seedlings make a slow and comparatively sturdy growth. That is, they grow rather small leaves and form good strong stems. They may stand in the seed-bed until next March or April, when they are planted out. These plants usually withstand the hardest of winters, and when planted in well worked and well manured soil in the springtime they soon make vigorous growth, striving, as it were, to recover lost time.—K.

The Treatment of Soil for Spring-Planted Trees.

AUTUMN planting is much better than spring planting, because the soil is warmer and new roots grow and permeate the soil to some extent, but all lovers of hardy fruits are not in a position to plant the trees in the autumn; many of them must, through circumstances, delay the actual planting until the spring. Where it is convenient to prepare the ground for them, no time should be lost in dealing with it. Where isolated trees are to be planted the soil for each one should be trenched 30ins. deep over a space measuring at least 6ft. across. The lower portion of the soil should be well broken up, but left below. Where small plantations are to be made, the whole of the soil should be trenched and the holes made in readiness for the roots of the young trees. Do not break up the soil, but leave it lumpy in and around the holes, then the rains and frosts of winter will sweeten and pulverise it. Spring planting should not be done later than the early part of March.—CHRISTCHURCH.

OUR SERVICE BUREAU

Cutting Back Romneya Coulteri.

I have three good Romneya Coulteri plants raised from root cuttings. One has flowered very well this year and the other two moderately. I take it that as the blooms come on the new wood it would be well to cut them right down for the winter and protect the stumps.—E. S., Bromley.

Do not cut the growths down of Romneya Coulteri, but leave them to die down naturally, or, at least, leave the growths for the frost to kill them down. Protect them with bracken or old Michaelmas daisy stems, and if the ground is at all damp place ashes round the stems. If any stems remain, cut off at the end of March.

Soil for Spiræas.

What is the most suitable kind of soil for spiræas and astilbes? Would cow manure be too strong?—F. A., Highbury.

Top spit loam soil from good meadow land is the best compost for the spiræas. Cow manure will be very useful and will enrich the soil, but do not use it straight from the sheds. Stack it in a heap for three months and turn two or three times before using it.

Fruit Trees for Walls.

Would you advise me what varieties of fruit trees and fruit bushes would be suitable for training around three walls of a garden. Each wall is 100ft. long and 6ft. high and gets a fair amount of sun. Regarding the fruit trees, I wish to grow dessert and cooking apples and pears.—R. R., Exmouth.

Fruit bushes can never be trained against a wall. Apples are rarely, if ever, trained as wall trees. For pears we suggest Doyenne du Comice, Winter Nelis, Jargonelle, Souvenir de Congres, Josephine de Malines, Beurre Superfin, Louise Bonne of Jersey, etc. Pears should be grown on an east or west wall. Plums may also be grown on these aspects. For a south wall peaches, nectarines or apricots may be grown. Under a north wall gooseberries and red currants may be grown. Morello cherries should be grown on a north wall.

A Hedge Plant for a Small Garden.

I wish to plant a hedge screen at the back of my garden which is 50ft. across. I should like the hedge to have rather a thick bottom and thought of planting privet with Lombardy poplar, or prunus, or mountain ash at intervals. Your opinion as to best material and distance of planting will oblige.—B. G., Lincoln.

We suggest that you plant for a hedge screen at the bottom of your garden Cupressus macrocarpa. This is a plant which has become more popular every year for hedge purposes, and is both attractive and serviceable. It should be planted about 2ft. apart, and plants of 1–2ft. high can readily be obtained. It reaches a fair height, but can be cut backat intervals during the summer months in order to produce bushy growth from the base. It grows readily in the majority of situations. As this is evergreen, it should be planted as soon as possible, or left over until the month of April next year. Planting should be done carefully, as if the roots do not get a hold of the soil quickly several of the plants may die.

Climbing Plants for a North Wall.

Will you kindly give me a list of the best roses and other climbers for the north wall of a house, not ivy or ampelopsis?—G. R., Hereford.

We advise you to try some of the following plants, all of which will be suitable for your purpose: Berberises Darwinii and acuminata; Clematis Jackmanii; Jasminums nudiflorum and officinale; Kerria japonica; Pyracantha Lalandei; Roses Alberic Barbier, Lady Gay, Mermaid and American Pillar.

Ripening Tomatoes.

In consequence of the sunless weather, tomatoes which I have grown in a cold greenhouse have not ripened; I have now picked them off the plants and wish to know the best method of ripening them?—N. H., Harrogate.

To ripen tomatoes, place them on a sunny shelf or else in single layers in cardboard boxes in a cupboard. Examine them every three or four days.

NEW PLANTS AT VINCENT SQUARE.

THERE was quite an interesting collection of novelties before the Floral Committee of the Royal Horticultural Society at Vincent Square on November 1st last. The outstanding feature was the lovely sprays of Eucalyptus leucoxylon which Mr. Cecil Hanbury sent from his famous garden at La Mortola, Ventimiglia, Italy. This species becomes a tall tree with more lower branches than have most of the eucalypti. Usually the flowers are white, but now and then a pink form occurs and this is very beautiful. The way of the eucalypti is very interesting. When their time comes the fat greenish flower buds push off their caps entire, disclosing the closely packed floral filaments which gradually separate and become feathery, rosy pink flowers. The eucalypti have three distinct types of foliage—the seedling, intermediate and adult; the only constant character of the genus lies in the formation of the flower buds and, even better still, in the seed capsules which follow the flowers. Unfortunately, the more beautiful of the eucalypti from the flower point of view are not hardy in this country, and they grow too tall for all but the largest conservatory.

Euonymus grandiflorus, shown by Sir Charles Cave, Sidbury Manor, Sidmouth, South Devon, is a sturdy, robust spindle tree that was introduced from Nepal in 1824. The sprays had lanceolate, shining green leaves and large fruits from which the dull red arils were just showing. The fruits were lightly flushed with blush purple, and were not so showy as in several other species. The Hon. Vicary Gibbs again showed large sprays of a cotoneaster presumed to be C. alderhamensis and to have been collected by Forrest. This time it received the award of merit. It is a robust, spreading bush bearing axillary clusters of small bright berries.

Crinum zeylanicum, which Sir William Lawrence sent from Burford, Dorking, is a very old tropical species which has been in cultivation since 1771. The illustration in the *Botanical Magazine* 1253 gives a splendid impression of the uncommon, broad, reddish band of colour which runs down each floral segment on white ground. The two scapes were about 2ft. 6ins. in height and bore six and seven flowers. Considerable fragrance is usually associated with this tropical Asian and African crinum, but very little was to be detected in the specimen shown. As with most crinums, this species has ample leafage and so is a plant only for those who have large glass-houses.

Two chrysanthemums also received awards of merit, and both were shown by Mr. H. Shoesmith, jun. The variety Pax is a valuable Japanese of rather more than medium size. The round blooms are made up with stout white florets. The centre of the flower is often tinted with creamy yellow. Daphne is a large single of only moderate form. There are several rows of rosy mauve ray florets.

Slugs and Soil Pests banished

Peril following wet season controlled by prompt action

Everywhere slugs are teeming, favoured by the wet season. Now is the time to take them in hand. STEROLE, the proved specific, kills Slugs and all Soil Pests. Just dig in STEROLE wherever land is cleared, or fork in between plants on permanent borders. STEROLE is cheap! STEROLE is certain!!

"Since using STEROLE on lettuce beds infested with slugs I have never had to replant. Please repeat order."—EVESHAM.

"I have great pleasure in testifying to the splendid qualities of STEROLE. It is magnificent stuff, and does its work extremely well. I have used several other brands of insecticide, but none comes up to your STEROLE."—NURSERIES, RAYLEIGH, ESSEX.

THE GARDEN

VOL. XCI.—No. 2920. NOVEMBER, 19 1927 PRICE TWOPENCE.

AUTUMN TREATMENT of TREES and SHRUBS

WITH some flowering shrubs, the lilacs and forsythias are examples, it is necessary to prune and thin the branches when the flowers fade if the best results are to be obtained. There are others, the philadelphuses and diervillas are instances, in which pruning is best done at the close of the flowering season, but not being so essential is often left, through stress of work in summer, until the general overhaul of the shrubbery borders and beds begins in late autumn.

The question of pruning many of the berried trees and shrubs may now be considered. In a number the fruits have fallen, or eaten by birds; others, still very attractive, cannot at present be dealt with. Most berried shrubs flower on the growths, or from spurs on growths, of the previous year. Hence any pruning and thinning of the shoots must be done with care to preserve all the best young wood. Taking the barberries, which are so attractive in fruit, as an example, the aim must be to thin the shoots by cutting out a few of the oldest branches back to the main stems. To shorten the branches would not only mar the beauty of the long, slender growths in fruit, but would make a still more tangled mass of short twigs. Most of the barberry bushes will also be improved by the removal of thin, weak branches crowding the centres of the bushes.

The philadelphuses, or mock oranges, are a very good example of deciduous shrubs which flower freely on the young growths of the previous year. First of all, if not done already, cut out the old flowering wood on which there are no useful young shoots. Then cut out useless crowded weak twigs and, finally, shorten very long growths, which in time would destroy the shape and symmetry of the bushes.

In very many gardens sufficient attention is seldom given to the cultivation of shrubbery borders and beds. As opportunity occurs the ground should be forked through, digging in old decayed manure, "Adco" manure or bone meal. The latter, in the absence of farmyard manure, is one of the best manures for shrubs.

Now that the leaves are off the wistarias the final spur-pruning of the young growths of the year not required for extension is necessary. The spur-pruning of these is somewhat on a par with apples and pears, the shortening of the shoots to within two or three eyes of the old wood causing the formation of the flower-buds.

The pruning of the pyracanthas on walls and in the open must be undertaken with judgment. All that can reasonably be done when the branches are clear of fruits, is to shorten the long branches. Should hard close pruning be decided upon, this is best done in April when new growth is about to begin, as it means the sacrificing of most of the flower and fruit for one season. In the case of overgrown specimens, this is quite worth while, as the pyracantha readily produce new shoots from fairly old wood.

November is the best time to do this work, and then there is the opportunity to undertake most of the planning and planting while the weather is mild and the ground warm to encourage new rooting before the coldest days of winter.

Aucuba.—Shorten long growths back to side shoots.

Berberis (deciduous).—Thin bushes by cutting out old branches entirely back to main stems and remove weak twigs.

Bignonia.—Shorten long trailing branches on walls back to within two or three eyes of the old wood unless there is more space for vigorous young wood.

Buddleia variabilis.—Cut back the new strong growths of the past summer to within 1ft. to 1½ft. of the old wood and remove thin twigs.

Colutea arborescens.—Cut back to within 2ins. to 3ins. of old wood.

Diervilla.—Cut out old flower branches and remove weak twigs, retaining the best and strongest of the new growths.

Ilex (holly).—Shorten long shoots, destroying the symmetry of trees and shrubs.

Jasminum officinale (white jasmine).—Shorten long trailing growths on walls and fences. Nail in vigorous young shoots required to extend the size of the specimen or replace the old worn-out wood.

Laurus nobilis (bay laurel). — Shorten vigour shoots spoiling the shape of the plants. Defer all hard pruning until April.

Lavandula (lavender).—Trim off all old flower- stems and loose ends with shears.

Philadelphus (mock orange).—Remove old flowering wood and weak twigs. Shorten extra long vigorous growths spoiling the shape of the bushes.

Potentilla.—Cut out a few of the oldest branches to keep the bushes thin and open.

Pyracantha.—Shorten long branches when free of fruits on walls and fences. Defer hard pruning until April.

Rubus (white-stemmed brambles).—Cut out all last year's stems down to the ground to show up the beautiful colour of the shoots of the year.

Spiræa (spring-flowering).—If these were not pruned in early summer cut out a few of the oldest branches, some down to the ground, to keep the bushes free and open in growth.

Wistaria.—Spur back all young growths not required for extension to within two or three eyes of the old wood.

This Week's Work

For Gardens in the South and Midlands.

Cut out old wood from flowering shrubs.

Plant fruit trees, roses and herbaceous perennials and turban ranunculi.

Insert cuttings of gooseberries and currants.

Stake all newly planted trees.

Pinch growths of autumn sown sweet peas.

Remove early bulbs in pots from plunging ground to partial shade indoors.

Protect broccoli and lift seakale and rhubarb for forcing.

Give protection to tender plants in the rock garden.

Ventilate violets in frames and guard against damping.

This Week's Work

For Gardens in Scotland and the North.

Plant ranunculus in light soil.

Pot a few plants of lobelia to provide cuttings.

Lift all root crops and store in sand.

Look over bulbs in ashes and remove those sufficiently advanced.

Take cuttings of perpetual flowering carnations.

Stake clarkias and schizanthus.

Pinch sweet pea seedlings that show two pair of leaves.

Hoe between rows of kale and Brussels sprouts.

Continue planting roses and fruit trees.

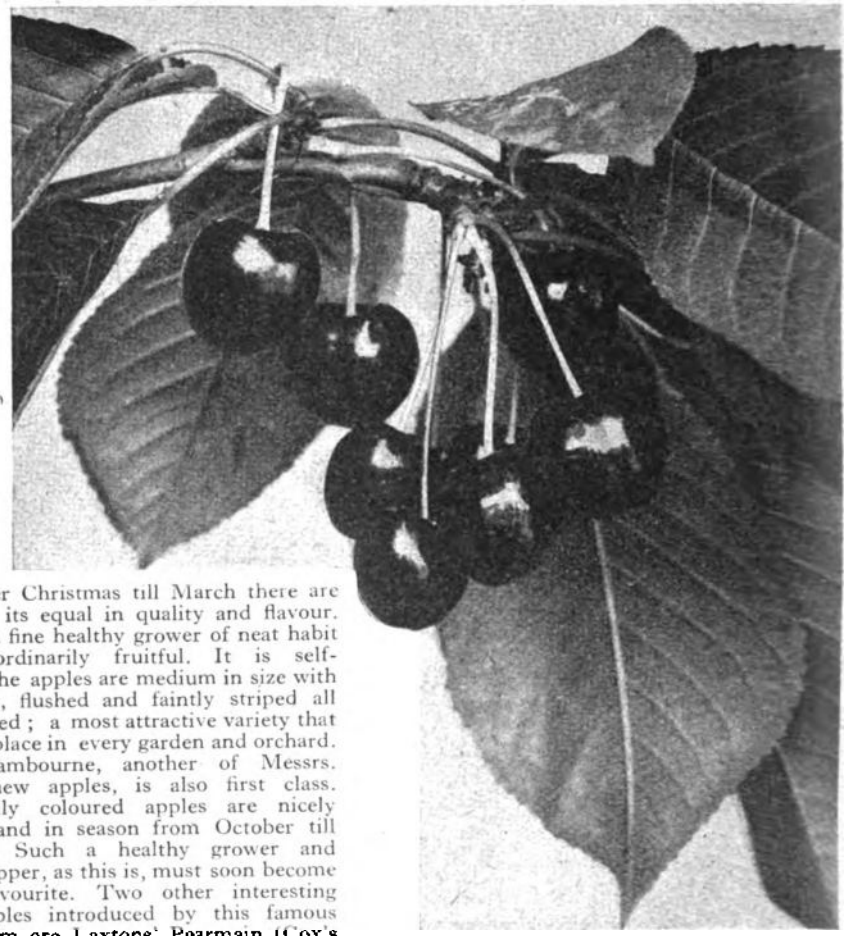
Move geranium cuttings from cold frame to greenhouse.

Plant hardy rhododendrons.

Digitized by Google

SOME GOOD NEW FRUITS

AT the height of the fruit planting season we take this opportunity of bringing to the notice of our readers several novelties among fruits that have been introduced in recent years. A brief but fairly complete survey has been made, and these new varieties that are described can be thoroughly recommended for planting by all amateurs. An endeavour should be made even in small spaces to grow a few of these choice fruits. They will add to the beauty as well as the general economy of the garden.



ONE OF THE FINEST OF THE NEW CHERRIES URSULA RIVERS.

IN these enlightened days a "new" variety of fruit stands little or no chance of finding favour in the public eye unless it shows marked improvement, in one respect or another, upon the certain old-established varieties of similar type and season.

It is seldom realised, perhaps, that of the hundreds of "seedling" fruit trees and bushes raised each year by experienced plant breeders and enterprising nurserymen (also by enthusiastic if mis-guided amateurs) the great majority—perhaps as much as 98 per cent.—are discarded as being inferior to existing varieties! And even among the small percentage that survive this preliminary combing out, to live to become "named varieties," there will possibly—almost certainly—be some that default when the test of "time" is applied and they have been grown and tried in gardens and orchards over the country.

Of the several "new" fruits of comparatively recent introduction which have, to some extent, proved their worth, reference is made to a few in these notes.

In the very front rank of new apples is Laxtons' Superb, raised from a cross between Cox's Orange Pippin and Wyken Pippin. This might be said to be *the* late dessert apple to follow Cox's Orange, and from shortly after Christmas till March there are few apples its equal in quality and flavour. Superb is a fine healthy grower of neat habit and extraordinarily fruitful. It is self-fertile. The apples are medium in size with yellow skin, flushed and faintly striped all over with red; a most attractive variety that deserves a place in every garden and orchard.

Lord Lambourne, another of Messrs. Laxton's new apples, is also first class. The prettily coloured apples are nicely flavoured, and in season from October till December. Such a healthy grower and reliable cropper, as this is, must soon become a wide favourite. Two other interesting dessert apples introduced by this famous Bedford firm are Laxtons' Pearmain (Cox's Orange Pippin × Wyken Pippin), a "brother" to Superb, beautifully flavoured and keeping till April; and Exquisite (Cox's Orange Pippin × Cellini), a striped apple to eat in September and October. Both are promising sorts of neat habit and great fertility.

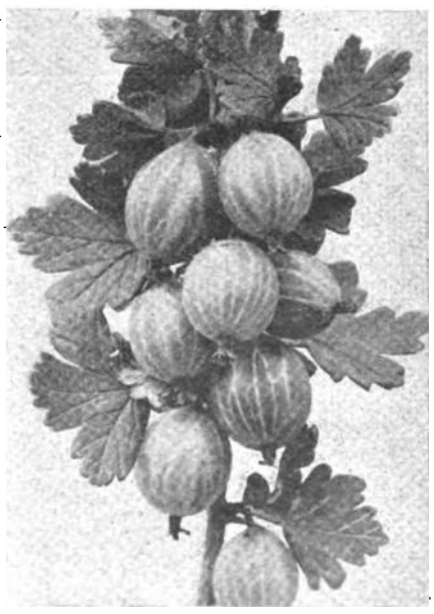
St. Cecelia, a seedling from Cox's Orange Pippin introduced by Mr. Basham of Basaleg Nurseries, is another splendid new dessert apple that makes excellent fare round about Christmastime, and later. The handsome apples are a nice size for dessert—never too large—and of very good flavour. This variety makes a neat tree for garden planting and can be recommended.

Upton Pyne, raised at the Denver Nurseries of Mr. Geo. Pyne, is a valuable "keeping" variety. The apples are golden with pale stripings and are equally good for dessert or culinary purposes. As a late-keeping, dual-purpose heavy bearer this bids fair to reach front rank.

Coming to culinary apples, the variety Monarch (Peasgood's Nonsuch × Wellington) is among the foremost of new sorts. Introduced by Messrs. Seabrook of Chelmsford, this is a strong grower and remarkably free cropper, the apples being very large, yellow, flushed with bright red and keeping till April. It will almost certainly supersede some of the older "cookers" of similar type and season now being grown. Encore, introduced by Messrs. Cheal of Crawley, is a pre-war introduction, but worthy of mention in that it makes a fruitful tree of compact habit, and the fine big greenish yellow apples keep till June with very little trouble. Another introduced by Messrs. Cheal is Crawley Beauty. The brightly striped apples cook splendidly and are borne in amazing quantities in most seasons. This is one of the latest flowering apples we have, and in frosty gardens, and others, should be of great value. It is rather a flat, spreading grower.

John Waterer, a very large green apple, introduced by Messrs. Waterer of Twyford, is another fine culinary apple that can be recommended; while S. T. Wright, a brightly striped mid-season variety introduced by Mr. Allgrove of Slough, should prove as valuable in the fruit garden and kitchen as it certainly is on the exhibition table.

New varieties of pears are not numerous. Laxtons' Superb (Beurre Superfin × Williams) is undoubtedly one of the most outstanding.



GREEN GEM, A FINE NEW GOOSEBERRY VARIETY OF GOOD FLAVOUR.

LAXTONS' GAGE, A GOOD YELLOW PLUM AND A HEAVY CROPPER.

Digitized by Google

Ripening in August, it is deliciously flavoured; but, like all early pears, needs to be eaten within a few days of gathering to be appreciated. Superb is a fairly strong grower and fertile. A curious character of this variety is that young trees frequently are liberally furnished with strong "thorns" along the branches, but these develop into spurs in a few years if left. Beurre Bedford is superior in quality to many October pears and, being a strong grower and free cropper, it should soon become widely grown.

Messrs. Rivers of Sawbridgeworth introduced the two new cherries noted here. Ursula Rivers, a large black cherry of rich flavour is one *well* worth the gardener's attention. The second, Peggy Rivers, is much after the style of Governor Wood and ripens about the same time, but is an improvement upon this old favourite in that the cherries do not split so frequently when grown out of doors.

Coming to plums, we have Bountiful, introduced by Messrs. Laxton. The parentage is Red Magnum Bonum × Victoria, and the plums take after Victoria, but ripen a week or so earlier. It sets its fruit freely enough and makes a fine tree, being of much better habit than the old Victoria and much healthier. Laxtons' Gage, an oval, yellow plum, is another worthy of note, and this the raisers describe as "a gage with the crop of Victoria." It certainly is of delicious flavour and is fertile. Early Laxton, another new variety, is a strong grower, the yellow, red-flushed plums ripen very early, a full week before some earlies are fit to eat. Allgrove's Superb, a red "sport" from the well known Jefferson plum and introduced by Mr. Allgrove of Slough, is becoming deservedly popular. Ripening at the end of August the red, much-speckled plums are delicious and are produced freely in favourable seasons.

In black currants perhaps the outstanding introduction of recent times is Daniels' September, raised by Messrs. Daniels of Norwich. The immense berries ripen just after Baldwin and hang late, well into August and even September in favoured districts. Like the old Baldwin, it is very early in flower, makes fine bushes and crops heavily, and might be briefly described as "an improved late-hanging Baldwin." Davidson's Eight, introduced by Colonel Petre of Westwick, is a new variety of sterling merit; better known to commercial growers than to gardeners. This is quite one of the heaviest bearers and the flavour leaves little to be desired. Laxtons' Mite Free, introduced by Messrs. Laxton, is a splendid cropper and healthy grower too. No variety yet raised is immune to the big bud pest, of course, but the varieties classed in the French group (such as Seabrook's Black and Laxtons' Mite Free) are undoubtedly less susceptible than most others. Blacksmith and Tinker are two other big-berried new varieties distributed from the Bedford Nurseries.

Laxtons' Perfection is perhaps the biggest berried of all red currant varieties, and is fast becoming the general choice. It should be planted in a sheltered corner or grown as a cordon along the pathside or fence. Laxton's No. 1, a newer variety, is a strong upright grower, but the berries are not so big as Perfection, though borne equally or more freely.

There are several good new raspberries. Lloyd George must be taken as the "standard," for this is quite the finest all-round raspberry in cultivation—in spite of it being such a rampant grower. Royal, introduced by Mr. Pyne of Denver Nurseries, Topsham, is undoubtedly a variety of exceptional merit and is almost certainly the largest raspberry grown—in this case good flavour going with size. Another from Mr. Pyne is Red Cross, a remarkable cropper and good grower. The berries are nicely flavoured, though a little more acid than some, perhaps. For flavour alone Park Lane, sent out from the Denver Nurseries, must take pride of place. It is quite the best for dessert, though the big, tall canes are apt to die back rather alarmingly, so many making "blind" buds. Heytor, from the same source, is one of the best new autumn-fruiting raspberries, and Golden Hornet, raised by Mr. Trinder of Fleet, is a good yellow raspberry of recent introduction, as is Messrs. Laxtons' Yellow Hammer.

For new gooseberries of merit we must look to Messrs. Laxton with their Bedford Yellow as the finest. The very large golden yellow berries, of delicious flavour, are produced in great profusion. Green Gem is another good new variety of fine flavour, and the strong, upright-growing Bedford

THE FINEST ALL-ROUND RASPBERRY IN CULTIVATION, LLOYD GEORGE.

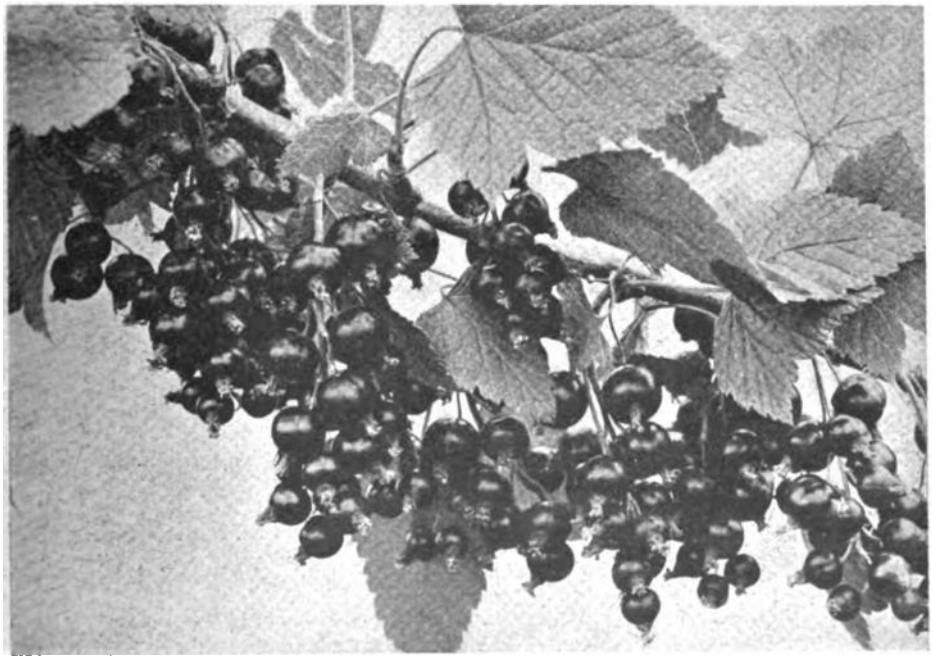
Red is perhaps the outstanding red gooseberry of recent years.

Among the "various" berries, the Veitchberry, introduced by Messrs. Laxton, is well worth a trial in every garden. Raised by crossing November Abundance raspberry with the blackberry, this new fruit is rather unique. The large berries, so well illustrated on our front page this week, ripen when raspberries are over and before blackberries come in, and are the colour of ripe mulberries. flavour partakes a little of both parents. The cultivation, pruning, etc., is as for the loganberry. It is one of the new bush fruits that every amateur should have in his garden, since it is easy to grow and is a reliable cropper.

The Himalaya Giant blackberry is hardly a recent introduction perhaps, but is worthy of note here in that it is extremely vigorous and remarkably fertile, and just the thing to plant in the garden to shut off untidy corners, rubbish heaps, etc., or to climb over a shed or big trellis. The berries are large and black, also very sour unless gathered "dead ripe" for eating.

The Worcester berry, said to be a cross between a gooseberry and black currant, and introduced by Mr. Parsons of Worcester, makes big bushes, the branches being armed with immense spines. The berry is to all appearances a small, purplish gooseberry, and the flavour—what there is—is a mixture of the two with the currant flavour distinctly less than more. Pruning and general cultivation is on the same lines as for gooseberry bushes.

From the selection given above the amateur may be able to make a choice of a few new varieties of fruit to add to his collection. All the sorts mentioned can be thoroughly recommended for planting in the small garden.



A WELL-FRUITED BRANCH OF LAXTONS' MITE-FREE BLACK CURRANT.
It is one of the best mite-resistant varieties yet raised.

HARDY FLOWERING PLANTS

For the Suburban Garden.

CAMPANULAS ARE AMONG THE MOST DECORATIVE OF HARDY PERENNIALS.

VERONICA SPICATA IS AN ADMIRABLE SHRUBBY PLANT FOR THE BORDER.

THERE is no more keen admirer of hardy flowering plants, or one who appreciates to their full value their inclusion in a garden, than the gardener who lives in the suburbs. He it is who recognises the importance of having flowers for as long as possible, that are not only beautiful when seen from the windows of his home, but which will also serve him in a cut state for embellishing his rooms and tables. The time has gone by, to a large extent, when flowering plants of a tender nature occupied his time and attention with their annual expenditure and trouble.

Now something of a more enduring character is required, and in hardy plants he finds all he needs in this direction. In these late autumnal days when plans are being made for another year, one finds the lover of hardy plants either contemplating adding to his treasures, or dividing some of those he possesses. With many plants this time of the year, given suitable weather to get on with the work, is as good a period as any, and a consideration of some of those which render the best service throughout the season is suggested. It may be said concerning most hardy plants that, once quartered in a garden, they give little trouble, beyond the annual inspection, and in some of the more robust-growing sorts in frequent division, and it is their simple culture coupled with their freedom of flowering that every year is making them more popular. If we want tall plant for the back of a border, or those of comparatively dwarf growth for beds and the front of borders, we can find all we need in the realm of hardy subjects, and to complete all, should we want a compact or prostrate growing plant for the edging, we have no need to go outside their boundary. In a word, hardy plants will supply us with a feast of colour from the early days of spring until late in the autumn, and there is no garden, however bleak its situation or however closed in it may be, where some of them at least will not thrive and do well.

LIST OF HARDY FLOWERING PLANTS.

Name of Plant.	*Height.*	*Flowering Period.*	*Remarks.*
Doronicum austriacum	1–2ft.	March-April	Sun or shade.
Funkias or Plantain Lilies—various	2–3ft.	May-June	Best in partial shade; vigorous.
Trolliuses or globe flowers	2–3ft.	May-July	Sun or shade.
Peonies	2–3ft.	May-June	Deep rich soil; sun or partial shade.
Aquilegias	1–2ft.	May-July	Sunny position.
Irises (flags)	2–3ft.	May-June	Sun or partial shade; vigorous.
Geums	2ft.	May-Sept.	Sunny position, chalky soil.
Dicentra or dielytra	2ft.	May-July	Sun or shade. Rich light soil.
Oriental poppies (papaver)	2–3ft.	May-June	Ordinary soil, well drained.
Pyrethrums	2–3ft.	May-June	Rich, medium soil.
*Alstrœmerias (Peruvian lilies)	3–4ft.	June-August	A deep light soil and sunny position.
Hemerocallises (day lilies)	4ft.	June-August	Sunny position.
Delphiniums	4–7ft.	July-August.	Deep, rich soil, sun; vigorous.
Campanula persicifolia	2–3ft.	June-Sept.	Ditto.
Gaillardias	2ft.	July-Sept.	Dry soil, sunny position.
Heleniums	3–4ft.	July-Sept.	Sunny position.
*Gypsophila paniculata	3–4ft.	July-Sept.	Sunny position; deep, chalky soil.
Spiræa filipendula	1–2ft.	July-Aug.	Shade-lover.
Kniphofias (red hot pokers)	4–6ft.	June-Sept.	Deep rich soil.
Michaelmas daisies	1–6ft.	July-October	Any ordinary soil; vigorous.
Anemone japonica	3ft.	July-October	Ditto.
Phloxes (autumn-flowering section)	1–4ft.	Aug.-October	Rich, deep soil.
Veronica spicata	3ft.	July-August	Any fairly good soil.
Thalictrum aquilegifolium	3–4ft.	June-August	Sunny or partially shady position in good, well drained soil.
Hardy Plants Suitable for Edging Purposes.			
Aubrietias—various	3–4ins.	March-May	Light, sandy soil; sunny position.
Campanulas carpatica, turbinata, pulla	6–8ins.	May-July	Ditto.
Myosotis (forget-me-not)	6–8ins.	May-June	Shade or sun.
Iberis (evergreen candytuft)	9ins.	June-August	Ordinary soil; sun.
Thymus serpyllum (wild thyme)	4ins.	June-August	Dry, sandy soil.
Pink, Mrs. Sinkins	6ins.	June-July	Ditto.
Nepeta Mussini (catmint)	6–9ins.	May-August	In any well drained soil.

Suggestions for Furnishing.

In contemplating furnishing new beds or borders in a garden in the suburbs, the difficulty is not in being able to select a few plants which have a reputation for doing well, but to choose from the very many those which appeal to us, and will give blossoms for a long time. With this in view, we have prepared the undermentioned list as a guide to the would-be planter, and from that list he will be able to determine what to obtain. Before any attempt is made in getting in plants, the ground should be well dug and,

Digitized by Google

if known to be poor, some rotted manure or, failing that, vegetable refuse or leaves worked in the bottom spit. If it is convenient to do so, trenching or double digging, at least, of the ground should be carried out, as in the case of some hardy plants (*) mentioned on previous page which are best left alone once they are established; indeed, to disturb them when they have been growing a year or two is little short of a mistake; hence the desirability of seeing that the ground they are to occupy shall be thoroughly dug and rightly supplied with suitable soil for those plants of a special character. A word is, perhaps, needful as to the advantage of not overcrowding a border or beds at the first onset. It never pays to overcrowd, least of all with hardy flowering plants, and therefore it is well to study the habits of the varieties to be grown, and leave space accordingly for proper development. W. L. L.

A SELECTION OF RAMBLER ROSES

RAMBLERS, for the most part, are hybrids either from Rosa Wichuraiana or from varieties descended from that species. Dorothy Perkins is, perhaps, the best known example of a Wichuraiana rambler. It has found its way into almost every garden where roses are grown, and it has become so firmly entrenched in the affections of growers that it is practically impossible to displace it. No one will deny the beauty of Dorothy Perkins and its value as a rambler for the adornment of pillar, post, fence or pergola, or for use as a weeping standard, but it is, I think, a mistake to say that it is actually the best of its colour. For my own part, if I wanted to plant what I believed to be the best rambler of this type I should prefer Minnehaha. This lovely rambler has suffered from the extreme popularity of Dorothy Perkins, and it has never received the attention which its undoubted merits deserve. It is altogether a rose of much more refinement than Dorothy Perkins, and its truss of deep rose blossoms is decidedly more attractive and artistic.

I have mentioned Dorothy Perkins to begin with as it is very representative of the type that we are dealing with in this article. Ramblers of this character, Wichuraiana hybrids, are not seen at their best on walls; the place for them is a fence, preferably of open woodwork, where air and light can get at them all round. They are equally valuable for use on pillars, pergolas, or trained on arches. In some gardens chains or wire ropes are supported on posts and the ramblers are grown along such supports. By such means a very beautiful display may be made in the garden, but strong rope is infinitely superior to anything else except wood. The whole of the ramblers are also good for weeping standards. The growth is naturally of a drooping nature, and it grows downwards very quickly. Some amateurs insist on getting their weeping standards with stems 4ft. high. This is a mistake. If the stem is 6ft., 7ft., or even a foot higher, the results will be much better. If the stem is only 4ft. high the growths will trail along the ground and most of their beauty is lost. If the stem is 6ft. or more in height, the growths hang gracefully down and will flower from top to bottom. A well balanced weeping standard about 6ft. in height is a beautiful subject when in full flower.

The well known American Pillar, although it is not a hybrid Wichuraiana, is grouped under this section. If anyone wants a strong climber which will thrive almost anywhere, this is certainly the rose for the purpose. It flowers very freely, and the single blossoms are pretty. The flowers are pink with a white centre. Caprice Rouge is a rambler with flowers about the size of those of American Pillar, but the colour is crimson, also with the white centre. It may be described as a glorified Hiawatha with a stronger constitution.

There are now two well defined types of ramblers. The first are the kinds of which Dorothy Perkins and Hiawatha are examples, and the second such sorts as Albertine and Emily Gray. We shall deal with the Perkins type first. They have small, rosette-like flowers borne in clusters. The others have larger flowers borne in couples and sometimes more. If a crimson rambler is wanted, the best is Excelsa. There was a time when the old Crimson Rambler—a climbing polyantha—was the best of its colour, but Excelsa has now displaced it. Many growers ask for Crimson Rambler when they really mean Excelsa. The old Crimson Rambler is not now required. Its faults are mildew and its liability to the attack of red spider. Edgar Andrieux is a red rambler well worthy of notice. It is derived from R. Wichuraiana crossed with the old Cramoise Superieure China. It is a good grower and has somewhat larger flowers than Excelsa, and its perfume is very sweet.

AMONG WHITE RAMBLERS THERE IS NOTHING TO BEAT SANDER'S WHITE.
It makes a decorative weeping standard.

Petit Louis is very similar to Dorothy Perkins in colour, but it flowers very much earlier. It produces a large spray of well formed little blossoms, and is a very strong grower. On the whole, I prefer it to the older sort, but both are useful. Petit Louis, if planted in conjunction with Dorothy Perkins, enables one to have a display of pink-flowering ramblers over a longer season than usual. If a paler shade of pink is wanted there is Dorothy Dennison. The colour is shell pink. Lady Godiva and Christian Curle are practically synonymous with Dorothy Dennison. Romeo is another red rambler that must not be overlooked. It has been described as a miniature Liberty. The colour is a deep crimson, and the flowers are very shapely. It is a good grower. Hiawatha is a single crimson, and a plant well established and in full bloom is very striking.

In white ramblers there is nothing to beat Sander's White Rambler. It is a good grower; it produces nice sprays of pure white flowers; and it is one of the sweetest of roses. In so far as perfume is concerned, it is, perhaps, the most fragrant of all. There is no room for White Dorothy Perkins when we have such a rose as Sander's White. Yvonne is a pretty variety with soft pink flowers, and Violetta has curious sprays of blossoms that are almost purple. It is abhorred by some and adored by others. Shower of Gold has sprays of orange yellow flowers. It varies in colour very much, however, but some seasons it is very fine.

In yellow ramblers Emily Gray stands supreme. It is the first to be mentioned of the large-flowering type. It is a beautiful thing even if it never flowered, for its foliage is large, has a wonderful gloss and polish, and reminds one of a showy evergreen shrub. The colour, which is fairly constant, is golden yellow. It has been described as resembling Mme. Ravary, but I think its flowers are far superior, both in colour and formation, although they are not so large. It is certainly a glorious rambler, and we want more of the same type. For a long time Alberic Barbier, also with wonderful glossy foliage, was a favourite rambler with fairly large flowers of a yellow tone. It was the best of the yellows, although the colour was a little pale. There is still room for it, as it is really a very beautiful variety when it is established.

Mermaid, although hardly a rambler in comparison with those of the Perkins type, must be included here. It has single yellow flowers that appeal even to those who seldom are attracted by single roses. Its foliage is also very fine. Mary Wallace, a semi-double, is also a good salmon pink rambler of recent introduction.

Of the many introductions to the Wichuraiana section recently I think that Albertine is the best. The flowers are large, and the foliage is glossy and mildew proof. The colour is a coppery chamois flushed with salmon. Paul Noel is a rambler with pretty flowers of an orange shade. It should be tried by all lovers of ramblers, as it is quite distinct from any other. François Juranville, salmon pink with a sheen of yellow, is another large-flowering rambler well worthy of inclusion in any collection. Joseph Billard is only a single, but it has flowers of a compelling shade of shining carmine that are most impressive and are not easily forgotten.

GEO. M. TAYLOR.

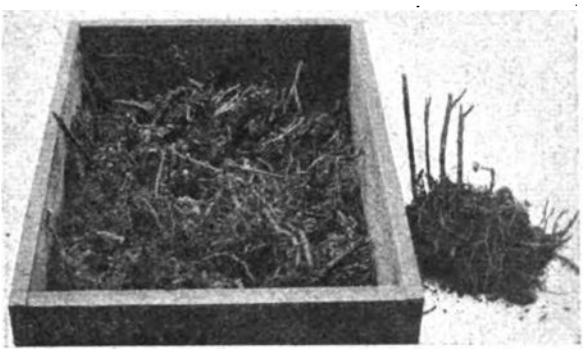
THE BUSY MAN'S PAGE

Fresh Parsley and Mint all Winter.

PARSLEY is required in the kitchen practically every day of the year, and it becomes rather a problem at times to keep up supplies all winter. As I write outside supplies are plentiful but a trifle soft; they will last for many weeks yet, but preparations should be made now to ensure later supplies. Place bricks about the bed and lay a frame sash or a sash made with one of those glass substitutes on top; the sides being open, this keeps the plants fresh and vigorous for a long time. Cover another section with a rough framework of poles or lay the pea trainers, raised on bricks, over the plants. Garden mats thrown on top of these in frosty weather will protect the border most considerably. Lastly, plant a fair number in boxes or pots. Place these meantime at the foot of a wall or in the frame, and in due course they can be cropped, or they can be taken into the greenhouse in spring, where, if fed at times, they will crop for a long period. Squares of mint may now be lifted from the mint bed and placed in boxes. Let such squares be about 3ins. deep and pack soil round them in the box. Placed over a hotbed or kept in the greenhouse such clumps will yield many nice pickings of fresh mint as required. As one supply begins to deteriorate lift another and so keep plenty ready for any call from the kitchen.



METHOD OF PLACING ROOTS OF MINT IN BOXES FOR FORCING.
On the right is a section of the root as lifted from the bed outdoors.

THE ROOTS ARE COVERED WITH SOIL AND KEPT MOIST; IN A SHORT TIME NEW GROWTH IS MADE.

Digging and Trenching.

AN important point to be remembered in successful gardening is the necessity for thoroughly working the soil, and it is worthy of note that the beneficial results obtained from the extra labour entailed is becoming more widely known. From a gardener's point of view November is the month when the real foundation of successful cropping for next year is laid by digging and trenching; and where this is not done, severe frosts and possible heavy falls of snow may cause a postponement of this work until the New Year has considerably advanced, after which time it is difficult to make good the time lost. It is a good plan to trench a section of the kitchen garden each year, so that in a period of three to four years the whole garden has been so treated. On heavy soils where manure is being used, this may be applied at the time of digging or trenching, although with light soils this is best applied in spring, owing to the fact that a great part of its fertilising properties filters away before spring through heavy rains. In both cases, however, the soil should be left in as rough a state as possible; the action of frosts will leave it in a good friable condition, and is most beneficial.

Deep root action is encouraged by occasional trenching, and is most noticeable in periods of drought, especially if the surface soil is periodically stirred.

Protecting Tender Plants in Winter.

MANY of our choicest garden perennials are only half-hardy, and others, generally classified as hardy, may succumb to the trying vagaries of an average British winter. Frost is not the most serious trouble; heavy soaking rain which keeps the ground cold, sour and water-logged is undoubtedly dangerous, and strong sunshine after frost may be inimical to successful wintering. To keep out frost a mulch of some protective nature is frequently advisable, but it should not be used until the winter is well advanced, and in many cases it is advisable to remove it when frosts are absent or when they are light. The cover must never be such that it continues long wet in moist weather; a light littery mulch of old straw, ferns, ashes, leaf-mould, sand or peat is excellent, while manure which may remain wet and sodden is always a danger. A handful of evergreen prunings is very useful, small mats may serve, or even a cloche at times. Another variety of "cold," if we may use that term, is frequently dangerous—a cold drying wind followed perhaps by snow or sleet. Position is all important in this connection, and each grower must plant his tender stock with that point in view. Hurdles, boards or pieces of slate or glass come in handy as a protection when the plants do not have the shelter of a hedge or wall. Heavy rains are best prevented from soaking round plants by erecting over them a sheet of glass, but, once again, correct planting is essential; the places where plants likely to suffer are planted must be well drained and porous. A great danger is strong sunshine suddenly beating down on frosted plants, which causes sudden thawing. Lift plants likely to suffer in this way and replant in a west or north aspect or in some shady place, or see that cover of some kind is used overhead; this enables the thawing to proceed slowly. Get roots covered with their mulch, place evergreens or small mats where they can be had at a moment's notice and kept dry, have some ferns or twigs tied up amid tender branches, and place sheets of glass over small plants. Choice subjects may even be lifted and put in the frame, or potted up and stood in ashes under a sash open at the ends.

Jobs for Wet Days.

WET days are generally associated with the dull, gloomy days of winter, so that the amateur gardener looks round for something to do. "Digging in this weather," he says, "is foolish; but what am I to do?" Below are set out some of the jobs he can tackle, which will occupy his time with profitable result.

Firstly, tools can be cleaned and repaired. The most important, perhaps, are the barrow, lawn mower, roller and the various digging implements. Inspect these, and remedy any defects which are noted. If the handles of tools are loose, a little glue, or a wedge, will make them firm. Then the syringe plunger will need some vaseline, or it may require a new washer. Look around and you will see plenty of jobs among the tools.

When this is done, on taking a walk outside, when the rain has temporarily abated, you may see pools of water lying on the surface of the lawn. Prick the soil with the prongs of the fork to effect drainage. While outside, the drain could be cleared and any dead leaves removed from plants. Another important job is to roll paths, laying new ash or gravel down, if needed. Of course, the rolling will pick up a lot of the path, so a brush should be kept handy.

Assuming you have done all this, there is the very pleasant occupation of making things. Among the foremost of these are seed protectors, racks, boxes and labels. Soot and lime distributors can be made from tins with holes punched in the top. If you already have seed boxes, make sure they are safe, by nailing two strips of wood across the bottoms.

One thing which should not be forgotten is to look at the store room, and if any vegetables are going bad or shooting, remove them at once.

Before finishing here are a few things you can do if you have a greenhouse or a frame. You can whitewash walls, clean glass, scrub boards, and paint pipes. The woodwork and glass can be repaired where necessary. All this done, it will give you satisfaction.

Autumn Renovation of Small Lawns.

CAREFULLY remove worm casts and pour a solution of worm-killer into the exposed holes (a trowel of killer to a gallon). Too many worms cause the surface to be soft and muddy and their casts interfere with mowing. Remove worms that come to the surface, and mow the lawn closely.

Prepare a mixture of a good proprietary brand of lawn guano and sharp sand, in the proportion of one of guano to ten of sand, allowing 4 oz. of guano to each square yard. Mark out the lawn in suitable rectangles, with pegs, etc., and scatter the mixture evenly. After raking, water thoroughly. Make a mixture of ½ oz. of grass seed per square yard of sand and fine ashes, and two days after the guano application, scatter this evenly on the grass, rake thoroughly and use a light roller when the turf is dry. Mow carefully a fortnight later, without box, and with blades set high.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Alternatives to Grass.

THERE is no doubt that a patch of well kept grass adds enormously to the beauty of a garden; in fact, such a patch of grass, with merely a surrounding hedge of shrubs, can form the whole of a small garden, particularly a front or roadside garden. But even a small grass plot needs constant care and attention, and it needs also the use of both a mower and roller, if it is to be "well kept." In a very tiny garden, or in a garden where these tools will not be available, it is sometimes advisable to do without the grass plot. At the same time, one may wish to use the garden for meals, for rest, or possibly as a playground for the children, and the question arises, what is to take the place of a lawn?

Using Available Material.

It is often a question of using whatever material is available. Sometimes gravel can be dug from a few feet below the ground surface. This, if carefully laid and rolled on a subsoil which is well drained and levelled, makes a good smooth surface. If the whole of the middle of the garden is gravelled, and children are to use it as a playground, I should advise getting it tar-sprayed. The cost is not heavy, and the resulting surface is both cleaner and more lasting than gravel alone. If a quantity of bricks, or flat stones, can be used, much can be done by the artistic gardener in arranging them to best effect. A large semicircle, with a flower border round the edge looks effective in a small garden. In a long narrow garden I have seen curves introduced by arranging a wide path in the shape of a letter "S." In the circle at each end was a piece of stonework—one a sundial and the other a stone vase containing plants. The outer edges of the path were flanked by border plants of all descriptions, and the effect was to give added space in the garden.

Making Crazy Paving.

York stone paving is too expensive for many pockets, but a very good substitute can be made by running cement into wooden frames. The frames are laid on a levelled surface of the ground in a crazy sort of way. The cement is run into the spaces and, after it has set, the frames are removed. This work can be done in patches, and by using slightly differing sand in the cement, a difference in colouring can be made so that all the stones do not look exactly alike. (Red ochre or other colouring could be added to give variation.) The spaces between the cement are subsequently filled with prepared soil, and tiny plants, or grass seeds put in to clothe the stones. There is certainly some work attached to the care of a large area of crazy paving, but it can be done without special machinery, and at times can be left for weeks without attention.

For those who can afford to buy stone for their gardens there are plenty of materials from which to choose. Large square tiles make a very attractive flooring for an outdoor room, and the same tiles, built into square pillars about 18ins. high, are ideal sites for tubs or vases of flowers. By a judicious arrangement of such pillars and ornaments one can often give the effect, in a tiny back garden, of a veranda or loggia. The rose screen which separates us from the next garden may then, in imagination, be the screen between ourselves and the wider garden which our imagination conjures.

A Remedy for Wireworms.

SMALL, straw-coloured wiry worms about an inch long are often found in new garden soils. Old pastures newly turned over have the greatest numbers. Cultivation quickly reduces the numbers, but the first few seasons the wireworms work havoc among the root crops. The best remedy is a dressing of lime—6 ozs. to a square yard—before digging is done. Clean cultivation helps to rid the garden of these pests, and they may be trapped by burying in the ground pieces of potato. The spots should be marked and the traps examined every few days, when the wireworms can be destroyed.

Original Garden Designs.

A REMARKABLE progress in the matter of design has been made in the average amateur's garden during the last few years. Originality and taste of a high very degree have shown themselves, and gardens no longer bear the impress of the jerry builders' ideas on garden construction. Now that the days of winter sleep draw near, those of us who wish to remodel our gardens should be prepared with definite plans for the work. It is much easier and more satisfactory in the long run to have a plan of the garden drawn to scale, so that mistakes in measurements, etc., can be avoided.

A GARDEN DESIGNED BY AN AMATEUR, WHICH IS EFFECTIVE IN ITS SIMPLICITY.

Here is a garden designed and made by an amateur, which is remarkably effective in its simplicity. The brick path which crosses the lawn and also forms a circle round the flowers and sundial, is an extremely happy thought. Ample room is left for the cultivation of flowers, climbers and for rock plants at the end where the low stone wall edges the lawn. The whole plan is such as could be carried out by a keen amateur without the employment of skilled labour, and at the same time could hardly be improved upon by any professional garden designer.

Lilies After Flowering.

JAPANESE lilies, both the golden-rayed and pink and white kinds, are frequently grown in pots or in the open border. Their lovely blooms have now fallen, and we wonder how to make the plants excel in beauty another season. Cut away the dead flowers, but allow all the leaves to remain on as long as possible. Water with soot water once a week, but as soon as the leaves turn yellow withhold water altogether. The pots can be laid on their sides in a dry frost-proof shed until it is time to start the bulbs again in early spring. Lily bulbs grown in the open border can be left if the soil is well drained. Should it be naturally wet and heavy, it would be safer to lift the bulbs and store in boxes of sand or dry soil.

Double *versus* Single Flowers.

I WAS shown round a friend's garden the other day, and he led me with great pride to a double-flowered scarlet nasturtium. This was exhibited for the first time a couple of seasons ago at Chelsea. My friend's enthusiasm led me to reflect on the relative merits of double and single flowers. The true botanist, I am sure, would prefer single flowers always. Double flowers are a monstrosity, a reversion, and in a state of nature, impossible. It is significant that single flowers of some of the most popular kinds, such as dahlias and chrysanthemums and roses, have grown in popularity in recent years. When a double flower does appear, like the nasturtium, for the first time, it is much sought after as a novelty, but I feel certain that this is only a passing phase.

Fruit Trees for Walls.

MANY gardens where there is insufficient rooms for bush or standard fruit trees could add to their beauty as well as to their utility by the inclusion of wall fruits, and there are fruits which are suitable for almost every wall. As this is the season when new trees are purchased and planted, we give a selection of fruits which will do well in the positions indicated:

North walls.—Fan-trained Morello cherries, three or four cordon red currants, or fan-trained gooseberries.

South walls.—Cordon pears, dessert plums, peaches, apricots, and dessert cherries (fan-trained).

East walls.—Fan-trained Victoria plums, cordon apples and red currants.

West walls.—Victoria plums, greengages, cordon pears and apples.

The distance apart for cordon trees depends on the kind, but is roughly 2ft. to 3ft. Fan-trained cherries and plums would need 15ft. or so of space, when well grown. Where small trees are put in, the intervening space need not be left bare for the first season or two, as currants and gooseberries, or even tomato plants, can easily be grown to fill the empty places until the trees become full size.

NOTES ON THE FLOWER GARDEN

Japanese Maples for Autumn Colour.

IN many catalogues will be found a group of plants under the above heading, and they constitute a wonderful series, especially if planted for autumn effect. This year they have been exceptionally brilliant, and the trees and shrubs in the Tintern area of the Wye Valley have been more beautiful than I have seen them for several years. At the moment I have in mind the various Japanese maples, such as the forms and varieties of Acer palmatum, all of which are handsome plants when in leaf. The opening of the young foliage, the mature leaves of summer, and the charming tints seen in September and October place them among the best of our ornamental trees and shrubs.

Groups in the shrubbery border are sure to prove effective; a position in the flower border will also prove suitable for these delightful plants. They are variable in habit of growth, and some of the smaller kinds, such as A. atropurpureum dissectum and ornatum are useful as isolated examples on the rock garden. Here a few have been a source of joy for many years; the soil is somewhat poor, so growth has been rather slow, but nevertheless they have never failed to produce ample leafage, which assumes such glorious shades of colour in autumn that appear almost scarlet when viewed from a distance on a bright day. A few varieties retain their charming colour throughout the season, such as A. sanguineum, a bush from 5ft. to 8ft. in height. The Japanese maples are quite hardy, but occasionally a late spring frost will cripple the young foliage, a fact, however, that ought not to deter beginners from planting a few of these choice shrubs. They will succeed in any ordinary garden soil.—T. W. B.

Plants for Hedges.

AS a hedge is to be a permanent feature it pays to give some consideration to the question of the plants to be used. Selection might be made from the following list, which includes some of the best subjects for the purpose.

Hawthorn, Whitethorn or Quick (*Cratægus monogyna*).—This is the commonest hedge plant in Britain. The plant has a naturally dense habit of growth and this, with the spiny branches, makes it a valuable protecting hedge.

Common Holly (*Ilex aquifolium*).—A holly hedge is about as good as anything where an evergreen is required. If well looked after in the early days the holly plants soon become furnished with branches from base to summit. Variegated hollies are sometimes used in hedge making, and now and again the large-leaved I. Hodginsii is employed, but these are not so good as the common species, which will grow in almost any soil or situation.

The Yew (*Taxus baccata*) is another fine evergreen hedge plant. At the start take care to choose plants which have several buds on them, in order to get a dense hedge within a reasonable time. The golden leaved varieties are also quite good as hedge subjects.

Privet (*Ligustrum ovalifolium*).—Although the privet hedge is regarded with some disfavour, it has the advantage of being cheap and easy to establish anywhere. Privet is apt to make the ground poor owing to its great root activity, and it is a good plan to open the ground by the side of an established hedge every few years and cut back the roots mercilessly. The golden leaved variety makes a bright hedge which give a cheerful winter effect.

Beech (*Fagus sylvatica*).—Beech in common with the hornbeam (Carpinus betulus) makes a capital hedge and it is largely used to form a wind break in exposed positions. A beech hedge will grow to a good height in course of time and, with care, there is no reason why it should not be well clothed right to the base. Usually the dead leaves are retained throughout the winter and this increases the value of the beech hedge in keeping back cutting winds.

Myrobalan or Cherry Plum (*Pyrus cerasifera*).—This plant is sometimes used where a spiny hedge is required, but it can hardly be considered as good as the hawthorn for the purpose.

Lawson's Cypress (*Cupressus Lawsoniana*), *Thuya plicata* and *T. orientalis* are evergreen trees which are employed for hedges. These will grow to a good height in a cool, moist soil, but they sometimes become bare at the lower part.

Box (*Buxus sempervirens*).—Where a very low hedge is needed, the box is quite a good subject, but it is of slow growth, except in a moist soil.

Holm Oak (*Quercus ilex*).—This is a splendid subject for the west and south of England and it grows quite well in very exposed positions. The holm oak should be planted carefully in a deeply dug soil or it is quite likely to die. When once established a hedge of holm oak will stand hard clipping and it will then form a very dense growth.

There are many other plants, such as Lonicera nitida, Cupressus macrocarpa Thuya Lobbi, which can all be employed, and any one will be found to serve the purpose equally well.—L. B.

How to Plant a Dry Border.

A DRY, porous border, where the soil is said to be fiery, cannot be planted out in any haphazard fashion because many things will not do in it; with forethought and preliminary preparation it may however, become one of the prettiest features of the garden. First of all let me say something about preparation. Obviously dry soil lacks "body" and a sufficiency of spungy humus to retain enough moisture to keep the plants going. Turfy loam is fine and sometimes better than manure, but, in the main, a fair dressing of good soppy, fairly fresh manure should be preferred. Let it be applied a week before the work of seed sowing and planting out is begun. Failing manure, it will be found that decayed vegetable rubbish, cesspool sludge and weedless ditch cleanings make an excellent humus-giving addition to dig in. The surface thereafter should not be left rough, and at all periods of the growing season it is found that the ideal plan is to keep the surface in a fine tilth by constant hoeing. Given such preparation, and provided that the correct plants are grown, the border will become a perfect blaze of blossom. Nasturtiums do exceedingly well in such a border even when manure is almost or totally absent, and the score of common varieties available enables each grower to make up some pretty schemes. I find that it is quite all right to put the seeds directly into the border in twos, the spot being trampled firm afterwards. Antirrhinums are best sown in autumn, because they form a fine root system during winter and prove superior to spring-planted stuff. Among other annuals which may be sown directly into the border are the several varieties of flax, the glorious eschscholtzias, nemophilas, Virginian stock, Abronia umbellata, etc. Lobelia, zinnias, alyssum, double daisies, geraniums of all kinds and annual carnations can be planted out in May during a spell of damp weather, after which they will bloom profusely. Certain perennials do equally well, but they ought to be raised in nursery beds elsewhere and planted out in autumn. The reason for this is obvious; the soil is more moist at that time and the plants root well before summer puts them to severe test. Where plants are purchased, autumn planting will again be found best. We can but briefly run over a few names—pinks, antirrhinums, arabis, cerastium, sedums of many kinds, house leeks, antennarias, Rose of Sharon (H. calycinum), sun roses, catmint, Californian

FOR FURNISHING RICH AUTUMN COLOUR IN THE ROCK GARDEN THE JAPANESE MAPLES ARE EXCELLENT.

Digitized by Google

fuchsias, sea hollies, santolina, statices, irises, dwarf campanulas and so on.—H. H. A.

Herbaceous Salvias for Border Decoration.

AT this season when so much new planting is being done, greater variety might be given to herbaceous borders by including a few salvias. They are easily grown, not needing any special culture, and can be relied upon to give a good show of flowers in their season. The predominating colour is blue, and for that reason they are particularly valuable. They increase with moderate quickness, and can be propagated by division of the root stock or by sowing seeds. Those of a semi-shrubby nature can be raised from cuttings in the spring.

The most used variety is Salvia argentea, earning its name by having large, woolly foliage of a silvery tone. The flowers are a bluish white in colour and the plant runs to about 2ft. in height. The foliage alone forms a striking contrast to the other occupants of the border. One authority recommends growing this as a biennial and the plants are always at their best during the second year, and a new stock is easily raised from seed.

S. azurea is of a more shrubby nature and runs to about 4ft. in height, but in most places it is likely to be kept herbaceous by the frost. As its name implies, it is of a very pleasing azure blue, and makes a good back row plant, or it is useful in the foreground of a shrubbery.

When quite happy, S. uliginosa will rise to a height of 5ft. or 6ft., and it is truly herbaceous, dying right to the ground in early winter. The flowers are not large, individually, but are borne in long spikes, and are a bright blue in colour.

S. virgata nemorosa, with blue flowers and red bracts, make a good subject for near the front of the border, and it only grows about 2ft. high.

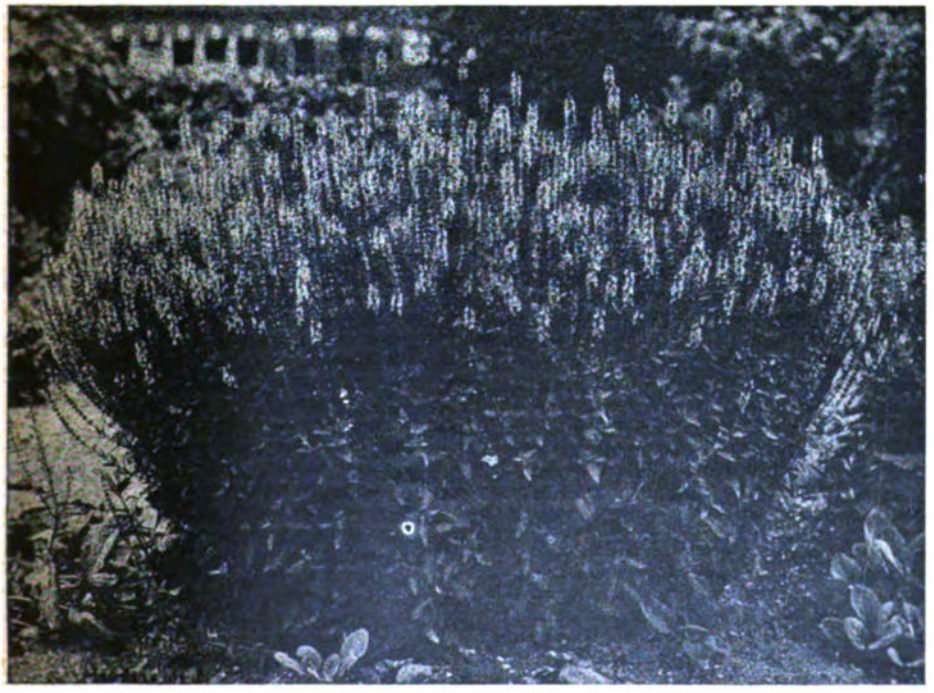
The meadow salvia, S. pratensis Tenori, gives a good display in July and August, growing 2ft. high and having dark green foliage and blue flowers.

There are many other varieties, but between the rareness with which they are offered for sale and the somewhat confused naming, it is useless to mention them. The beautiful S. patens is not forgotten, but it stands almost in a class by itself, and although it does well in the open during the summer, it is safest to lift the roots and store them under cover in the winter.—T. H. W.

A Useful Dwarf Heath.

AMONG dwarf shrubs suitable for the rock garden or any position where a moist peaty soil can be provided are the menziesias, closely allied to the heaths. All the species are of neat growth and bear pretty drooping flowers. Of these the best known is M. polifolia (now usually referred to as Dabœcia polifolia), St. Dabeoc's Heath, which grows to the height of 12ins. to 20ins. The erect flower stems of this plant bear graceful one-sided drooping racemes of handsome crimson purple blooms. The pure white variety is quite as attractive as the type, and there is a pretty form with purple and white flowers, called bicolor. St. Dabeoc's Heath flowers in the summer and will remain in bloom for a considerable time. The plant certainly does best in peat, but it often succeeds well in other soils. M. cœrulea (syn. Bryanthus taxifolius) grows to the height of from 4ins. to 6ins. and has pinkish lilac flowers. A much more beautiful species is found in M. empetriformis, which forms a dwarf, heath-like bush about 6ins. in height and produces clusters of rosy purple bells. This species is really a great acquisition for the rock garden, and it is most happy in a fully exposed situation in a rather moist, sandy, peaty soil. Menziesias may be increased by division of strong tufts, preferably in the spring; other means of propagation are by cuttings about ½–1 in. long placed in sand beneath a hand glass.—L. B.

ST. DABEOC'S HEATH, A USEFUL PLANT THAT FLOURISHES IN MOIST PEATY SOIL IN THE ROCK GARDEN.



SALVIA VIRGATA NEMOROSA MAKES A HANDSOME PLANT FOR THE BORDER.

Making a Lily Pond.

WHERE circumstances permit the work of making a new lily pond should be done now. Next May the lilies should be planted. In the interval the pond can be tested as to its stability and the plants may be studied and duly ordered; also, the necessary turves should be cut and stored.

The first point to consider is the position and the facilities available for draining off the water when this is necessary. The two ways of constructing a lily pond generally followed are stone or brick ponds, or puddled clay ones. Where small ponds are being formed, the brick or stone one is the most suitable. Puddled clay answers very well in the case of large ponds, and especially those that are situated in dells or depressions in meadow or woodland.

The brick and cement-lined pond must be made deep enough to contain sufficient soil and a body of water that will be adequate for the lasting health of the plants.

The bottom should be covered with bricks laid in cement and a single brick wall, all round, will be thick enough, but the walls, also the bottom, should be cemented. Use fresh cement one part to sand three parts, and lay it on quite half an inch thick. The wall should be at least 6ins. higher than the normal level of the soil, and be finished with rock stones irregularly placed. This will allow of an edging border or narrow rockery for ferns or other suitable plants which form a natural surround. Do not leave the pond empty too long, but fill it with water to avoid any cracking. Cover all fresh cement work with sacks in case frost comes.—G. G.

PLANTS FOR THE AMATEUR'S GREENHOUSE

After the construction of a house, dealt with in our last week's issue, comes the problem of how to fill it and what plants to grow in it. In this article are given suggestions on how to stock a greenhouse for a year so that the most will be got from it.

IN a previous article reference was made to the construction of a greenhouse suitable for amateurs, and it is now proposed to consider the stocking of what is hoped will prove a most useful and interesting addition to the garden. Much will depend on the size and whether it is heated or otherwise. A heated greenhouse has many advantages over one not heated, and it is surprising what can be grown in a greenhouse, even if the thermometer is only just kept above freezing-point during a spell of bad weather. For the present I shall assume that the structure is sufficiently heated to keep out frosts, and later I hope to deal with the unheated greenhouse. With a small house it is far wiser for the grower to confine his efforts to a few kinds of plants rather than a miscellaneous collection of flowering and foliage subjects. Individual tastes will finally decide what to grow in the greenhouse; for instance, one friend of mine, a keen amateur gardener, grows perpetual flowering carnations, another specialises in begonias, while a third succeeds with chrysanthemums, followed by roses in pots, and a crop of tomatoes during the summer; and the produce of the trio would be a credit to any large establishment. I am not an advocate of covering the roof with climbers, but if planted discriminately they add to the beauty and interest of the house providing they are not allowed to get out of hand. They need careful training and ought not to get overcrowded. The following will be found satisfactory. A handsome and free flowering subject is Plumbago capensis, and it should be cut well back after flowering. The Glory Pea of Australia, Clianthus puniceus, is a showy plant, which needs a little peat and charcoal added to the soil. Thinning the shoots after flowering is the only pruning required. Cobæa scandens is well known, easily grown and readily raised from seeds, and these remarks also apply to the beautiful Eccremocarpus scaber. The Passion Flower, of which there are several fine forms, smilax, Lapageria rosea and its variety alba, and tropæolums. T. Lobbianum may be had in bloom soon after Christmas if seeds are sown in August, or from cuttings rooted about the same time. The bright and showy Morning Glory, Ipomæa rubro-cœrulea must be included, and from seeds sown in the spring some good examples in six or seven inch pots will be secured before the summer ends. Streptosolon Jamesoni, with its clusters of orange-red flowers, and the white and sweetly scented Mandevilla suaveolens, are both delightful climbers, and so are several of the abutilons.

A GREENHOUSE DISPLAY IN THE MONTH OF APRIL.
Star cinerarias, calceolarias, and Primula malacoides make a fine splash of colour.

In a lean-to greenhouse the back wall should certainly be covered, and any of the above will succeed. With the exception of the Morning Glory and tropæolums, which will thrive in pots, all the climbers are best planted out in a mixture of loam and leaf soil, with ample drainage provided. Two or three climbers will be sufficient for a small greenhouse, otherwise the growth will be too dense for the plants on the stage. Where tomatoes are cultivated, climbers are best left alone.

When we come to furnishing the stages, we have a wealth of material to choose from, but in every instance it is better to grow three or four groups well, rather than attempt a general collection. There is much to be said in favour of carnations, but to be a success the whole of the house should be devoted to these plants. The best plan would be to purchase small specimens in three-inch pots in the spring, and grow them on in five or six inch receptacles to give some good blooms from early autumn onwards. These plants will be kept a second year, they will need repotting about April, and when the pots are filled with roots a teaspoonful of carnation manure every fortnight will add lustre to the foliage and improve the blooms. Red spider is kept down during the summer months by an occasional spray with salt water, two or three ounces to the gallon. Zonal pelargoniums or geraniums constitute a showy and easily grown race, and they can be obtained in great variety. The finest display is seen during the spring and summer months, and a young stock is kept up by rooting a few cuttings annually about August. Odd plants are cut back hard early in March and repotted directly new growth appears. A few of the ivy-leaved varieties, especially C. Turner, should be included, also Heliotrope, for its charming fragrance. Show pelargoniums blossom in spring and early summer, but care must be taken to keep them free from green fly. When the flowering period is over set the plants outside in full sunshine and gradually reduce the water supply. Cut back the shoots to near the old wood in August, and repot three weeks later, shake out all the old soil and use rather small pots. Later on they will be given larger pots, in which they will bloom. Cuttings will readily root in sandy soil in August, if placed on a shelf in the greenhouse.

Tuberous rooted begonias are excellent for the greenhouse; they produce a brilliant display in summer, and die down for the winter, thereby affording space for other subjects that blossom in the dull period of the year. When dormant the tubers can be stored in a dry place, even in the dwelling house, and started into growth about March, by placing them closely together in a box containing an inch or so of leaf-mould and sand. They should be potted up directly growth is evident, using pots which will take the bulbs comfortably. A mixture of loam, leaf-mould and sand will suit them, but light potting must be the rule. There are also many other bulbous plants, such as the amaryllis or hippeastrum, and these plants do not require the amount of heat so often recommended, but they do not flower so early. After flowering they are encouraged to make plenty of growth, when they gradually dry off and take a decided rest. Give little water in the spring till the flower spikes are seen.

Liliums are easily grown, especially L. regale, and the majority will increase in stature if not neglected after blooming. Arum lilies, cyclamen and the Scarborough lily, Vallota purpurea, will also succeed. For late winter and early spring, bulbs will play an important part, especially hyacinths, tulips, narcissus, freesias, lachenalias and Iris tingitana, all of which are potted in August and September, and introduced to the greenhouse when well rooted. Fuchsias, the new hydrangeas and Campanula pyramidalis are sure to give a good account of themselves in the summer. Chrysanthemums must be included to keep up a display in October, November and December; the cuttings are rooted in January and grown on inside until there is little likelihood of frosts, when they are given an open site in the garden. Here they remain till flower buds appear, when it will be necessary to take them inside. A few foliage plants could be included, such as Rex begonias, Grevillea robusta and Asparagus Sprengeri, the latter being available for hanging baskets and furnishing the front of the stage. A greenhouse will be found useful for other plants, such as mustard and cress, early rhubarb under the stage, raising seeds in the spring and ripening off tomatoes which were grown outside. There are other subjects quite suitable, and in the above notes attention

Digitized by Google

has been drawn to a few of the principal groups.

A few alternative suggestions are given in the accompanying table for furnishing the greenhouse, which can be varied to suit the individual.

This gives an idea when the plants may reasonably be expected to bloom. The annuals will be a decided success if seed is sown in August, and the plants grown in a cool atmosphere. Many other selections will occur to the observant and intelligent cultivator.

A few general cultural hints may be helpful. Whenever possible maintain a winter temperature of 45 degrees Fahr., and in summer near 60 degrees, but with sun heat these figures will be exceeded and no harm will accrue, if ample ventilation is provided and the floors sprinkled with water twice each day.

Suggested Schemes to be Carried Out in the Greenhouse at Different Seasons.

A suitable rooting medium consists of fibrous loam three parts and one part leaf-mould, with a sprinkling of sharp sand to keep it porous. This mixture can be improved by a six-inch potful of fine bone-meal and old soot to every barrow load of soil. The repotting will be spread over the year according to the subject, but it is not advisable to cause any root disturbance in winter. Watering is an important factor in the cultivation of pot plants, and whenever in doubt, especially during the autumn and winter months, let the plant wait till the following day. Cleanliness is equally essential, and the house should be fumigated directly any insect pests are seen, the principal enemy being green fly. If these few remarks are borne in mind and put into practice at the suitable seasons, they will prove more than the half-way house towards success.

T. W. BRISCOE.

FRUIT GROWING IN SCOTLAND

Varieties to Select, and How to Plant Them. Useful Hints for all Scottish Amateurs.

IN the course of a lecture delivered before the members of the Glasgow and West of Scotland Horticultural Society a few years before his death, the late Mr. David Storrie described fruit growing in Scotland as a lost art. His remarks referred more particularly to the culture of apples, pears and plums, and condemned the then prevailing system in villa, manse and cottage gardens of growing the trees on walls as a background to a flower or vegetable border without studying their individual requirements. Manure was dug into the soil annually for the benefit of the occupants of the border, and the roots of the fruit trees shared in the general distribution, whether or not it was suited to their needs. Since that time fruit growing in small gardens is more extensively practised, but the rate of progress has been slow owing to a variety of influences which are regarded as a deterrent to success. Unsuitability of climate and soil and the unprotected condition of the modern garden are discouraging factors, so much so that the production of apples, pears and plums has been described as a job for the expert or professional gardener. Irregular or poor crops and the disappointments experienced by neighbours have likewise checked expansion; while the troubles due to insects, diseases, and insecurity from thieves all tell against future expansion. It is an unfortunate defect of the modern housing scheme that the garden boundary neither offers privacy nor protection, and one can hardly blame the owner who, under the circumstances, excludes fruit from the field of practical operations.

In some cases which have come to my knowledge, the grower has been unfortunate in his selection of varieties, and in others the failure of the crop was invariably due to over-pruning, a process that involved the removal of fruit spurs. It is inadvisable for amateurs to attempt the culture of late pears in Scotland, for the vagaries of the climate are such that even the protection of a wall will seldom bring the fruits to full maturity from late September onwards, except in a favoured locality. Attention should, therefore, be confined to one or two early sorts which ripen in August or early September and usually yield an average crop, provided the spring blossom is not subjected to sharp frost. Apple production should also be restricted to varieties that ripen in August and September; but the early class is a numerous one and contains several of the most popular and free-bearing examples.

But there is another reason why discrimination should be exercised in the selection of fruit trees. Scientific investigation has revealed sterility in certain varieties, while others are self-pollinating, and a third class are partly self-fertile. Trees that are self-sterile must, therefore, depend on the pollen of other trees for their fertilisation, and this can only be accomplished by providing a self-pollinating tree in the vicinity of sterile varieties. In this connection there is an important condition that must not be overlooked. To obtain the benefits of cross-pollination the trees must blossom about the same period, otherwise an early sterile apple would receive little or no assistance from a late variety, because the blossoms of the one would be over before the flourish of the other was fully opened. Of course, it might reasonably be argued that a simple solution of the problem lies in the direction of planting only those varieties that are self-pollinating; but if that policy were adopted, the grower would be deprived of several first-class fruits. Cox's Orange Pippin, for example, which has the reputation of being the finest of all dessert apples, is classified among the sterile specimens, and should be planted in the company of a self-pollinating sort such as Worcester Pearmain. In districts where bees are scarce, especially when the weather is cold, it may be expedient that hand pollination be adopted, but that again depends on the form of the tree.

A CHOICE BASKET OF LANE'S PRINCE ALBERT, A GOOD LATE KEEPING APPLE.

The principal forms of fruit trees consist of the cordon, pyramid, bush and standard, any of which are suitable for a small garden. The cordon does not seem to be held in great favour in Scotland except in big private gardens, where pears are grown on a wall; but it is well adapted to the requirements of the amateur who has little space at his command. Cordon trees can be planted 18ins. apart without shading or interfering with low-growing plants in the immediate vicinity. An amateur in a Glasgow suburb, possessed of initiative, planted cordon apple trees on either side of his main walk, and from this avenue he obtains sufficient fruit to supply the requirements of the household all the year round. The bush and pyramid forms are also to be commended as growth can always be kept within reasonable bounds, and, like the cordon, they can be easily pollinated by hand.

Provided the leaves have fallen, the planting of fruit trees may be undertaken about the beginning of November and be continued until the end of December; but February or March will do as well, as root growth seldom commences before spring. While a good loamy marl is best, not only for apples, but for most fruits, ordinary potato ground that has been in cultivation for a short time is a good substitute. In order to ensure the future welfare of the trees, prepare the following compost a day or two prior to planting: 2 parts loam, 1 part leaf-soil, 1 part rotted manure; add a liberal sprinkling of lime, sand and burnt wood ashes, and to every barrow-load mix in a 6in. potful of bone meal. When the hole is dug, put in a layer of the compost at the bottom, and after

Digitized by Google

planting the tree in position spread the roots well out and cover them with a further supply of the compost, which should be carefully worked in among the fibrous growth. Fill up the remaining space with ordinary soil and tread firmly but not too hard. All newly planted trees should be securely staked at the time of planting, as they are apt to rock and disturb the roots during stormy weather. When the operation is complete, mulch the surface with rotted manure, a treatment that is good for all fruit trees. Here are a few useful hints applicable to the general management:

Lime is essential to all stone fruits. If the trees make good wood growth they will benefit by an autumn application.

After a young tree has made summer growth, pinch back the shoots to five or six leaves, and do little winter pruning; merely thin out misplaced shoots.

PEAR LOUISE BONNE OF JERSEY, A GOOD AUTUMN VARIETY.

Lift and transplant single cordon trees in their second or third year so as to check luxurious growth and force them into fruit bearing.

By growing single cordons the number of varieties can be increased.

Half standard trees are preferable to pyramids for growing plums. The former is becoming very popular and has the advantage of a long, clean stem.

Fertility and Conference are good pollinating varieties for pears; Victoria for plums; and Worcester Pearmain and Bramley's Seedling, for apples.

Damsons are not grown so extensively in Scotland as they ought to be. Half standards are preferable to the bush form of tree, as the latter is of rank growth and does not fruit so quickly.

An ideal fruit tree should have each shoot so far apart that when in full leafage every leaf is bathed in sunshine and free air.

Even in good garden soils there is a lack of fertility in fruit trees, due to liberal dressings of nitrogenous manures, or a defective root system, arising from the roots striking deep into the sub-soil. The simplest remedy for trees that are not more than five years old, is to lift each tree when the leaves are beginning to yellow and shorten back all the strong roots, especially those which show a tendency to grow downwards. Replant without delay and add two or three spadefuls of the special compost to accelerate a quick restart.

The following are varieties suitable for culture in Scotland and from which the reader may make a selection:

APPLES.

Ripening August to Early September.

Dessert.—Gladstone, the earliest really good dessert apple; Beauty of Bath, a trifle shy in certain districts; Irish Peach, a delicious early fruit; Devonshire Quarrenden, succeeds in nearly all soils and situations.

Dessert or Culinary.—White Transparent, one of the most reliable; Duchess of Oldenburgh, an attractive summer fruit.

Culinary.—Ernneth Early, the best of the early codlins for crop, vigour and appearance; Lord Grosvenor, one of the most prolific of all apples and does well on a dry soil.

Ripening in September and Early October.

Dessert.—James Grieve, a popular mid-season table fruit; Worcester Pearmain, seldom fails either as a standard or bush form; Rosebery, fertility good, ripens mid-September.

Dessert or Culinary.—Golden Spire, a regular cropper, recommended for small gardens; Cutler Grieve, good for any purpose and seldom misses a crop, even in adverse seasons; Cellini, a regular cropper in most districts and conspicuous for its brilliant colour; Warner's King is a well known mid-season apple, but there are complaints of cankering during the past cold, wet season.

Cooking.—Ecklinville, Stirling Castle, Bramley's Seedling and Lane's Prince Albert.

Dessert varieties later than Allington Pippin and Ellison's Orange seldom ripen satisfactorily.

PEARS.

Williams' Bon Chrétien is now taking the place of Jargonelle in Scotland, being considered the best of the early pears. Louise Bonne of Jersey is a little later, but the most prolific variety is the Hessle, which makes up in quantity for the difference in quality between it and other sorts.

PLUMS.

Early Transparent (dessert), The Czar and Victoria (dessert or culinary), and Early Prolific (cooking).

GOOSEBERRIES.

Yellow.—Early Sulphur, Broom Girl and Yellow Warrington.

White.—Langley Gage, Careless and Whitesmith.

Red.—May Duke, Red Warrington and Whinham's Industry.

Green.—Keepsake and Langley Green.

CURRANTS.

Black.—Edina, Giant Prolific and Boskoop Giant.

Red.—Fay's Prolific, Murie Red and St. Madoes Late.

White.—White Transparent and Versaillaise.

STRAWBERRIES.

Royal Sovereign, The Leader (midsummer) and Elton Pine, the best late variety in Scotland.

RASPBERRIES.

Red.—Bath's Perfection, a reliable early variety which fruits well on a light soil; Mitchell's a favourite market sort.

Yellow.—Yellow Antwerp.

DAMSONS.

Frogmore and Bradley's King.

CHERRIES.

May Duke (July) and Morello (August-September).

HYBRID BERRIES.

The Loganberry, and Laxton Berry.

A BEGINNER'S COLLECTION.

The following selection is recommended for the small garden worked by an amateur: Apples.—Devonshire Quarrenden or James Grieve (dessert); White Transparent or Golden Spire (dessert or culinary); Emmneth Early or Stirling Castle (cooking). Pears.—Williams' Bon Chrétien or Hessle. Plum.—Victoria. Gooseberies.—Early Sulphur (yellow), Whitesmith (white), Keepsake (green), and Whinham's Industry (red). Currants.—Boskoop Giant (black), Fay's Prolific (red), Versaillaise (white). Strawberries.—Royal Sovereign or The Leader. Raspberry.—Bath's Perfection. Cherry.—May Duke. J. Y.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the contributors.

THE HALF GUINEA HINT

Winter Treatment of Scabiosa Caucasica & Lobelia cardinalis.

Before winter sets in it is advisable to give Scabiosa caucasica a little protection around the roots, such as leaf-soil or old bulb fibre. To keep off slugs place a little powdered charcoal or coarse silver sand direct on the crowns. This has been found very effective with choice delphiniums, also rock plants. The roots of Lobelia cardinalis are apt to rot during the winter if not carefully attended to. Pots or pans are better than boxes to store them in, as wood keeps wet and very often a fungoid disease sets in. Place close together in clean leaf-soil and silver sand, and keep in frame or cold greenhouse, but as soon as the stem begins to decay, which is generally towards the end of November, I prefer to put them on a shelf in a slightly heated structure, so that the stem is kept dry, which can be removed as soon as it will part readily from the roots. Very little water is required, just enough to save shrivelling.—F. D.

Economical Fencing for Cordon Fruit Trees.

In small gardens the cost of straining posts for wire fencings for espaliers, cordons, etc., is prohibitive, 12s. 6d. to 15s. each. An economical fencing can be erected as follows: Obtain angle iron standards, 1¼ins. by 1¼ins., 8ft. overall, fitted with earthplates, the L's bored at intervals for bolts, cost 2s. 6d. each. For horizontal members use three or four lines of the 9ft. tubular rods, either ½in. or ¾in. diameter, the latter for choice. These are sold for curtain rods or lawn tennis court surrounds, and have the ends flattened and bored for bolts; they cost from 1s. to 1s. 2d. each. With a little ingenuity and the addition of lighter sections for intermediate posts and Government surplus wire, erections can be made upon which all kinds of fruit trees can be trained.—C. A. W.

Planting a New Hedge.

When planting hedges of Cupressus Lawsoniana, C. macrocarpa, Thuya Lobbi and many other subjects, after the trench has been prepared for planting, drive a stout stake about the height of the plants into the ground at each end of the trench, also at intervals of about 4yds. along the trench. Take a length of stout cord, secure to end stake, and run along the row, putting a couple of turns round each stake, taking care to keep it tight, and secure it to the other end stake. The height of the cord should be about three-quarters of the height of plants when

Digitized by Google

planted. Now plant carefully and tread securely. After planting, tie with soft string the main stem of each plant to the cord. This method prevents plants from rocking in the wind, keeps them in a straight line, perfectly upright, and so assists materially the formation of a good hedge.—G. E. W.

Disposal of Garden Rubbish.

Every autumn most of the cut-down stems of herbaceous plants are relegated to the rubbish heap to be burnt. I find it an excellent practice to tie them in neat bundles like sheaves and when double trenching the ground place them in the bottom trench. The effect is threefold: (1) It assists drainage; (2) it gives off a certain amount of ammonia which is converted into nitrates; (3) it adds humus to the soil, especially if leaves are thrown in with the bundles. By the following season the stems are well decayed, and this method of disposal yields more in manurial value than the bonfire. All woody material, such as rose trimmings, fruit tree prunings, etc., must be burnt.—D. W.

Digging a Circular Flower Bed.

Although digging operations are nowadays fairly well understood, people often make hard work of digging a circular flower bed. A good method is to liken the bed to a clock and take out a trench as from twelve o'clock to the centre where the hands are joined, and dig round clock-wise, taking two spit widths on the outside, slowly shortening till the middle, when just three or four inches are sufficient to keep the trench workable. By this method the digger ends up where he began and his soil from trench is at hand to fill up and complete the operation.—P. P. F.

WHAT OUR READERS SAY

GATHERING LEAVES.

SIR,—As an improvement on your correspondent's hint for gathering leaves, let me suggest that a larger piece of sacking, two or three yards square, be taken, and two adjacent corners be pegged or weighted down, so that the intermediate edge lies close to the ground. Sweep the leaves over this edge direct on to the sacking, gather up the four corners and away. Two barrow-loads of leaves can thus be gathered up in less time than it would take to fill the barrow once with the usual two pieces of board.—FRANK GRAY WALLIS. *Eastham, Cheshire.*

A GOOD POTATO YIELD FROM SEFTON WONDER.

SIR,—The enclosed particulars of the weights lifted from a single root of Sefton Wonder potato in our recent competition would, I think, be of interest to many of your readers interested one way or another in potato cultivation.

Mr. T. Milne, 12, Rainton Road, Elmfield, Doncaster, lifted, on October 1st, the enormous weight of 24lb. 6 oz. from a single root of a new second early immune variety of potato named "Sefton Wonder." Other weights lifted on the same date in different districts were: 22lb. 2 oz., by W. H. Walley, Bank Cottage, Ponsanooth, Perranwell, Cornwall; 20lb. 6 oz. by Mr. R. C. Beard, 2, Railway Cottage, Llanwrtyd Wells; 19lb. 11 oz. by Mr. W. Wood, gardener to Dr. Randle Leigh, Waterloo, Lancs.

Allowing that, in this competition, each plant occupied 1 sq. yd., and taking the average yield to be 20lb. per root, the weight of crop per acre would amount to over 43 tons.—J. LYTLE, *Liverpool.*

[We can also testify as to the excellent crop yielded by this variety this year in our own garden, in a suburb of London, where 14lbs. of seed of Sefton Wonder were sown this spring. The results fully bear out those set forth by our correspondent. In addition we might add that the variety is a good cooker and excellent flavour.—ED.]

PLANTS IN FLOWER IN A DEVON GARDEN.

SIR,—There has been no frost here up to date (November 6th), most unusual. The following is a list of flowers and shrubs still in bloom which may be of interest to your readers: Salvia leucantha, S. Grahami, Bowles Black pansy, Senecio pulcher, Salvia uliginosa, Casaia corymbosa, Hydrangea quercifolia, Gentiana sino-ornata, Schizostylis coccinea, and var. Mrs. Hegarty, Escallonia montevidensis, Diplacus glutinosus var. puniceus, Coronilla glauca, Crinodendron dependens, Prunus Miqueliana var. autumnalis, Abelia Schumanni and Solanum jasminoides.—H. G. HAWKER, *Ermington, South Devon.*

ROSES FOR BEDDING.

SIR,—I read with interest your article in THE GARDEN of October 29th on bedding roses. There were one or two varieties rather new to me, such as Mrs. Fred Howard, Mrs. William Fife and Scarlet Glory, and I missed a few, such as Independence Day—but I suppose you would consider Elphinstone displaces it; Frances Gaunt, which is a great favourite of mine; W. C. Gaunt, a very good bedder, but rather lacking in scent; Henrietta, which, though it grows a bit tall, is, I think, a very good bedder—at least, as good as, say, D. P. Roberts, which it rather resembles in habit, etc. Even if Mrs. Henry Morse and Mrs. George Shawyer *do* mildew, they are worth including in a list of best bedders. Miss Willmott is, I consider, a very fine bedder. Have you seen the bed of this variety at Kew? The man who looks after it there seems to understand its requirements more than most people, as he gets it to grow quite rampant. A rose that does very well with me is Ruth—an uncommon rose altogether. As long as singles were included, Irish Fireflame, I think, has a claim as a bedder. It is rather rampant, but not much more so than Isobel.

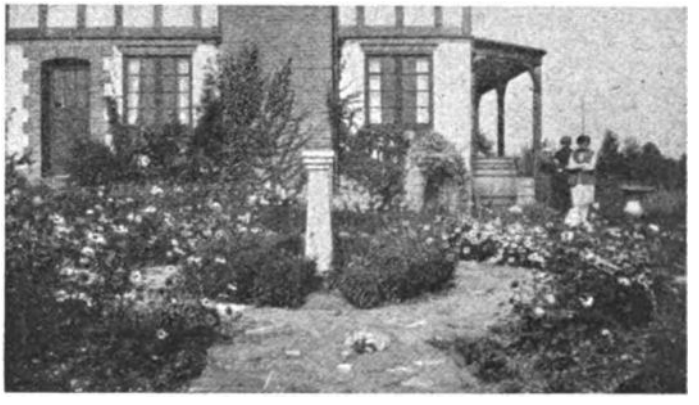
Another rose I like is A. M. Rouyer; I do not know if Souvenir de Mme. Boullet is like it—if it is an improved Hillingdon, perhaps it is.

I do not expect you to reply to all this in detail, as, no doubt, soil and conditions may be the cause of these fancied differences.—J. L., *Shipston-on-Stour.*

[Our correspondent's letter was forwarded to Mr. G. M. Taylor who sends the following reply: "Scarlet Glory, Mrs. Fred Howard and Mrs. William Fife have now been grown long enough to warrant the statement that they are improvements upon anything now grown, and that they are well worthy of inclusion in a collection of roses, no matter how small it may be. I consider Lady Elphinstone a better all-round rose than Independence Day. If you like Frances Gaunt you will like Mrs. Fred Howard. I think the latter displaces the former. Why bother with W. C. Gaunt now, when you have such a sweetly scented thing as Etoile de Hollande? The general complaint against Henrietta, and I agree, is that the colour fades badly. Mrs. Henry Morse and Mrs. George Shawyer are good roses, but they are susceptible to mildew. People have no room nowadays for such sorts. You can easily dispense with the two and never miss them from the garden to-day. I quite agree with you about Miss Willmott, but it is not a rose for everyone, hence the reason for not including it in my list. I put Isobel in the list because it is such a favourite, easily, I think, the greatest favourite among the singles. Fireflame varies too much in colour to find a place with the elect. Aspirant Marcel Rouyer is a fine rose, but, alas! too variable in colour to be recommended generally. Souvenir de Mme. Boullet is, virtually, an improved Lady Hillingdon."—ED.]

AN ATTRACTIVE FRONT GARDEN.

SIR,—The accompanying illustration of a garden at Chipstead in Surrey may prove of interest to a few of your readers. It shows how a corner of a garden may be made attractive by skilful planning and planting. Use has been made of a sundial as a central feature, with crazy paved paths radiating from it. Small beds are planted up with a variety of summer and autumn flowering plants, which despite the wet summer have given a bright display. The Michaelmas daisies in particular made for striking colour effects.—A. W., *Grafton Rotherfield.*



AN ATTRACTIVE CORNER IN A FRONT GARDEN.

THE YELLOW COSMEA.

SIR,—I have grown this particular cosmea for two or three years and consider it rather hardier than the other coloured forms. More than that, it is very much freer flowering. Possibly some may consider the shade of yellow too garish, but planting in open surroundings will do much to make void any such first impression. Its colour may be well described as a deep sunflower yellow. The foliage is a deep green, more so than that of the other coloured types, and very finely cut. As a cut flower it lasts well in water, while the plants continue blooming splendidly until cut down by the frost. Plants will grow upwards of 2ft., and when smothered in star-shaped yellow blossoms make a truly showy bed or border. On reasonably light soil I find there is no reason to transplant this half-hardy annual; it will germinate and grow sown outdoors where it can remain undisturbed. Now, past mid-October, this miniature yellow cosmea is full of flowers.—C. T.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

AS in all other garden work, there is a right way and a wrong way of digging the ground. It is such a simple operation that advice on the subject may seem superfluous, but one has only to compare the methods of the workmen usually employed by jobbing gardeners and the way of the amateur who digs his own soil and note the difference in their procedure.

How to Dig Correctly.

The object of the former seems to be determined by the least possible effort, and to accomplish this the spade is manipulated at such an angle or slope that it only penetrates the soil to the depth of a few inches, leaving portions of the manure exposed on the surface. The advantages of deep cultivation are seldom recognised and weeds are treated in the most haphazard fashion. Now, as the object of digging is to turn over and clean the ground that is to be cultivated, it always repays the gardener for the extra time and trouble involved to do the work thoroughly. Hold the spade as nearly perpendicular as possible and force it straight down into the ground, so that the soil to the full depth of the metal will be broken and turned over. Preparatory to starting operations, clear the ground of all surface weeds, while deep rooted perennial weeds should be removed as they are exposed. If manure is to be dug in, avoid the system of scattering the material over the surface, as it is difficult to lift soil and manure together on the spade and transpose the latter at a depth which will not come in contact with the roots of newly planted subjects. Begin by taking out a narrow trench, representing the full depth and width of the spade, and deposit the soil at the other end of the border or plot. Scatter the manure in the bottom of the trench with a fork, and in filling up the space with successive spades of earth, a new trench is formed and the procedure repeated and deeper cultivation assured. Do not attempt making the surface uniform and fine by raking; leave it in a rough condition over winter, and by the time the sowing and planting season comes round the soil may easily be made friable by breaking down the lumps in the process of raking.

When to Dig.

Never endeavour to dig your garden when the soil is in a pasty condition and adheres to the spade. Even in dry weather, heavy or clay land, which is common in Scotland, is difficult to till, as the soil forms into solid clods which break down readily after being exposed to the elements. The texture may be further improved by digging in coal ashes and strawy manure from the stable. On the other hand, the treatment of light or sandy soil is a comparatively easy proposition. While mediums of that description may be forked over at this season, digging and manuring should be postponed until spring, when cow or pig manure, decomposed vegetable matter or other form of humus should be incorporated in liberal quantities.

Treatment of Autumn Sown Sweet Peas.

Sweet peas sown in late September and early October and germinated under glass are apt to become drawn unless they receive cool treatment in a frame. To obtain strong bushy plants in spring pinch the main stem of the seedlings when two pair of leaves have developed. This treatment will cause the side shoots to break, but progress from now onwards will be slow, as development during winter partakes more of the formation of the root system than the growth of the plant above ground. The seedlings should be provided with plenty of air, but the removal of the sashes in fine weather exposes the young and tender foliage to the depredations of the feathered tribe, consequently protection in the form of close meshed wire netting placed over the frame is advisable as a precautionary measure. Slugs, too, are troublesome and their destruction involves systematic inspection, and wherever the presence of mice is suspected one or two traps are usually successful in capturing the vermin, which are capable of inflicting a great amount of injury in a single night. Seedlings in boxes should be transplanted singly into 3in. pots, because, if they are allowed to remain as at present the roots frequently become a tangled mass, which is not easily unravelled without inflicting injury.

Lobelias from Cuttings.

The propagation of lobelia from cuttings is an easy method of producing stocks of that popular edging plant, which, if treated in that way, comes into flower from two to three weeks earlier than plants raised from seed. A few of the old plants should now be potted up and accommodated in a frame or greenhouse where they can be protected from frost, and care must also be taken that they do not succumb to damp. In a short time new shoots make their appearance. When large enough to handle, these should be taken off and planted in boxes of light soil and grown on until they can be safely transferred to their flowering positions in the open bed or border.

Bringing in Bulbs for Christmas.

Early planted bulbs that are wanted for Christmas bloom should now be in a state of growth to warrant their removal from beds of ashes to partial shade indoors. If a greenhouse is available, place the boxes under the staging for a few days until the foliage assumes its natural green colour, when the foliage may be exposed to the full light and endeavour to bring them into flower under cool conditions or moderate heat. Bulbs, that were planted in bowls of fibre in September, and have been standing in the dark, will can be showing good top growth and now be subjected to the warm atmosphere of a living-room. Water may be given more freely, but, while the fibre requires to be thoroughly saturated, stagnant water should not be allowed to accumulate at the bottom of the bowl.

While rhododendrons may be transplanted any time from now until spring, it is advisable, in view of the scarcity of stocks, emphasised in the trade catalogues which have recently been issued, that orders should be placed early rather than later in the season, and should it happen that the site is not yet available for the reception of the plants an endeavour should be made to stipulate the period of delivery. Owing to their close, fibrous root system and the customary method of surrounding it with a good ball of earth, rhododendrons are seldom affected by the change; nevertheless, prudence dictates that the site should be prepared beforehand and made fairly rich in humus by the addition of non-calcarious substances, such as peat, leaf-soil, or well rotted manure. Indeed, there is no better planting medium with which to surround the roots than a compost of peat, decayed leaf-mould and sand. There are many really good hybrids in the various colour classes, but the following representative collection may be helpful to readers who desire a few meritorious and moderately priced sorts: White—Baroness Henry Schroder Mrs. Tom Agnew (lemon blotch), and Sappho. Pink—Princess Juliana, Pink Pearl and Miss H. de Trafford. Rose—Lady Armstrong, Mrs. Chas. Sargent and Rosabel. Crimson—Comte de Gomer, Broughtonii and Michael Waterer. Purple — Joseph Whitworth, Chas. Thorold and Chas. Bagley. Salmon and yellow—Mrs. Holford, Mrs. F. Hankey and Smithii aureum. ST. MUNGO.

FRUIT AND KITCHEN GARDEN

How to Make a Hotbed.

FRESH manure heaped up will always produce heat, but unless the material is arranged in the right way the warmth will not be lasting. Every gardener should master the business of making an efficient hotbed, for the device will be found one of the most useful aids in the culture of plants. On a hotbed crops of vegetables and salads may be raised at all seasons of the year, while the growth of many plants can be advanced. The work of forming a hotbed is really divided into three stages.

Preparation of Manure.

First of all one may deal with the preparation of the manure. The best substance for making a hotbed is, without doubt, stable manure; but such material as grass, fresh leaves, etc., can be employed. It may be pointed out that with the latter substances the heat is more violent but nothing like so lasting. Many gardeners find it an economy to mix the manure with grass or leaves. Make sure that the mixing is very thorough and on no account should the mass be exposed to rain. The fresher the manure is the better, and when secured it should be at once stacked under shelter. Each day turn it well about in conjunction with the other substances until there is little steam and practically no unpleasant odour. When turning over the heap, stack it loosely and work out any lumps that are found. If towards the end of the time the heap becomes rather dry it may be slightly moistened with water, but on no account should it be made really wet. Ten days is not too long a time to allow for this preparatory stage, or sweetening process as it is called. A thorough preparation of the manure in the manner described will prove beneficial when the hotbed is brought into use.

Selection of Position and Making of Bed.

When the material is ready select a part of the garden for the bed. A raised, dry position which is exposed to the south and sheltered from cold winds is the best. Successful hotbeds can, however, be formed in situations that are much less favourable. At times the manure is simply packed in the bottom of a deep frame with a thin layer of soil on the surface. Another way is to build the hotbed and then place the frame on the top. If the latter method is adopted, pile the hotbed the same shape as the frame, and about 18ins. wider and longer. The sides should be perpendicular and nearly finished off, and it is an advantage to stack turf round the outside. Pack the manure tightly and after each 6in. layer beat it well down. The deeper the hotbed the greater and the more lasting will be the heat. The most satisfactory hot bed is that in which the heating material is 3ft. or 4ft. in depth. When the hotbed is made place the lights on the frame, leaving these just a few inches open to permit of the escape of steam.

After the formation of the hotbed in the manner described the heat will begin to increase. As long as the heat is increasing the bed must not be used, and to find out when the heat is on the decline the bed must be tested. A simple plan is to push a stick to the centre of the bed and test it at the same time each day. It

Digitized by Google

Continued from page 756.

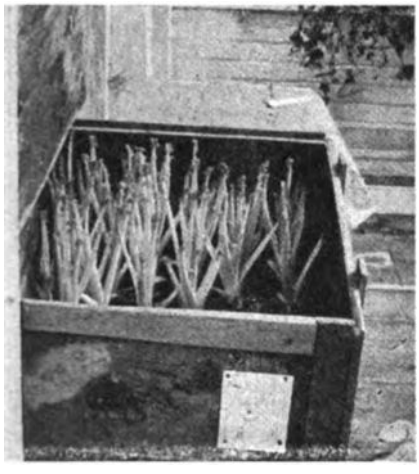
is more reliable to use a thermometer, thrusting this down into a hole which reaches to the centre of the heap. When the stick can be held comfortably in the hand, or the thermometer shows that the heat is on the downgrade, the hotbed may then be used for any purpose. The soil on the top should be from 3ins. to 6ins. thick.

A hotbed made properly will retain its heat for six or eight weeks during the winter or early spring. If the heat begins to decline before the work in hand has been accomplished bank up manure quite fresh from the stable on the outside. The more material that can be applied the greater will be the amount of heat given out by the stimulated bed. These linings, as they are called, are extremely useful in the case of a hotbed formed in winter or where a continuous strong heat is required.

After the hotbed has lost its heat the material of which it was built will be useful for all manner of purposes about the garden, as it has a high fertilising value.—L. B.

Forcing Seakale.

THERE are two commonly adopted ways of forcing seakale. The simplest method is to cover the plants in the open ground with pots, boxes, leaves or stable litter. It



SEAKALE FORCED IN AN ORDINARY PACKING CASE WITH THE LID MADE LIGHTPROOF.

is a mistake to use too much manure, as the heat will then be excessive and it is quite likely that the seakale will have an earthy taste. Plants grown in this way will yield for several years, but the soil should be of a light, sandy and well manured character. Moreover, each spring the ground should have a dressing of a good artificial manure. The original seakale plants are raised from seeds sown in March, the seedlings being ultimately thinned out to a foot or eighteen inches apart. The plants should be allowed to grow for two years before any attempt to grow them in darkness is made. Although somewhat more trouble is involved, a much better way of forcing seakale is to take up the roots in the autumn and force them in succession, as required, in some heated structure. It is well to lift all the roots which it is intended to force and to place them in a thick layer against a north wall or in any exposed position. This will help to ripen the roots and they will then force all the better. Remove all small roots and shoots from the pieces which it is proposed to force. If these are covered with loose litter until the spring, and then planted in rows 18ins. apart and 12ins. apart in the rows, they will in course of time develop into strong crowns, which can be forced. Any place that is quite dark will be suitable for forcing seakale. The roots are packed in boxes with light soil, leaves, or refuse from an old mushroom bed, a few inches being allowed between the crowns to allow of a free development. Quite good crops of seakale may be grown in a cellar and, of course, where anything like a darkened hot-bed or forcing pit is available the results are all the better. It may be pointed out that the temperature should not exceed 55 degrees Fahr., and even if the figure is somewhat below this the crop will be ready in from five to eight weeks.—S. L. B.

Manuring Fruit Trees.

TO enable fruit trees to bear good crops regularly, manuring must be given due consideration. But discrimination in the choice of manures is necessary or the result may be quite the opposite to that desired. Farmyard manure and bulky substances of a similar nature, are excellent for promoting growth, and trees that have become somewhat stunted benefit from their use, but those of normal vigour would be encouraged to make rank, unfruitful growth by the too frequent applications of these manures, especially if the trees were comparatively young. What is needed in their case is a fertiliser that will assist, primarily, in the development of flowers and fruit, and a phosphatic fertiliser is of the highest value in this respect. Basic slag is one of the most valuable manures of the kind mentioned, and as it is slow in action, it is necessary to apply it in winter if the greatest benefit is to be derived during the period of growth. From 4ozs. to 6ozs. per square yard is an adequate dressing. Farmyard manure applied once in three years will, usually, prove sufficient for trees of average vigour, that is when about 1ft. of growth is made annually. Trees of considerable size, with a mass of fruit spurs, which are unproductive, benefit from generous manuring and the reduction of the fruiting spurs. Younger trees in a similar condition may be treated more drastically by cutting the branches hard back with the object of inducing fresh growth below the spurs. With liberal dressings of organic manures and attention to soil cultivation, they may then be brought back to a condition of normal vigour.—J. C.

Early Peas.

I WOULD like to warn cultivators who have not had any experience with autumn sown peas, against sowing any seeds in cold, clayey soils in exposed positions. It is a waste of time and seeds to sow them in such soils. But there are many warm borders and the deep, light soils in them are ideal for the early pea crop. The position should be one facing due south, south-east or south-west, and the shelter should be on the north and east sides. If the border has a natural slope to the south so much the better. Take out soil to form a shallow trench, put in some rotted manure and leaf-soil, mixed and in equal quantities or nearly so. Dig in the mixture leaving the surface of the soil in the trench almost level with the soil of the border. Moisten the seeds, roll them in red lead and sow them evenly about 1in. apart. They may be sown a little closer now than is advisable in spring and early summer time. Cover the seeds 2ins. deep and finish this part of the work by placing a layer of sifted ashes on the covering soil. The red lead will preserve the seeds from birds and rats and the ashes the young, tender plants, as they break through the soil, from slugs. Sow the round-seeded varieties only, as the wrinkled ones decay in the soil more readily. Tiny branching sticks should be placed to the rows directly the seeds are covered and these small sticks will not only support the young plants, but will form some protection from wind and frost.—HANTS.

SERVICE BUREAU.—*continued.*

Planting Out Hydrangeas.

I have a number of two and three year old hydrangea plants, which have now grown too large for their pots and I wish to plant them out in a border, facing south. Will you please tell me which is the best time to do this?—F. Q., Thornton Heath.

Keep your hydrangea plants as cool as possible in the greenhouse and do not subject them to artificial heat, nor to frost, throughout the winter and plant them out next April.

Roses for a Low Wall.

I wish to grow roses, of good colour (some shade of red preferably) and scented, on trelliswork placed against a west wall. The wall is low and the ground loamy. Will you kindly assist me by suggesting a few suitable kinds?—W. D., East Minster, Sheerness.

You probably require some climbing tea or hybrid tea roses for your fence, as Wichuraianas would be too vigorous. Some good varieties for your purpose are:—Climbing Chateau de Clos Vougeot, dark red; Climbing General McArthur, red; Climbing Richmond, red; Climbing Mme. Ed. Herriot; Climbing Irish Fireflame, orange-crimson; Climbing Mrs. Herbert Stevens, snow white.

Replanting Lily of the Valley.

My lily of the valley bed has not flowered at all well this year—it is a very old bed—and the soil is lime and chalk. I have top-dressed it with leaf-mould. Will you advise me if I had better take the lilies up and replant, and when is the best time to do it?—E. C., Winchester.

A bed of lily of the valley can be made up at the present time. Choose well drained soil in a partially shaded position under a north or west wall. There should be plenty of air overhead. Place the crowns 2ins. to 3ins. apart, having first deeply dug the soil and worked in plenty of rotted manure and leaf-mould.

Plants for a Cold Greenhouse.

I should be glad of your advice on what to grow in my greenhouse. There is no heating laid on, the only heat possible being from a door leading from a room which will probably have a fire in every day. I am desirous of growing something in the flower line, and possibly later on a few tomatoes.—H. P., Cowes, I.O.W.

You should be able to grow quite a variety of plants in your greenhouse. To start with you could plant a few bulbs for spring flowering, such as narcissus, tulips and hyacinths. Freesias and ixias may also be successfully grown in a cool house. During the summer you could grow zonal pelargoniums (geraniums), fuchsias and tuberous rooted begonias. For autumn and winter flowering you might try chrysanthemums, selecting some of the dwarfer growing varieties for this purpose. There are a number of primulas that should answer your purpose, including PP. malacoides, obconica, kewensis, and also the many varieties of Chinese primulas, the stellata forms being specially useful. Cyclamens in their many beautiful varieties also succeed in a cool house. Calceolarias are easily grown from seed and do well under cool conditions. There are also a number of ferns, such as adiantums and pteris, which are excellent for such a house. You should start with a limited variety of plants and gradually add to them as you gain experience. If you could visit some greenhouses in your neighbourhood, it would be a great help, as you would be likely to see a variety of plants and gain much useful information.

THE CHRYSANTHEMUM SHOW

THERE was a record attendance at the annual show of the National Chrysanthemum Society at the Royal Horticultural Hall, Westminster, on November 3rd and 4th last. Throughout most of the afternoon of the first day the hall was so uncomfortably crowded that it was only with difficulty that the flowers could be seen. But for the most part, the blooms were so beautiful that enthusiasts said it was well worth the struggle. In many of the classes the exhibits reached a high standard of excellence and illustrated cultural skill of the highest order.

The large Japanese varieties fully retain their popularity with the exhibitor, and these were the chief feature of the show. It is just a hundred years since Captain Bernet raised the first European seedling chrysanthemum at Toulouse. At that time there were just under fifty varieties in cultivation in this country and, although these and the Toulouse seedling were the "large-flowered" varieties of their day, they would bear no comparison with the immense exhibition varieties that are now grown. Nor were they of the same type, for it was a quarter of a century later that Robert Fortune sent home from China the first Japanese varieties. Since those days an enormous number of seedlings have been raised by our growers, to the great improvement of the flower. Each year sees the birth of very many new seedlings and, in most cases, it also sees their death, for while many are raised, few are chosen. At the show under notice the Floral Committee of the National Chrysanthemum Society considered the merits of thirty-five of the novelties and gave awards to six of them. Of these six selected ones almost certainly two will never gain popular favour.

But, to return to the show itself. The chief honours fell to Captain R. B. Brassey, of Cottesbrooke Hall, Northampton, who showed thirty-six magnificent Japanese blooms in vases. The blooms of the white Victory were considered to be the finest in the whole show, and the other varieties were Julie, Rosemary Simmonds, Mrs. B. Carpenter, Mrs. A. Holden, Golden Rigby, Norman Chittenden, Duchess of Westminster, Mrs. P. Murray, Mrs. J. Gibson, Majestic and Mrs. Gilbert Drabble. Sir John Ward, K.C.V.O., of Chilton, Hungerford, also had a superb exhibit, and this was of thirty-six exhibition blooms shown on boards. The standard show boards were far too small for the full display of these splendid blooms, which were cramped for space. Among his many good sorts he included Mrs. F. Sleck, Tom Abbot, Victory, Mrs. Gilbert Drabble, Julia and Red Majestic. It was interesting and instructive to turn from these standard show boards, where the flowers were so cramped, to the experimental class, in which the Society provided larger boards. In these a space of 10ins. from flower to flower was provided and the result was admirable. With greater freedom each bloom stood clear of its neighbours and the full beauty could be enjoyed. The Dowager Lady Annaly, Holderby House, Northampton, won the first prize with splendid specimens of such varieties as Autumn Tints, Majestic, Julia, Marjorie Woolman, Melody and Mrs. E. A. Tickle. Other prize winners with large Japanese varieties in these open amateur classes included Viscount Hambledon, Greenlands, Henley-on-Thames; Mr. R. L. V. Sherwood, St. Gatien House, Newmarket; and Mr. F. C. Stoop, West Hall, Byfleet.

The several classes for a vase each of three blooms of specified colours showed which varieties the exhibitors and judges considered to be the best. Mrs. Harold Wells was the best white—it displaced Queen Mary and Victory of former years. Princess Mary was shown by the leading four of five exhibitors in the class for a yellow variety, and Mrs. George Monro, Junr., was equally favoured in the class for any crimson Japanese variety. In the class for a vase of any other colour, Red Majestic was placed first, with Majestic second.

There was something of a mild revival with the old-time incurved chrysanthemum, and in his first prize vases of this type Mr. S. W. Wickens, of Southsea, demonstrated most ably that they have considerable decorative value. His blooms of Captain Kettle, Ondine, Golden Glory and Romance were very attractive.

It may be that the season was too late for growers of what may be termed the fancy types to show any blooms, for there were no entries of pompons, anemone or anemone singles. We missed the graceful little pompon chrysanthemums which Mr. W. J. Hussey used to bring from Exeter. That this dainty type has fascinations was fully evident from the attention and admiration given to the vases shown by Mr. H. J. Jones and Messrs. W. J. Cole and Son in their trade displays. The best varieties were Victorine, orange shaded with ruby; Mary Pickford, the tiniest pure white; Lilian Doty, pink; and Bright Eyes, rose pink.

For some reason, not readily apparent, the singles always require an earlier season than the larger Japanese and the incurved varieties, and in this late season the exhibits of this type were fewer than in an average year. But the quality was fully equal to the general high standard of the show. Viscount Hambledon, who won the George Monro Challenge Cup in the open section, had twelve splendid vases of large singles in such sorts as Augusta, Sandown Radiance, Phyllis Cooper, Supreme and Bronze Molly. In the class for nine vases of the same type, Mr. F. C. Stoop, was first prize winner with excellent flowers of Eaton Scarlet, Susan, Crimson King, White Model and Phyllis Cooper. Although they possess considerable decorative value and great lasting properties, the small singles do not appeal so much to the exhibitor. The best exhibit was that of the pink Florrie King, shown by Mr. A. E. Taylor, Winchester.

The floral decorations were especially attractive and well illustrated the great decorative value of the chrysanthemum, though it was the large-flowered sorts that made the best displays. In these classes the use of any suitable foliage was permitted, so that the flowers were arranged with autumn foliage, Asparagus Sprengeri and similar plants. Miss M. Hodges, Sydenham, and Mr. G. Richardson, Tulse Hill, were the most successful exhibitors.

As ever the large trade displays were a great feature of the exhibition. Mr. H. J. Jones, who received the only large gold medal, had a magnificent group arranged with great taste. In addition to many large vases of the best exhibition varieties, he had some delightful colour schemes with chrysanthemums. These included a primrose coloured seedling and the purple Mrs. E. W. Hayes; In Memorian and E. Reeves; White Ball, a tiny incurved; and Fifi, a beautiful pink variety, grown as undisbudded sprays; and the yellow and buff varieties of Rayonante. Among the singles were Absolute, Crimson Dawn, West Hall, Gem and Oaklands.

Small gold medals were awarded to Messrs. Cragg, Harison and Cragg for a delightful collection of the best market varieties, among which were Jean Pattison, rich bronze; Iolanthe, pale pink; Mrs. F. R. Felton, deep crimson; and Atalanta, rich pink; to Messrs. Keith Luxford and Co., who showed many large-flowered varieties of value, a collection of hardy sorts and a couple of attractive anemone singles. The last named were Thora, of mauve colour, and Winsome, of bright crimson colour, with a gold and crimson centre; to Mr. H. Woolman, for a goodly group of representative varieties; and to Lady Macnaghten, Sandhurst Lodge, Berks, who sent many especially well grown specimen plants. These were from cuttings inserted during the second week of last December, and they carried a large number of decorative flowers. On a shapely plant of the White Blanche Poitevine it was said there were one hundred and fifty-six flowers.

Silver-gilt medals were awarded to Mr. A. G. Vinten, for a collection of market varieties, and to the King's Acre Nursery Co. for a large group of the various types. Mr. Wm. Yandell had a large silver medal for his interesting exhibit of undisbudded varieties and silver medals were awarded to Messrs. W. Wells and Co. and Mr. H. Clark for groups of general chrysanthemums, and to Captain A. H. B. Wright, The Rookery, Marlow, for a splendid specimen plant of the brightly coloured Mrs. R. Luxford.

NEW CHRYSANTHEMUMS.

MONUMENT.—A splendid incurved Japanese bloom made up of broad milk white florets. The flower was broad and deep and of the best exhibition type. First class certificate. Shown by Messrs. Keith Luxford and Co.

MRS. KEITH LUXFORD.—A bright reddish chestnut exhibition Japanese variety which has long drooping florets with golden reverses. First class certificate. Shown by Messrs. Keith Luxford and Co.

BLACKPOOL.—A splendid exhibition Japanese bloom. The florets are of rich crimson colour, lightly touched with maroon and they have golden reverses. First class certificate. Shown by Mr. H. Woolman.

SOUTHAMPTON.—Another excellent large Japanese variety. The long, broad, yellow florets curl gracefully at the tips. First class certificate. Shown by Mr. H. Woolman.

EDITH SEYMOUR.—A light chestnut exhibition Japanese variety. The long, drooping florets have golden reverses. First class certificate. Shown by Captain J. Dalgety, Lockersley Hall, Romsey.

CHARLES DAVIS.—This is an excellent, bright yellow exhibition Japanese variety. The long narrow florets are prettily twisted at the tips. First class certificate. Shown by Mr. H. J. Jones.

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2921 Saturday, November 26th, 1927 Price TWOPENCE

THE Barberries undoubtedly stand in the first rank of our ornamental shrubs not only by reason of their spring beauty, but also on account of their rich effects in autumn. The majority of the species have handsome foliage which assumes the most brilliant autumnal tints, and bear abundant crops of red or blue berries. In spring they are most attractive with a profusion of bright yellow flowers which wreathe the shoots from end to end. As a family they have many fine qualities to commend them.

THE GARDEN

VOL. XCI.—NO. 2921. NOVEMBER 26, 1927. PRICE TWOPENCE.

THE PSYCHOLOGY OF THE GARDEN

TO the observant eye and thoughtful mind life and nature in the garden is a fascinating study, and the charm of the subject is emphasised when it is discussed with the sympathetic and literary touch which characterised Mr. A. W. Brown's lecture on the "Psychology of the Garden," at Edinburgh a few weeks ago. While the practical side of things did not come within the field of observation, the subject was treated in its broadest and finest sense and, as the garden of nature has no limitations or boundary walls, the speaker wandered at will along the main avenues into many sidepaths that were rendered attractive by the presence of bees and birds and flowers. In that interesting ramble round the garden, Mr. Brown drew inspiration from Nature's ample lap and commented in poetic language of the many interesting things to be found there. Light and shade flitted alternately across the moving picture and the common enemies of the gardener were treated in such a way that they did not seem out of place in the artist's conception of Nature. There are critics who may regard such views as idealistic rather than realistic, but the true valuator will assess them as the expressions of a thoughtful gardener who finds pleasure and relaxation among his flowers. The real possession of a garden can best be interpreted as enjoyment, and in this sense the visitor and the random passer-by shares it with you, and may be even the larger shareholder if possession is measured by the foot rule of appreciation.

The following are some of the many good points touched upon in the lecture:

You possess a garden so that you may have pleasure in its beauty, but do not forget the wider enjoyment of sharing it with others, for it can bring no real happiness if you keep the gate shut.

It is not sufficient that you walk around and admire its beauty; you must work in it, exercise your ingenuity, put some of your personality into it and not leave all to the hired man. Do not heed although you make mistakes; we learn and grow wiser from the knowledge of our failures as well as from our successes.

What can be more restful or make us realise more and more the wonder Nature so freely displays to us than a walk round the garden, not merely with our eyes open to admire the many forms and colourings of the flowers, but our minds open to ponder and muse among the annual miracle of their birth while we watch the gradual unfolding of leaf and flower.

There are many plants which, if exterminated, would mean the death of a whole race of insects dependent upon them for food, and, on the other hand, for lack of certain insects, specially fitted to pollinate their flowers, whole species of plants would either disappear or would have to modify their flowers to make them attractive to other forms of insect life.

It is all a finely balanced scheme of give and take. Flowers are not made so beautiful nor are their forms so varied for our admiration alone, unless where nature is interfered with. The main object of their gorgeous colours and beautiful forms is the attraction of insects for the purposes of pollination.

What a voyage of discovery one can launch out upon even within the bounds of a garden: the flowers, the countries they come from and their histories; the birds and the insects, what fascinating life stories some of them have, more extraordinary than the most fantastic fairy tale ever written.

Birds brighten life for us more, perhaps, than we are aware of. Many of us would rather lose some fruit than miss the pleasure of listening to the song of a thrush in the quiet of a summer evening, or the joy of hearing the call of the chaffinch at sunrise; aye, or even the noisy chatterings of the sparrows (Philistines though they be) as they preen themselves on the window sill.

Our garden is a place in which, be it ever so small, there is a deal to love, a deal to admire, and a great deal to learn. Only those of courage and cheerfulness can grow flowers—the courage of overcoming difficulties and the cheerfulness which can laugh at failures. Flowers in themselves are cheerful things and you cannot grow them without partaking of their spirit.

The Apple-Shaped Cucumber.

AT the November meeting of the Royal Caledonian Horticultural Society, Messrs. Scarlett, Edinburgh, exhibited specimens of apple-shaped cucumbers which had been grown during the past two years from seed obtained in Australia. The size and colour of the fruit has no resemblance to the ordinary type of cucumber, while a further distinctive quality is its delicate flavour. Moreover, it is easily digested and may be eaten in the same way as an apple.

This novel species of cucumber has to be grown in a warm temperature and fruits best on the lateral growths, as only male flowers are produced on the main stem. In a season like what has been experienced the plants require to be fertilised in the same way as melons.

The Edinburgh firm are endeavouring to raise a green-coloured variety, as the golden-coloured fruits do not sell so well. Once the new form of cucumber is known it will probably become very popular.

This Week's Work

For Gardens in the South and Midlands.

Protect with ashes kniphofias, delphiniums and other herbaceous plants.

Plant roses and flowering shrubs if weather suitable.

Pot early-flowering gladioli.

Remove bulbs in bowls from plunging ground and expose gradually to light.

Lift seakale for forcing.

Make a sowing of culinary peas on a warm, sheltered border.

Prune peach trees and nectarines on walls.

Cut back greenhouse chrysanthemums that have finished flowering and stand the pots in a frostproof frame.

This Week's Work

For Gardens in Scotland and the North.

Lift and dry montbretia roots.

Cover crowns of herbaceous plants with ashes or sand.

Continue the planting of roses.

Pot up Scabiosa caucasica and winter in cold frame.

Sow seed of delphiniums under glass.

Lift and box Lobelia cardinalis.

Divide astilbes and spiræas.

Complete late planting of early and May-flowering tulips.

Lime vacant ground as required.

Prepare compost for planting.

Oil lawn mower and other garden tools.

Propagate achilleas by division.

Digitized by Google

SHRUBS FOR AUTUMN COLOUR

The shrubbery should never be allowed to become dull and uninteresting during the autumn months. The following article suggests a few good plants whose foliage turns to the richest autumn tints, and which bear a profusion of attractive fruits. A few such dual purpose shrubs, for flower in spring and fruit and leaf colour in autumn, should be included in every garden.

THE dead season during the late autumn and winter months finds many gardens entirely lacking in interest. There is no excuse for this nowadays when we consider the number of fine shrubs and trees that are kind enough not only to provide us with their wonderful autumn-tinted leaves, but carry brilliant coloured fruits or berries as well which last well into the winter. In addition to this, nature has been a very thoughtful artist and has tinted the bark of a number of them so beautifully as in some cases to surpass their summer clothing. A good instance of this is the red-barked dogwood, or Cornus alba. A group of this in winter sunshine is every bit as fine as many flowers. It is especially fine when reflected into water. It is worth running over a list of many of these winter furnishers, as one may call them.

As far as autumn colour is concerned, there are a few outstanding plants which give us this in great perfection, always perhaps dependent on our fluctuating weather. Given a good growth in summer and a hot August and a dry fine spell in September and October, our colour is certain to mature. Few things are finer in our English landscape than the turning of the beech. Oak, elm and birch all contribute to this feast of gold. The first tree from which we get autumn effect is the rowan, or mountain ash. Unfortunately, the birds take toll of the glorious berries as soon as they are ripe. There are several fine forms of this tree, all of which are valuable.

It is hard to say which family of trees or shrubs produce the best effects of this kind. The Japanese maples are wonderful when they are in happy conditions. Scarlet oak, Quercus coccinea, the true form of this beautiful American oak, is an outstanding tree for autumn, as is also Quercus palustris. Two plants that seem to stand out there are Berberis Thunbergii, of which there are big groups planted in a sunny, rather dry position, which turned to a gorgeous reddish orange tint. Then, again, Euonymus alatus, which also has been planted in quantity in that beautiful wood, and whenever one comes into view of a group of this in October one has a fresh thrill of thankfulness for the colouring. It has an unique tint of rosy pink that is hard to describe and does not occur to my knowledge in any other plant.

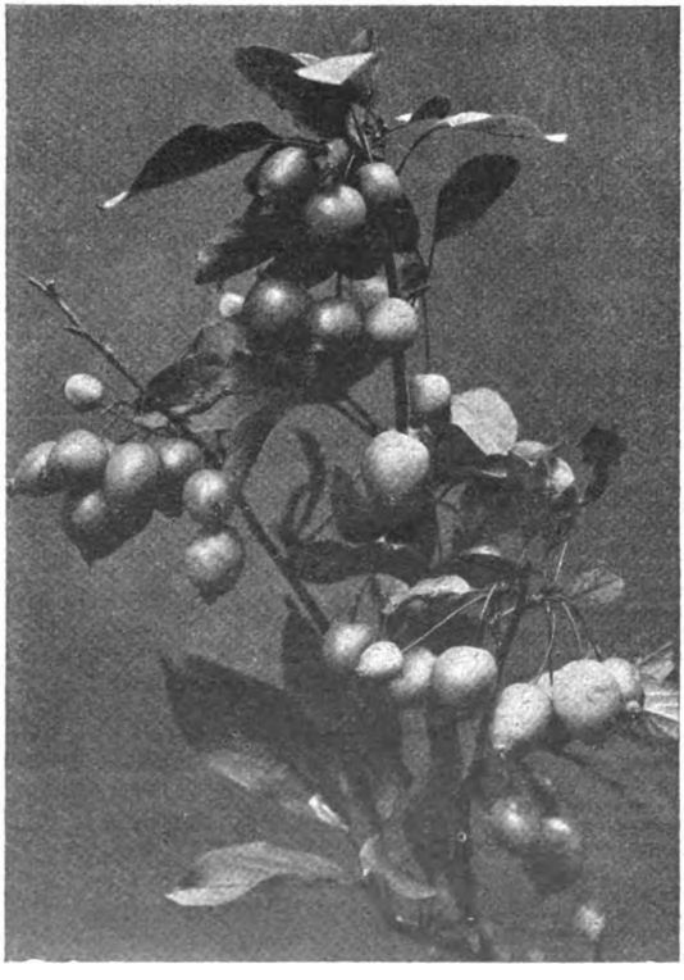
Euonymus yedoensis, the Chinese spindle tree, is also a fine autumn tint and winter plant, the fruit of this resembling our own native spindle tree, but of a beautiful shade of pink.

The common yellow azalea should be planted freely where autumn colour is wanted, and it holds its leaf a long time some years, which gives it an added value.

The crab apples must be held worthy of notice. Nothing is more brilliant than a John Downie in full and ripe fruit, and some of the others, such as Pyrus Malus atropurpureus, Pyrus Malus Aldenhamensis, etc., can be planted freely.

The Japanese cherries have their special value for autumn tint. But it is rather with the winter furnishers that we should turn to. Holly and yew are both beautiful, and not to be passed over are the yellow-fruited forms of both of them. These lighten up the winter sunshine most attractively. Callicarpa Giraldiana when fruiting well is one of the best shrubs. The fruit is small but the colour is very distinct—a bluish purple. Viburnum cassinoides has fruit of a similar tint. With them one can plant Vitis heterophylla.

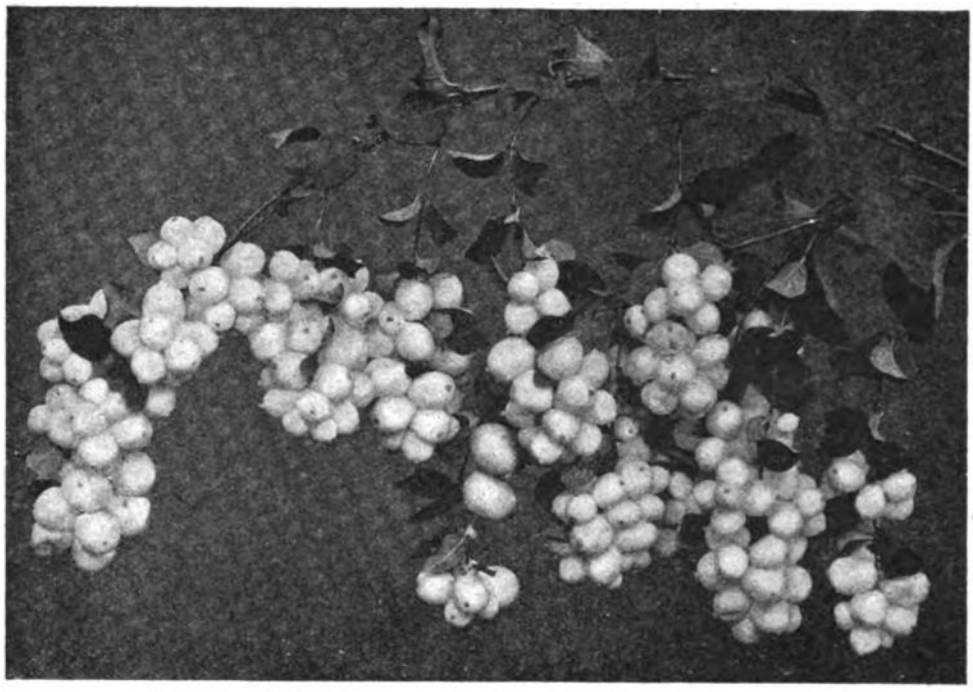
As a family the berberis are hard to beat. Autumn effect is almost certain to be had from such as B. Thunbergii, B. Coryii, B. brevipaniculata, B. stapfiana and others. They usually provide a fine effect from the turn of the leaf and are equally good in fruit, while B. setnensis and B. dictyophylla are particularly good in the colour of their ripened wood. One is always safe with berberis to get a good show in the dull months.



A GOOD AUTUMN COLOURER, PYRUS ELEYI, WITH PURPLISH RED FRUITS AND DARK RED FOLIAGE.

ONE OF THE BEST OF THE COTONEASTERS FOR AUTUMN COLOUR AND BERRY IS C. FRIGIDA.

Digitized by Google



THE DECORATIVE WHITE FRUITS OF THE SNOWBERRY.

Stranvæsias are outstanding winter effect plants. Although evergreen, the leaf takes on a lovely tint of colour, while their brilliant red berries, produced in great profusion, cannot be seen without pleasure. Another fine lot of plants are the cotoneasters, and C. frigida is one of the finest, although there are a number of others equally so in their way. C. horizontalis in full fruit is a lovely plant. A number of new cotoneasters have come in recent years from China, and the new fruited forms are certainly all worth planting for winter beauty. Snowberry is a charming plant with its white berries. One could, perhaps, make a catalogue of all these fruiting and autumn-tinted trees and shrubs, but my wish is more to call attention to the possibilities of their use. One cannot pass over the set of plants that give us their special beauty in the colour of their wood. The willows and red dogwood are very prominent examples.

Given a mild winter the rhododendron family are conspicuous. Our old friend nobleanum will produce flower for three or four months. It has a way of sending out a bud here and there, often, in the mildest winters, well before Christmas. One can see now and again a plant of this in full bloom with snow on their leaves, and nothing is more charming. Quite a number of the new Chinese rhododendrons may be termed winter flowering, such as moupinense, mucronulatum, lutescens, and, of course, a lot of the arboreum forms show flower long before the passing of winter.

Berberis Bealeii and japonica, Viburnum fragrans, corylopsis, winter sweet (chimonanthus) and hammamelis are wonderful winter-flowering plants and in woodland do not suffer from frost as in the open.

Jasminum nudiflorum is a plant of great charm, taking advantage of any mild day in mid-winter to push out a few blooms. The old Pyrus japonica is nearly always in flower on a south wall long before we discard our overcoats. Perhaps I have said enough on the subject, and will only say that many of the plants named are everyday things and generally well known, but, alas! not always planted.

F. GOMER WATERER.

CARNATIONS FOR THE GREENHOUSE

A Strictly Practical Article Giving Hints on How to Raise and Grow Perpetual-flowering Carnations Successfully.

THERE are few amateurs who would not love to grow at least a few of these popular plants in their greenhouses, but for difficulties which are suggested in the cultivation of them. These difficulties are really erroneous mistakes made by the cultivators in not fully comprehending the simple requirements of the plants. It is hoped that the following details will be of use in overcoming some of these difficulties. From December until March is the best time to take cuttings, and in taking a cutting the amateur must bear in mind that it will reproduce the parent plant in every detail, so that it is essential to take the most vigorous growths of the plant.

Taking Cuttings.

The best cuttings are found on the flowering shoots where a number of growths are generally produced, and from the point where these growths are thickest the best cuttings should be taken, where there is a short space between the leaves and while the cuttings themselves have scarcely any space between their leaves. The cuttings should be between 3ins. and 4ins. long and should be detached from the shoot with a slight downward pull, removing a small portion of the bark from the flower stem. This bark should be trimmed with a sharp knife, as a clean cut calluses more easily than a ragged surface and roots are emitted in a shorter time. If the shoot comes away without any of the bark it is too soft and will not root.

"Pipings" are taken of varieties that do not produce cuttings until after the flowers have been cut. They are simply young growths pulled out at a joint, but the wood of the growths must be in the proper condition from which they are being taken from is exactly halved in the breaking. The correct to allow the break to occur so that the joint

A CARNATION SHOWING WHERE TO TAKE THE CUTTINGS.

wood for propagating is that which is in a half-matured state.

Occasionally "layering" is practised with varieties whose cuttings are difficult to strike, but this is only resorted to on such occasions and the process need not be detailed in this article.

Rooting Medium.

The best rooting medium for the cuttings is pure sand, and they may be either dibbled into boxes or pots according to the numbers required. Which ever is used, they must be well drained with potsherds or ashes and the sand pressed down firmly in the boxes to half an inch from the top of the boxes. The cuttings are inserted 2ins. apart.

Bottom heat was always advocated by old growers of carnations for the rooting of carnation cuttings, but results obtained from rooting them in a house with a temperature of 50 to 55 degrees are quite as satisfactory if not more so, as the cuttings have not been unduly excited and stronger and sturdier plants are obtained. Twenty-eight days is the average time for the rooting of cuttings.

Watering and Ventilation when Propagating.

It is impossible to give exact details of cultivation, as one cannot work by rule of thumb, but must be guided by circumstances. On bright days, the cuttings must be shaded, but not repeatedly sprayed overhead, as many amateurs do. The whole secret of carnation propagation lies in keeping the cuttings fresh without excess of moisture on the foliage. During the first few days after the cuttings are put into the boxes, they are like cut flowers and can only take up water to keep them fresh, so that there should be no lack of it in the sand. This will prevent the base of the cuttings becoming dry while forming

Digitized by Google

a callus. After this has formed the cuttings do not take harm so readily from dryness.

Light, heat, moisture and air must be controlled by artificial means, but to go to the extreme in any of these matters is as bad as ignoring them. If the cuttings receive a thorough watering in after they are dibbled into the boxes, it will be found that little watering or sprinkling overhead will be required for the three or four weeks it takes to root them. Should the sand dry out before then, do not hesitate to water.

Potting Rooted Cuttings.

As soon as the cuttings have rooted they must not be allowed to remain in the sand, but should be potted on into 3in. pots, potting the plants which show strong rootlets. Be careful when lifting the plants out of the boxes not to injure the young rootlets. Put one good crock over the bottom of the pot, then a little compost, which should consist of five-sixths stiff yellow loam and one-sixth sand, but the latter should be used in accordance with the quality of the loam, *i.e.*, heavier loam requires more sand. Dip the roots of the plant to be potted in tepid water, so as to wash off the sand, as a ball of sand is apt to become dry much more quickly than the surrounding soil, thus injuring the plants. Allow the roots of the plant to rest on the soil in the bottom of the pot, spreading the roots out well. Fill up with the compost to within half an inch of the rim of the pot and make the compost moderately firm. The ideal position for the plants is one receiving full sun and an abundance of air, with a night temperature of 45 degrees. Always strive to obtain a sturdy well matured plant.

Treatment of Young Plants.

After the rooted cutting is potted it should receive sufficient water to penetrate to the bottom of the pot; after that it should only be watered when the soil shows signs of getting dry. On very bright, drying days damp the house down and spray the young plants overhead, but never carry the latter to excess, as it encourages a soft growth, which is not natural to the plants. Shade the plants if necessary from strong sun, keeping a temperature of 50 degrees during the day, always allowing as much air as possible.

This treatment encourages a slow, steady growth and keeps in check insect pests which would doubtlessly attack weakly grown plants. A sturdy grown plant with practically no spaces between the leaves can only be obtained by cool, light and airy conditions.

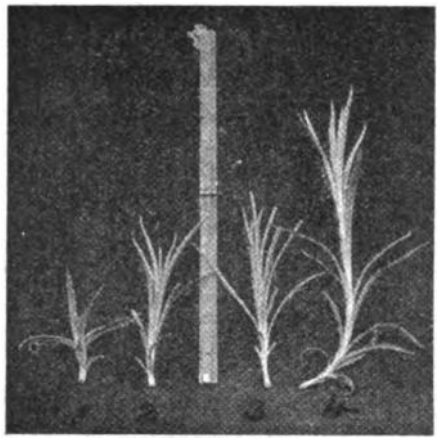
Stopping Young Carnations.

When the 3in. pots have become full of roots, it will then be time to pot on into 5in. pots. But before this second potting takes place the young growths will require to be pinched or stopped. This is done to encourage young growths and so form a bushy plant, which will, in turn, produce a quantity of flowers. If the plant is not stopped it will produce a single small flower stem and break naturally into growths, making a long, straggly plant. Stopping should be done in the mornings when the growths are stiff and brittle, and it is done by simply removing the entire top of the plant at the sixth joint, so that the remaining eyes are in an equal state of maturity and break away evenly, thus obtaining an evenly balanced plant. If the plants are potbound, weak growths will be obtained, so it is necessary to stop when the plant is maintained by free root action.

The compost for the second and third pottings is four-sixths loam, one-sixth manure, one-twelfth wood ashes, one twelfth mortar rubble and a little sand, according to the texture of the loam.

Potting on Young Plants.

The second and third pottings are performed in the same manner as the first potting. The firming of the soil should be done with a rammer. In the case of a light, sandy soil it is difficult to get it too firm, while heavy soil is quickly spoilt by over firming. Crocking of the pots must be done particularly well and no dirty pots should be used.



TYPES OF CARNATION CUTTINGS.
Good and bad: the one on the extreme left is too small, while the one on the right is too large.

A second stopping ot the plants will take place when they have been potted the second time and have matured a number of well matured growths. This is done gradually, one growth per plant at a time so as not to check the plant unnecessarily. Stop again at the sixth joint, removing the top growth of the shoot and the second stopping must cease according to the time blooms are required, remembering that the stopped growth will not produce flowers until about five months later.

Staking.

Plants require to be supported, and the best results are obtained by placing a bamboo cane in the centre of the pot and supporting the growths by wire rings, which can be bought for the purpose and which are fastened to the cane.

Disbudding of the flowering shoots is necessary. All lateral buds close to the crown bud should be removed when they are large enough to handle.

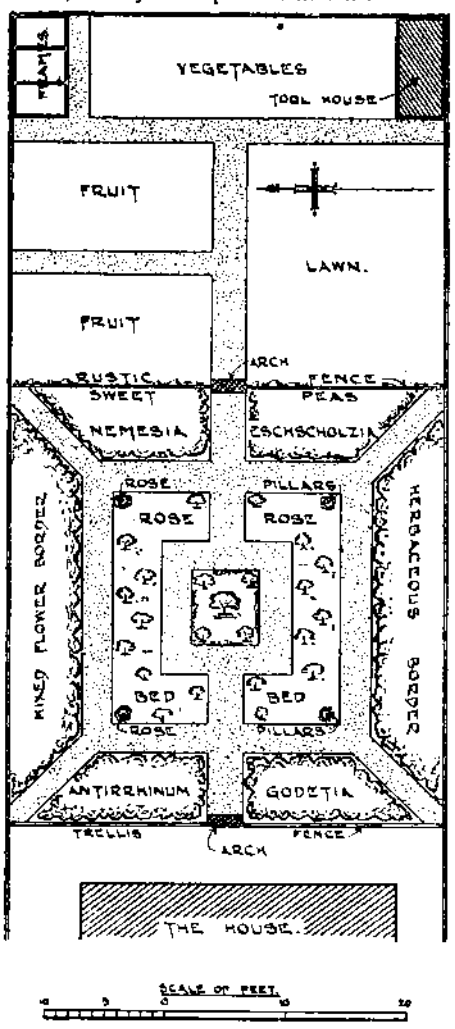
Feeding.

After the plants have received their final potting and when the plant has filled the pots with roots, feed during the summer months every fortnight and during the winter months only once a month. This gives an extra stimulus to the plant. M. H. G.

A GARDEN DESIGN

This design represents a flower, fruit and vegetable garden that may be increased or reduced in size to suit individual requirements. The object is to provide a suitable lay-out that may be formed and maintained at a moderate expenditure of money and labour.

WHILE the planting of the beds will, of course, be arranged according to the personal taste and ideas of the owner, it may be explained that the scheme



lends itself to the formation of a miniature rose garden in the centre. It possesses great possibilities in the direction of colour effect, and the hybrid tea varieties maintain a maximum period of bloom from early summer until late autumn Assuming, for instance, that the small bed in the centre is planted with Etoile de Hollande (crimson), a weeping standard of Emily Gray (yellow) would make a pretty combination, and four pillar or standards of Frau Karl Druschki in each corner of the square would blend with Shot Silk, Mrs. Henry Bowles, Betty Uprichard and Los Angeles, four pink shades to occupy the end positions with Mabel Morse (yellow) and Angele Pernet (orange yellow) at each side.

The trellis fence next the house should be clothed with rambler roses chosen from Excelsa, Emily Gray, Dorothy Perkins, Hiawatha and other Wichuraiana specimens; and Yvonne and Desire Bergera might be suggested for the two arches. Both the herbaceous and the mixed flower borders will meet with approval, but the four beds of annuals may be discarded in favour of begonias, carnations or other flowers. The row of sweet peas forms an ornamental background to the flower beds and also supplements the supply of cut bloom for house decoration.

It is an advantage in many ways to devote a particular section of the garden to fruit culture instead of scattering the trees and bushes all over the garden, as is frequently done. The taller apple, pear and plum bush trees may be associated in one bed with the dwarfer forms of gooseberries, while the other bed is available for currants, raspberries or strawberries, and the walls facing south may also be put to a similar purpose.

The vegetable space is intended principally to keep the house supplied with salads, and the frames and tool house are indispensable.

The question of edgings depends to a large extent on personal taste and the state of the finances. Wood is not economical; box looks well when kept in good condition; but if stone is available and not too costly, it is the most suitable of all edgings for a flower garden.

ROSES WHICH MAKE GOOD HEDGES

IN the selection of roses that are suitable for making hedges the grower has to consider the type of hedge that is required, and care must be exercised in selecting sorts that are suitable for the particular purpose. One often notices, for example, that the Penzance briars are recommended for forming a hedge. They are, without doubt, splendid subjects for hedge work, but they require ample room for development if their beauty is to be seen at their best, and this demands a position where there is plenty of room. With one or two exceptions the Penzance briars are most rampant growers, and if the position in which they are growing is a confined one the long growths must be kept in bounds by very severe cutting, and when that is done, most of the flowering shoots are removed. The result is that—owing to this constant cutting—the plants grow stronger than ever, and they soon become a perfect nuisance. A hedge formed of some of the Penzance briars should, therefore, be planted only in gardens where plenty of space is at command. Hedges formed by planting the Penzance briars are exceedingly pretty when in bloom, and they have an equally attractive appearance in autumn when the plants are loaded with brilliantly coloured fruits.

The most vigorous grower of the lot is Anne of Gierstein. The colour is a dark crimson, and the foliage is very sweetly scented. Meg Merrilees is somewhat similar in colour and is also a strong grower. The colour of this variety may be described as a rosy crimson. Jeannie Deans, a semi-double crimson, also comes into the strong growing category. The three sorts mentioned are all more or less of a crimson colour and are suitable for planting in association if a hedge of about the same character of growth and of a red tone of colour is required. When we come to pink shades of colour, we have Rose Bradwardine, a pale rose; Amy Robsart, a rich bright rose; Julie Mannering, a pale pink; and Lucy Bertram, a deep rose. These are all strong growers.

Varieties of the Penzance group that are not just such rampant growers as those already mentioned are Lucy Ashton, white with a pink edge to the flower; Brenda, a peach coloured variety; Flora MacIvor, almost white except for a pale flush of rose; Edith Bellenden, pale rose; and Green Mantle, pink with a white ring in the centre of the flower. In Lord and Lady Penzance we have two very beautiful sorts, but they are not—in most places—so strong in growth as the sorts already named. Lord Penzance has fawn and light yellow flowers, and those of Lady Penzance are soft copper with a suffusion of rose. They are both very beautiful things, but it would be out of place to associate them in a hedge with the others. They would be overgrown. Their somewhat weaker constitution is caused by their having been bred from Austrian Yellow in one case and Austrian Copper in the other. These two kinds, nevertheless, make a very pretty hedge or screen, but, as already noted, they must be planted by themselves if a hedge of about similar height in growth is required. In order to get the best effect from a hedge of the strong Penzance sorts I always advise that they be planted 5ft. apart, and pruned hard back in March. This prevents undue overcrowding and gives a more graceful effect to the hedge once it has become established.

The common sweet briar makes a good hedge, but it does not grow so strongly as the Penzance sorts. The double scarlet and the double white sweet briar are also good for a hedge, but these seem to have disappeared from commerce. Janet's Pride, a sweet briar with semi-double white and rose flowers, is still offered. These sweet briars should be planted 4ft. apart.

Visitors to the Border districts of Scotland are often impressed with a yellow rose hedge they note when motoring north, and there are constant enquiries as to what variety is used for this hedge. I have seen a number of those hedges in different parts, and I have noted three kinds of yellow roses that are used. The most beautiful, to my mind, is Harrisonii. This is a double golden yellow, and it is, when established, a most profuse flowerer and is also a good grower. It will form a hedge 6ft. or more in height. Persian Yellow is another that is used. It makes a nice attractive hedge, but I hesitate to advise its use in the rose garden owing to its proneness to black spot. The other is the old double yellow Scotch rose. It is not so strong in growth as the other two, but it makes a good low hedge. It should be noted that all the roses mentioned only flower once in the season.

For low hedges about 3ft. to 4ft. in height the old Scotch roses are quite good, and the only objection to them is that they flower for so short a season. They have practically disappeared from catalogues, and I really think there need be little regret for them. I am of the opinion that if we want to make low hedges of roses, some of the new breaks in the polyantha section are ideal for the purpose, and they actually give us flowers all through the season. One of the very best in this respect is Else Poulsen. It will grow 3ft. or more in height, and it is always in bloom. The semi-double flowers are bright rose in colour. Leonie Lamesch, a polyantha with coppery red flowers, is another sort that makes a good hedge.

Some of the China roses are good growers and are often used in gardens for low hedges, and they flower almost perpetually. The common blush is one of the best, and Fellenberg, deep rosy red, may be coupled with it. Gloire de Rosomanes is a vigorous grower and is good for a hedge about 4ft. or 5ft. in height. This is a very old rose with brilliant crimson flowers, borne in bunches.

A WELL TRAINED SCREEN HEDGE OF PENZANCE BRIARS, WHERE GROWTH HAS NOT BEEN ALLOWED TO BECOME RAMPANT.

Coming now to sorts that flower over a longer period and all of which are suitable for hedges, I think Zephirin Drouhin is one of the loveliest and sweetest of all for the purpose. If well treated and pruned hard back the first season after planting it will soon make a hedge 6ft. in height. It flowers very freely and is at its best in autumn, owing, no doubt, to the large infusion of Bourbon blood in its parentage. The colour is a rosy cerise. This rose is a great favourite and worthily so. It is difficult to know why some of the other old Bourbons of similar sweetness and beauty have fallen from grace. The old Bourbon Queen, with its deep rose, fairly large fragrant flowers, is an ideal rose for hedges. So, too, is the old Mme. Isaac Perèire. Its colour is a vivid carmine, and although the flowers are large and lumpy, they are deliciously fragrant. It is an old world flower, with a grace and attraction of its own, and few, very few, of the more modern sorts can equal it either as a pillar rose or as a rose for the formation of a hedge.

Madalena Scalarandis, a little known China, is a vigorous sort with pale rosy pink flowers, and it makes an attractive and almost perpetually floriferous hedge. It is still in commerce.

The selection given in this article will enable growers to choose sorts for hedges of varying stature. If a very tall hedge is wanted it can be obtained by selecting the stronger growers in the Penzance section. For a hedge not quite so tall the more medium kinds in that section may be chosen. Then we have the Bourbons, followed by the Chinas and polyanthas. The ground upon which the hedge is to be planted should be well manured before putting the plants in, and, with the exception of the polyanthas, all should be pruned hard back the first season after planting in order to get them into vigorous growth and then to be well established.

The next note will deal with roses that form large bushes and are, consequently, valuable for positions where they can stand isolated so that their full beauty as flowering shrubs may be revealed. GEO. M. TAYLOR.

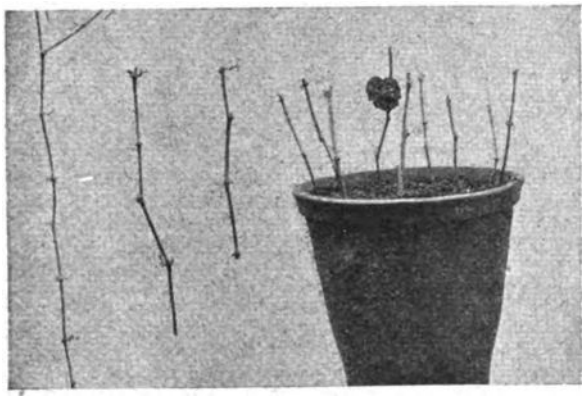
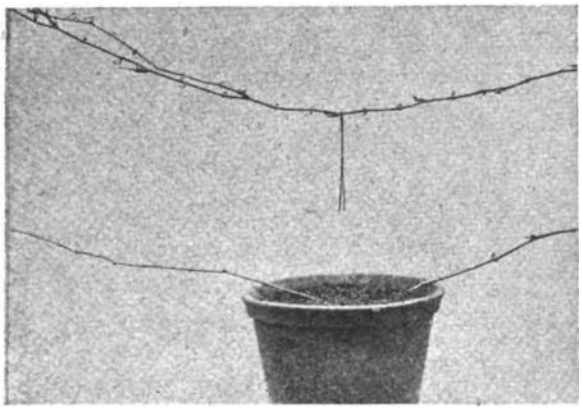
THE BUSY MAN'S PAGE

Propagating Virginian Creeper.

AMPELOPSIS VEITCHII, as well as the older ampelopsis or Virginian creeper, familiar to most readers from their childhood, may be propagated by cuttings and layering the shoots. A. Veitchii strikes very readily from cuttings and yet few amateurs raise plants in this way for themselves. Prepare cuttings some 6ins. in length, selecting fairly ripe shoots of the current year's growth for the purpose. The right kinds of growths to select can be seen in the illustration, and each growth should be trimmed off immediately below a joint. Insert the cuttings in a 5in. pot that has been well drained and filled with a compost of sifted loam, leaf-mould and coarse silver sand in equal proportions. The



CUTTINGS BEFORE AND AFTER INSERTION.
Note that the cuttings are placed round the edge of the pot.



THE METHOD OF LAYERING A GROWTH OF THE CURRENT YEAR IN A POT.

cuttings should be inserted 2ins. deep round the edge of the pot and the soil at the base of each cutting should be made quite firm. The pots should then be watered and stood in a cold frame or cool greenhouse. It is wise to leave the rooted cuttings in the pots in which they have rooted until the succeeding autumn, and then to plant them out.

Layering of ampelopsis is also a simple means of propagation. This operation may be done in the open ground or in pots. In the open ground where suitable growths are obtainable, all that need be done is to form a shallow basin-like cavity in which should be placed a small quantity of sandy soil. The layer should be bent down and a cut made nearly half through the stem just below a joint, a peg being fixed across below where the cut is made. Soil should be added in sufficient quantity to cover the cut and the stem round about it. Much the same method is adopted when the shoot is layered in a pot, as seen in the illustration.

Waterlogged Soils.

BADLY drained soil quickly becomes sour and acid through the exclusion of air from the minute spaces between the soil-particles. It is useless expecting good crops from ground in this condition, and no matter what pains are taken in other ways to promote fertility, disappointment is sure to follow. Deep digging in autumn, leaving the surface rough in winter, facilitates drainage and is beneficial in any case; but when water does not pass freely through the soil at all times something more is needed, and recourse should be had to pipe drains, or to some such means of disposing of superfluous water. For permanent results, pipes should be given preference as, although the cost may at first seem heavy, in the end it will be found the most economical method having regard to its efficiency and long-lasting character. In stiff clay the drains need not be deeper than 2½ft., and 12ft. apart will be a suitable distance. Another way is to dig trenches 3ft. deep and place in the bottom to the depth of 9–12ins. coarse materials such as stones, broken bricks, clinkers or whatever will allow water to pass through freely, afterwards filling in with soil. When neither of these methods is employed, a deep ditch in the lowest part of the garden will be of some service in promoting drainage. If fruit trees are to be planted, or are already occupying the ground, see that the drains are midway between the rows. Subsidiary drains can be made to connect with the former if desired, to form the well known herring-bone system. The main drains should be constructed with 4in. pipes; the lateral ones will not require pipes of greater diameter than 2ins.

Work to be Done Now in the Greenhouse.

GLADIOLI as pot plants are still unknown to many amateurs, but when they are once tried as such they are considered as worthy of a place in the greenhouse or living-room, as do tulips or hyacinths.

Plant five corms 1in. deep in a 5in. pot in a compost of two parts loam and half a pot each of well decayed manure and silver sand. Crock the pots well and over the crocks put a few pieces of fibre from the loam to aid drainage. After potting water the bulbs and stand them outside on a cinder or ash path and cover with bracken or cinders until growth begins.

The early flowering varieties should be used for this purpose, and there are a number of beautiful varieties. The Bride, which is pure white, is very pretty; Brilliant, a vivid scarlet; Peach Blossom, rosy blush blotched with rose and cream; and Blushing Bride, a white with deep crimson markings—all are good.

Roman hyacinths potted in August and put under ashes can now be lifted and placed for a few days in a cool, semi-dark place to insure them to the light, afterwards they can be brought into a temperature of 55 degrees.

Watering of plants in greenhouses should be done very carefully from now on until March. Geraniums and phyllocactuses scarcely require any water; keep the soil nearly dry. Watering is best done in the forenoon and no plant should be watered unless the soil looks dry.

Primulas.—Plants required to bloom by Christmas should be encouraged by manure and soot water alternately, provided the pots are well filled with roots. Do not attempt to force the plants by placing them in warmth, as they never succeed if thus treated. Primula obconica grandiflora, P. kewensis and P. malacoides will flower throughout the winter if the faded flowers are removed regularly.

Planting Roses.

THIS is the most suitable period of the whole year for planting roses, provided the ground has already been thoroughly prepared. Owing to this recent spell of dry weather the ground should be in a suitable condition and no time should be lost in getting on with this work. Be careful to make the holes large enough to accommodate the roots when the latter are spread out. As regards depth, be guided by the mark of the soil on the stems, which will indicate the depth at which the plants were growing in the nursery, and plant them slightly deeper. All damaged roots should be cut off cleanly and the soil trodden firmly. Standard roses ought to be staked and tied before the holes are filled in, thus preventing any damage to the roots. When preparing new rose beds it is essential to see that no fresh manure is added. All manure that is used should be thoroughly well decayed, and should be incorporated with the lower spit, and it is most important that manure is kept from actual contact with the roots.

Covering a Corrugated Iron Shed.

ALTHOUGH the corrugated iron structure is often extremely useful, no one can pretend that it improves the appearance of the garden. To cover a shed of this nature with creepers is not quite such an easy matter as when dealing with wooden erections, but with a little care much may be done to hide the unsightliness of the hard metal outlines. A very good plan is to drive strong nails about a foot apart at each corner of the building. Between these lengths of strong wire should be stretched, and in this way support will be secured for some of the strong-growing climbing plants. Non-clinging climbers should be selected, such as hop, cobæa, virginian creeper, Polygonum baldschuanicum and polyantha roses. These plants will soon screen the shed, at any rate in the summer, and even in the winter will do much to hide the more ugly features of the structure. By means of special treatment it is even possible to prepare an iron fence or shed so that clinging plants like ivy and the Ampelopsis Veitchii can secure a hold. For the purpose prepare a special mixture to apply to the iron. Get four handfuls of cement and two handfuls of lime and mix them with water until rather a stiff batter is secured. The mixture should be applied to the iron with an old brush. It is a good plan to give two or three coats, allowing a suitable interval for drying between each. The preparation is best applied in the autumn as soon as the climbers are planted, for they will cling all the better to the surface if it has been exposed to the weather for a while. It will be found that almost any of the climbing plants that cling will do well on a prepared surface of this nature

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Grow More Trees.

IT is well known that leaves, in carrying out the processes of food-making, return free oxygen to the air, and in this way are very valuable purifying agents. In towns, where we use up the oxygen very rapidly, the growing plants assume great importance, every additional plant meaning a slightly improved atmosphere. Trees with their huge heads smothered with leaves are probably more beneficial in this way than any other class of plants, and for this reason alone their planting in town gardens and streets should be encouraged. In the garden I would encourage tree planting for the additional reason that trees break the skyline, hide ugly buildings (of which there are only too many), and give a beauty and distinction to the garden which cannot be obtained by any other class of plants.

But, of course, this does not mean that any and every kind of tree can be bought and planted without consideration. A tree once planted remains where it is during the whole of its lifetime. It cannot, as a patch of bulbs might, be moved from year to year into a fresh situation. Moreover, a tree which during the first three or four years may be suitable for a small garden would perhaps after that time grow too large to be accommodated without severe pruning, and pruning is to be avoided where possible. For a small garden, therefore, a tree of small habit, not too spreading, is best. Trees that give flowers and berries as well as foliage are to be recommended, such as the mountain ash and white beam (Pyrus aucuparia and P. aria). Trees whose autumn tints rival the colours of the border flowers are also good subjects for the small garden. Ailanthus glandulosa, the tree of heaven, which is just now shedding its glorious red leaves, is a favourite town tree, but it must be confessed that in a small garden this tree will outgrow its allotted space unless it is prevented. It grows well, however, if it is cut back to the ground each spring. The new shoots should be limited to one which will produce fine leaves several feet long. The Norway maple (Acer platanoides) is another tree which will grow well in the town garden and produce foliage of great beauty.

Planting.

If a tree does not succeed after you have planted it, do not blame the nurseryman unless you are sure the fault is not yours. As already mentioned, trees have to remain their whole lifetime in the same site, and they therefore deserve some care in its preparation. It is not necessary to put manure at a great depth, but it is necessary to break up the subsoil and to see that it is well drained. Otherwise the roots may become waterlogged. A little organic manure should be worked into the top soil, but this should be well mixed, and the manure should not come into actual contact with the roots at the time of planting. A hole to receive a tree must be *wide*. The roots can then be well spread out in a horizontal position. A very common mistake is to allow the roots to drop vertically into a narrow and deep hole. The result is that these roots are huddled together and are not able to reach the food supplies which are most plentiful in the top 12ins. of soil.

November is the best planting month for most trees, and those who can spare room for a few ornamental trees should order them immediately and plant them at the first favourable opportunity. Do not be misled into the idea that you will be merely planting for posterity—ornamental trees are charming from the first season, and will amply repay you by their increasing beauty as the years go by.

A Selection of Dwarf-growing Trees.

Amygdalus communis (almond), Ailanthus glandulosa (tree of heaven), Acer platanoides var. Reitenbachii (purple-leaved Norway maple), Betula alba (silver birch), Crataegus oxyacantha (double scarlet thorn), Prunus padus (bird cherry), Cercis Siliquastrum (Judas tree), Ginkgo biloba (maidenhair tree), Liquidamber styraciflua, Laburnum vulgare ("Golden Rain"), Populus (balsam-scented poplar), P. Bolleana (Bolls poplar), Prunus persica (double red peach), P. Pissardii (purple-leaved plum) and Pyrus floribunda (crab).

Points About Manuring.

FARMYARD manure is the most valuable of all natural manures, but the greater part of its value lies in the fact that it returns so much humus to the soil.

Artificial fertilisers are quite suitable, and as good as farmyard manure *if humus can be given* to the soil at the same time.

A compost pit into which all vegetable peelings and other household refuse, together with weeds, leaves, etc., from the garden are put from time to time will provide sufficient humus for an average small town garden. Of course, such a pit should be screened from view, and its contents covered with a layer of soil and lime occasionally to keep it from becoming a nuisance.

Spent hops, leaves and green manure (*i.e.*, mustard or other seed sown in autumn and dug in in springtime) can all be used to add humus to the soil.

Animal manure should never be kept exposed to the weather. *In the soil* is the proper place for manure to decay. Manure stacked in heaps loses the greater part of its nitrogen by the wastage of ammonia which drains away.

Only slow-acting manures and fertilisers should be used at this season. Bone meal, basic slag, farmyard manure and fish manure are suitable for application during autumn digging.

Evergreen Shelter Hedges.

HEDGES within a garden are required for ornament, shelter and as a dividing screen. The most important of these, I think, is shelter. It is a pleasure to us on a windy day to walk within the shelter of a yew hedge that changes the whole feeling of a garden. And how the plants must appreciate it! Yew is too poisonous to live stock to be grown as a hedge plant on boundaries, but inside the garden it can be used with safety. Nor is it so slow growing as is usually imagined, provided the site is trenched properly and is well manured. Small seedling are best. All they need is to be kept clean and given a friendly top-dressing of nitrate of soda during the growing season. Berberis stenophylla is another good hedge plant, and can be used on boundaries. It is a close grower, very prickly, and would prevent even pussy from breaking through if pruned back occasionally to induce a thicket of basal growth. It can be clipped or cut back after flowering to restrict it to hedge proportions. The use of secateurs is best. They leave the small shoots, and it is possible to cut back a berberis fence and leave it with the appearance of never having been pruned at all. That is the art of pruning, to conceal the wound. Of course, where there is plenty of room, berberis can be allowed full fling, and rich will be its fountain of flowers.

Another plant that will make a shelter hedge where there is plenty of room is Laurustinus (Viburnum tinus). It is evergreen, and seems to flower all winter—truly a gem. Cut it back into shape like berberis from time to time. Holly is another shelter fence plant that is evergreen. Again, small plants get away quickest if properly tended. Cupressus macrocarpa is another that makes an excellent screen for a suburban garden.

NOTES ON THE FLOWER GARDEN

The Value of Pinks as Edging Plants.

ALTHOUGH regarded as one of the most humble and lowly of our garden flowers, there is no doubt that pinks are among the most useful and decorative plants, and they deserve better recognition in this respect Few plants can equal them for dry, sunny situations, and they are equally at home in damper spots; but, like most plants, they appreciate something between the two extremes. And, while not becoming decadent in a poor soil, they, nevertheless, appreciate the richness of good soils.

I think one of the most charming places for pinks is the kitchen garden, as an edging. Here they take away the sombreness of the ground when it is bare, in winter and spring, and form a beautiful frame for the various greens of the vegetable plants in summer and autumn. In fact, pinks can help to form an actual colour scheme in the kitchen garden, and make that department as attractive as the flower-bed and border may be.

A DECORATIVE EDGING OF PINKS IN THE KITCHEN GARDEN.
An admirable idea to make this part of the garden beautiful.

The accompanying illustration will show what a wide bed of pinks can do for a large kitchen garden of the old type, with its box edging. There is one thing about the box—it does keep the path tidy, and when flowers are grown as an edging it keeps them off the path too, and helps them to maintain their erectness, thus showing off the beauty of the flowers to advantage. What is done in the large garden can be equally well carried out in a small area, for the pink edging is possible everywhere. A row of plants by the side of the main paths will be sufficient in the small garden.

There is no difficulty whatever concerning the growing of pinks. Left to themselves they increase each year, and may be thus treated if masses of flowers are wanted; but in most cases it will be found desirable to lift the plants every three years or so, divide them up into smaller ones, or cuttings may be struck and a fresh lot of plants be raised, say, every two years. Huge masses of any plant encourage insects, although pinks are not such good hiding-places as many other low-growing plants are.

If you want pinks to give their best, let them have a medium soil of good quality—that which is found in the vegetable garden as an example. Sandy loam is good, and they will not do so badly in almost pure sand. In stiff soils and very damp soils, especially in low positions, pinks often fail to flower satisfactorily. The plants love sunshine and exposure; they will stand drought as few other plants can, giving an abundance of flowers at the same time.

A good form of edging that is useful for a raised garden bed is that composed of alternate rocks of clinker or other stone with a clump of pinks, perhaps of varying colours. This makes a permanent edging far superior to plain boards, tiles or other material, and certainly more decorative. The grey of the foliage, filling the space between the dark rocks, shows up against them to great advantage and, when covered with blossoms, makes a pretty sight.

Everyone knows, of course, that pinks form an excellent edging to flower borders and certain styles of beds. The plants can be grown in conjunction with bulbs, too, for it is easy to plant crocuses, bluebells, grape hyacinths, etc., among the pinks. The bulbs will push up above the grey foliage and form a beautiful floral edging in the early spring before the pinks begin to bloom, and the bulb flowers and foliage will have disappeared before the pink blossoms come. Autumn crocuses could follow, and thus a succession of blossom kept up in the edging. And all the dreary winter, when no flowers grow, there remains the beauty of the grey and silver foliage to make up for lack of floral effect. Surely a better plant for an edging could not be found than the pink.—B. S. S.

A Hedge Hint.

IN course of time many hedges become somewhat bare at the base and there may be considerable gaps at intervals. A very good way of dealing with a hedge of this description was shown to the writer recently. The base of the hedge was filled out by building a rough bank of some pieces of turf that had been cut from a piece of waste land. The turf employed was of very coarse grass, and it would not have been of the slightest value for the making of a lawn. The formation of the bank was carried out in this way: The turf was piled, grass side downwards, one above the other to the height of about a couple of feet, which was more than sufficient to close all the openings. The width of the turf bank was about 15ins. The turves were beaten down well with a spade in order to consolidate matters as much as possible. On the top of the bank a layer of good soil was placed in order that the bareness of the stacked turf might be relieved with flowering plants. Shade-loving subjects were found to be the most suitable, and ferns, violas, primroses and violets found a situation to their liking. Such a bank would be an admirable position for daffodils, which would give a charming effect in the spring. The grass soon grew out to the front of the bank, and by cutting this bank a neat green surface was maintained. The layer of soil at the top being quite 8ins. deep, there was little trouble with the grass working up from the turf. The arranging of a bank of this nature would be likely to make the growth of the hedge plants more vigorous and improve them in all ways.—L. B.

Marsh Marigolds for the Margin of a Pool.

MANY will be well acquainted with the marsh marigold or kingcup (Caltha palustris) of the bogs and marshes of the countryside; but perhaps not so many have enjoyed its beauty in close proximity to the garden. For some years we have had it in a bog near the edge of a lily pond, where its large golden-coloured flowers are a great source of pleasure in the spring. Both the type and the double-flowered forms are grown, but the variety known as Tyermanni should be obtained, if possible. This, perhaps, is the finest of the kingcups, producing eighteen or twenty beautiful yellow flowers on a single spray, and, moreover, they are well above the foliage.

The Pontic kingcup, C. polypetala, is also a delightful subject for shallow water or near the margins of streams or ponds. It is a vigorous plant, with leaves a foot across, and strong spikes of golden flowers which are 3ins. across and larger than in C. palustris. It is a native of the Alps of Armenia, North Persia, etc., and when shown before the Royal Horticultural Society on April 17th, 1906, it received an award of merit which it richly deserved. It is surprising that such a glorious plant was not introduced some years earlier; but now it is quite common, and can be secured at a reasonable price. There is a legend concerning this marsh marigold, and hence the name Pontic kingcup. It was stated that this plant only grew in the ponds of the Vatican, and the Pope refused to furnish outsiders with any roots; but one day a plant-lover succeeded in hoodwinking the custodians, and eventually fished out a few pieces of this wonderful caltha with his umbrella; moreover, he got away safely with his treasure.

Although the ideal situation is by the lake side and in swamps for all the calthas, especially C. palustris, they may be grown in the border, particularly those of a damp nature. Much can be done with tanks, tubs and small concrete pools, while bogs connected with the rock garden might well contain a colony of C. polypetala and C. Tyermanni, if not the native C. palustris. Here they will succeed in a peaty soil and flower freely every spring, remaining in full beauty for several weeks. I have seen them employed as cut flowers, with very pleasing effect.—B.

A Selection of Useful Rock Roses.

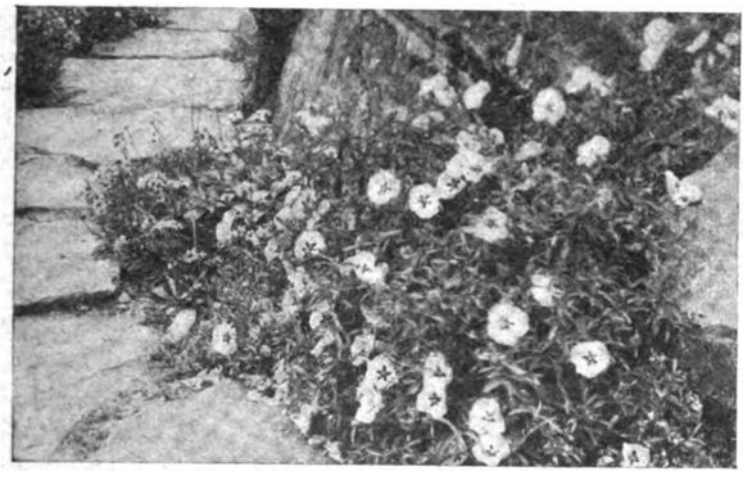
IT is a matter for regret that the rock roses are not more widely grown, seeing that they will thrive where many plants would barely exist. True they blossom during the morning and are more or less closed in the afternoon, but even so, they are most floriferous and create a brilliant display for several weeks. Many of them are more hardy than is generally supposed, and where they are not likely to resist a severe winter, it is an easy matter to insert a potful of cuttings in July or August, and keep them in a cold frame or cool greenhouse during the winter months. All are readily increased from cuttings.

The rock roses or cistus transplant badly, so it is advisable to transfer them to their flowering quarters when quite small, and to trust to pot-grown specimens. The cistus are essentially sun lovers, so positions fully exposed to the sun's rays should be chosen, and remember that better results are obtained from poor, stony soil, than from a rooting medium of average quality. In the former the growth is less rampant, it is short and firm, free flowering and is more likely to resist frosts than a lot of sappy growth produced from a rich soil. Many of the cistus could occupy a site on the rock garden, dry banks will be found suitable, while beds in the pleasure grounds or near the dwelling house would be a noteworthy feature.

Individual flowers are short lived, but this is not detrimental, because others take their place and the supply of fresh blossoms are kept going for quite a long period. The rock roses are fairly quick growers, but with a few exceptions they do not exceed 3ft. in height, and rarely need any pruning. A little trim over after flowering is all that is required. There are quite a number of these charming plants, and one of the best is C. purpureus, with rich reddish purple flowers 3ins. to 4ins. across, the dark red blotch at the base of each petal is an additional charm. C. crispus is rather dwarf in habit, with rose coloured blooms, while Sunset is somewhat similar, with flowers of a bright rose shade. Then we have C. laurifolius, with white blossoms, and this plant will form a shapely bush 6ft. to 8ft. high, and the white C. florentinus is remarkably floriferous, while the habit is rather spreading. C. Gauntlettii is also an acquisition, and no collection would be complete without C. Loreti, the base of each large white petal being stained with a crimson blotch.

Another charming and well-nigh indispensable rock rose is C. Silver Pink; in fact, there are now several exquisite pink forms, which are decided acquisitions to a genus already well blest with delightful species and hybrids. Quite distinct are the somewhat straggling C. algarvense and C. formosum, but on account of their yellow flowers, they deserve to be grown, especially the latter. It may be described as semi-prostrate, the bright, rich yellow flowers being larger than in C. algarvense, and each bloom has a zone of dark chocolate spots in the centre, altogether a wonderful rock rose. C. algarvense is more upright in habit, the flowers are rather on the small side, yellow, with a chocolate blotch at the base of each petal. There are other rock roses, but enough names have been quoted for the beginner to make a good selection of plants that will add interest and beauty to any garden.—T. W. B.

CISTUS FLORENTINUS BY THE PATHSIDE IN THE SHRUBBERY.
It is one of the best of the rock roses.



CISTUS PURPUREUS ALLOWED TO FLOW AT WILL IN THE ROCKERY.
It makes an admirable plant for edging the rock garden path.

A Fragrant Winter-Flowering Shrub.

ALL flowering shrubs are interesting, but are doubly so when they are deliciously sweet scented and flower from December to April. Buddleia asiatica is a new kind of shrubby habit. One cannot call it a highly decorative shrub, but it has nice grey-green foliage and is covered with bloom from December onwards. The flowers, which in form are like those of other buddleias, are described in catalogues as white, but buff would be more correct, as the inside of the tiny calyx is deep orange, which gives th outside a buff appearance.—E. V.

CISTUS LORETI AGAINST A PORCH FACING SOUTH-EAST.
It grows well in such a situation and blooms profusely over a long period.

FLOWERS FOR AN UNHEATED GREENHOUSE

A Selection of Suitable Plants and how to Bring them on in Rotation.

A GREENHOUSE which depends entirely upon sun heat cannot be expected to keep out more than 3° to 5° of frost, and for this reason all tender plants must be left out of consideration. In spite of this fact a fairly good display can be maintained during the year, especially in the spring and summer. Winter is the worst period, for in addition to frosts, we have damp to contend with, and this is most difficult to hold in check. However, with care the greenhouse need not be quite devoid of flower even in the winter. A few of the early-flowering shrubs will be found useful, and although they may not bloom much in advance of their neighbours outside, the flowers will be much cleaner and brighter, while they can be seen to better advantage under glass. The well known winter Jasmine, Jasminum nudiflorum, is beautiful when protected from bad weather, and its ally, J. primulinum, is quite satisfactory inside. Both require cutting back after flowering to promote new growth, which will produce blooms next year. Rhododendron præcox and other early-flowering kinds would bloom in January, while Chimonanthus fragrans, the winter sweet, is worthy of a place for its delightful fragrance alone. Little pruning of the latter is needed except the cutting back of old shoots to keep the plant in shape. Forsythia spectabile will bloom in February, and this hybrid requires little or no pruning. Laburnum, lilac, Azalea mollis, deutzia, philadelphus (the smaller varieties) and roses could also be utilised for an early spring display. To get the best results these plants must be potted up in the autumn and the pots plunged in ashes till early December, when they are taken inside. After flowering they must still be kept in the greenhouse till the weather is congenial, say, early April, when they are plunged again in ashes for the summer. The pots will be filled with roots, so a generous supply of water will be needed, and a fortnightly application of liquid manure or artificial manure will prove beneficial. If given proper attention they will be available for three years, when they will need replacing by smaller specimens, which can often be found in the garden.

A collection of Christmas roses (helleborus), if potted in the autumn, would be a perfect joy when in flower, the spotless purity of the blooms would appeal to all flower-lovers. The sweet violet, both single and double forms, are admirably suited for pot culture, and would produce a quantity of bloom if lifted and potted up in September. Bulbs ought certainly to play an important part in the spring, when they will be in blossom in advance of those outside. Narcissus, crocus, scillas, tulips, hyacinths, etc., are potted in the autumn, plunged in ashes for six or eight weeks, and then brought into the greenhouse. Iris tingitana will be potted about the same time, but it does not need covering to induce root action. This is such an easily grown plant that another batch could be potted in October for succession. In the spring the house will be available for raising seeds, such as stocks, asters, nicotiana, alonsoa and a host of other choice annuals for filling the flower-beds later on. The seeds are sown in boxes of light soil, and until germination takes place the receptacles are covered with sheets of newspaper. This conserves moisture.

Vegetable marrow plants, ridge cucumbers, celery, mustard and cress and such like can also be raised successfully. If it is decided to fill the house with tomatoes for the summer, it is advisable to purchase the necessary plants about April and fruit them in pots 10ins. or 12ins. in diameter. Fibrous loam should form the staple of the rooting medium, to which is added a liberal sprinkling of wood ashes and bone meal. When well rooted and the first truss of fruit is set, the plants are fed with liquid manure and some special tomato fertiliser. Fumigate occasionally to destroy white fly. If tomatoes are ruled out and flowering plants are chosen, then fuchsias, pelargoniums and similar subjects will succeed. It will be found profitable to purchase a few small plants and grow them on, but the tubers of begonias can be kept intact in the dwelling-house while they are dormant and restarted in the spring. The chimney campanula, C. pyramidalis, both blue and white, produce a fine show in August if good plants are potted up in the previous autumn and brought into the greenhouse in March. This is another hardy subject much improved under glass. A small collection of chrysanthemums should certainly be cultivated. The earliest varieties will blossom in September and the last about Christmas; but much will depend on the weather regarding the success or otherwise of the latter. For the greater part of the year chrysanthemums will be in the open. When in flower the atmosphere of the greenhouse must be kept as dry as possible to prevent damping of the blooms and the loss of foliage. A few other hardy plants that will help to furnish the unheated greenhouse include lily of the valley, the best crowns from the bed outside being potted up in November. Solomon's seal and Dielytra spectabilis are lifted from the open and potted when dormant. This remark also applies to the astilbes or spiræas, and most lilies will be available for our purpose, especially auratum, Harrisii, regale and lancifolium. Good flowering bulbs can be obtained in the spring, and should be potted up directly they are received. An interesting pursuit is raising liliums from seeds, and a cold greenhouse is well adapted for this purpose. Many of these will blossom the second year.

Double wallflowers, stocks, Canterbury bells, Phlox Laphamii (a delightful pot plant), the shrubby Veronica Hulkeana, Spanish iris, such fine hardy primulas as P. helodoxa, Bulleyana, Red Hugh and the orange-scarlet Cockburniana, while polyanthus in shades of yellow or mixed are a revelation in pots when flowered in a greenhouse.

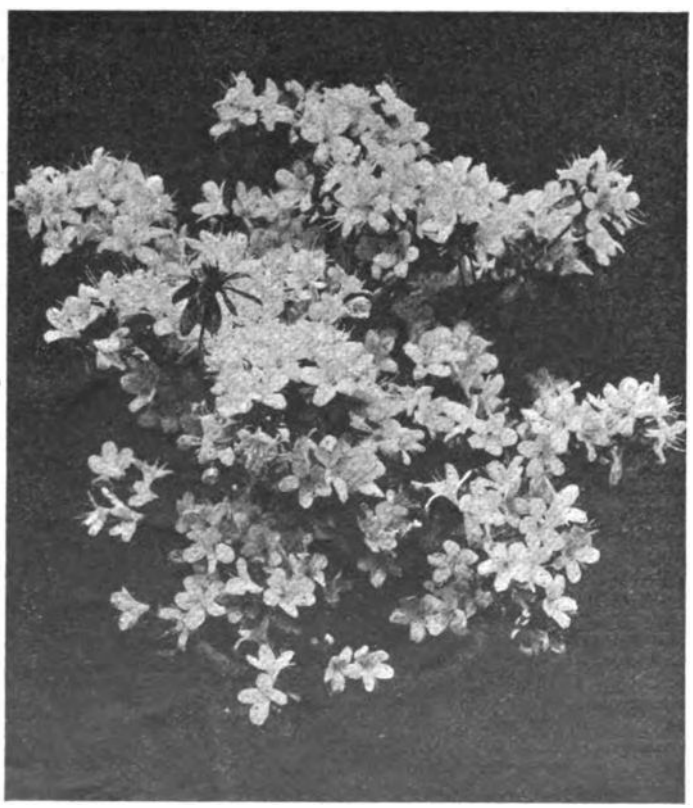
For those who wish to specialise and have something out of the common run they could not do better than try a selection of alpines in pots and pans, and, moreover, the house would be available for other purposes during the summer and autumn. It will be necessary, however, to have the plants in their receptacles the previous spring, so that they will be established by the following winter, when they are transferred to the greenhouse.

On the whole they are of easy culture, and a gritty soil will be found to suit the majority. It should be borne in mind that it will take two or three seasons to build up really good specimens. As a beginning the following are suggested, and the number could be increased as the grower became better acquainted with this type of plant. The dwarf forms of iris, such as Histrio and reticulata, are excellent for pans, a large number of the saxifrages, the various forms of Phlox subulata, particularly Vivid, the smaller narcissus, trilliums, grape hyacinths (Muscari), androsace, the dog's tooth violet and several of the primula family, such as P. rosea, denticulata, farinosa, Forbesii, cashmeriana and viscosa, while a collection of alpine auriculas would be a feature in themselves.

With the unheated greenhouse in winter it is a wise policy to take advantage of any sunshine by closing the house soon after midday, thereby retaining as much sun heat as possible. This is also necessary in the early spring, when a bright day is occasionally followed by 6° or 7° of frost.

Full use should be made of the blinds in frosty weather, and in a cool house I have covered plants with paper and saved them from damage. Careful watering must be practised, and this is best carried out in the morning, while the floors are kept as dry as possible. It is safer to have the plants on the dry side when there is any fear of frosts likely to enter the house.

T. W. BARCOCK.



ANY OF THE VARIETIES OF AZALEA MOLLIS MAKE A DECORATIVE POT PLANT FOR AN UNHEATED GREENHOUSE.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

OUR first experience of winter has been severe and prolonged. Since the beginning of November low temperatures have prevailed, and, while the country is clothed in a white mantle in some districts, it is frost-bound in other parts, and outdoor operations in the garden are at a standstill. Very little progress has been made with the planting of roses, fruit trees and shrubs, and those gardeners who have received delivery of their plants would be well advised to keep the packages intact and place them under cover in a dry, frost-proof place, and, provided they have been securely packed at the roots before leaving the nursery, there need be no anxiety as to their safety under cover of a sack or matting. Preparatory to planting steep the roots in a puddle and make hard planting the rule.

In view of the increasing popularity of the herbaceous border among amateurs, practical hints regarding the selection and culture of the plants are usually helpful, and there is an added value to the information when it emanates from one who is in close touch with the subject and has acquired a good reputation as a grower and exhibitor. Few gardeners are better able to speak on such a theme than Mr. James Currie, Barskimming, Mauchline, who for a number of years has won the principal prizes at the Glasgow Flower Show, and he was able to convey much useful knowledge to the members of the Glenfield and Kennedy Horticultural Society, who invited him to lecture on Herbaceous Plants for Exhibition at their monthly meeting held at Kilmarnock recently, under the presidency of Mr. Robert Robertson. The lecturer recommended that fifteen varieties should be grown for a twelve class, nine varieties for a six class, and six varieties from which to select three vases; and in submitting the following collections he emphasised the point that most of the sorts were also suitable for ordinary garden purposes.

Best Fifteen for Exhibition.

Astilbe Davidii	Achillea The Pearl
Aster Acris	Chelone barbata
Cimicifuga Simplex	Helenium rubrum
Helianthus Lodden Gold	Lobelia Firefly or Huntsman
Lythrum roseum superbum	Sidalcea Sussex Beauty
Montbretia Lord Nelson	Lilium tigrinum or Fortunei
Veronica subsessilis	Delphinium, any variety
Thalictrum dipterocarpum	

Nine Varieties.—Astilbe, lobelia, lilium, montbretia, thalictrum, lythrum, sidalcea, achillea and veronica.

Six Varieties.—Lilium, gaillardia, thalictrum, sidalcea, montbretia and lobelia. The above are in flower for the August and September shows.

Here are a few tit-bits selected at the lecture: The ideal herbaceous border is a double border with a grass path between. Japanese anemones should be severely left alone, as they resent disturbance at the roots. For vase decoration split the stems, otherwise the flowers will flag very soon. In winter the kniphofias have a bad habit of rotting off in the centre after snow and rain, and should be protected with their own foliage. Young plants of phloxes should be grown every year. Take cuttings in September, put them in a cold frame until April, and you will get decent flowers the first year. Scabiosa caucasica requires to be potted up and wintered in a cold frame. It is a failure in cold, wet soil, and succeeds in a sunny position in a good, well drained medium which contains lime rubble. At the close an interesting discussion was initiated by a question regarding Thalictrum dipterocarpum, and the various speakers referred to the difficulty of obtaining a true strain.

There is a proposal to hold the National Trust Show at Glasgow next year, and the wonder is that such an arrangement did not materialise before this, as the second city of the Empire is, barring Liverpool, the largest distributing centre for apples in the kingdom. In view of the ample accommodation provided in the New Kelvin Hall, it is suggested that competitive exhibits of chrysanthemums and potatoes should be incorporated with fruit. Mr. William Cuthbertson of Messrs. Dobbie and Co., Edinburgh, who is closely associated with the potato interests, is sanguine that the prize money will be raised, and the assistance of the Royal Caledonian and Glasgow and West of Scotland Horticultural Societies will probably be invited on behalf of the chrysanthemum section.

The mention of potatoes reminds me that Arran Banner is commanding the highest price since the days of Northern Star and Eldorado. In their report on the trade in Scottish seed potatoes to England, the National Farmers' Union of Scotland states that Mr. McKelvie's latest introduction is commanding £500 per ton, £300 per half-ton, £50 per cwt. and £8 per stone; while the quantity offered of Messrs. McGill and Smith's new maincrop variety, Doon Star has been sold out, except a few garden parcels, at £50 to £60 per ton in one or two ton lots, £25 per quarter ton lots, and £6 to £10 per cwt. Herald, the new earlier potato, also raised by the Ayr firm, is meeting a good demand at £30 to £35 per ton and 40s. to 50s. per cwt.

During spells of open weather, attention may profitably be given to the propagation of herbaceous plants by division. Astilbes may be increased by that treatment in autumn or spring, but the former period is preferable in a dry season. Achillea (The Pearl or Perry's White), aconites, artemisea, delphinium, rudbeckia, are but a few subjects which may be divided when the weather is open. Advantage should be taken of this opportunity to dig in a generous supply of leaf-soil and manure in the lower spit preparatory to replanting.

As outdoor chrysanthemums have had their prolonged season of bloom finally terminated by frost, which, in a few exposed districts, registered 20°, the plants that are required to provide a stock of cuttings for next season should now be lifted and planted closely in a cold frame or packed in boxes and placed underneath the staging of a cold greenhouse. Where glass protection is not available and the stools are allowed to remain in their flowering quarters over winter, it is necessary to provide a surface covering of some kind if they are intended for future use. Light sandy soil, fibre, moss litter and bracken are suitable material for the purpose; but, unless the winter is exceptionally severe, a 4in. layer of moss litter will be found an effective protection and reduce the mortality rate to a minimum. ST. MUNGO.

WHAT OUR READERS SAY

SAFER THAN CREOSOTING.

SIR,—Your reply to a correspondent in the issue of November 5th regarding the danger of using recently creosoted poles for training rambler roses, etc., suggests that many gardeners might be glad to know that charring the poles has a preservative effect similar to that of creosoting, while it has the advantage of being quite harmless to plant life. The poles, to the extent to be put underground, are simply held in or over a fire, a garden bonfire, for example, until the surface is well charred. They may then safely be used at once, without any of the delay necessary in the case of creosoting. In the tropics and elsewhere, where facilities for creosoting are not readily available, this process is much employed for preserving piles, etc., which have to be driven into wet ground, and it is found entirely effective.—M. A. S., *St. Andrews, Fife.*

MAGGOTS IN RASPBERRIES.

SIR,—In a recent issue (October 29th) of your charming paper I have observed a complaint as to the great frequency of maggots in raspberry fruit, and asking if there is any remedy for the infestation of the fruit.

May I offer you and others a suggestion which I have carried out for about thirty years and which I still practise. It is a simple one, akin to that suggested for black currant mite (big bud).

When gathering the raspberries do not strip the fruit off the stalk, but with a small pair of scissors cut off each fruit. Then pick off the raspberry and *burn each centre*. It is, I believe, in the centre that the maggot dwells, so by this method one destroys the grub instead of allowing it to develop and become a fly and so propagate its species.

Many people will jeer at this method and term it an old woman's foible. Well, so it is, but I do know this—that, many years ago, the raspberries in our garden were horribly wormy, but now I can pick 4lb. or 5lb. of fruit and not find more than two or three grubs.

By *personal* persistence in the above plans I believe I have greatly lessened the grievance. —ANTI-GRUB, *Huntingdon.*

CARE OF TOOLS.

SIR,—The article on "Care of Tools" in the October 29th number leaves out the busy gardener's best friend, fresh quicklime. I keep two large pots of it in the tool-room, and all tools are kept in them. It gradually becomes air-slaked and powdery, and is changed every month or so and used as fertiliser. Everyone knows the capacity of fresh lime for absorbing moisture—it keeps the tools clean and shining as brightly as if polished. Dibblers, small hoes, rakes, hand-tools, even scissors, sometimes are left permanently sticking in the dry lime and never have a spot of rust. Its advantage over oil or grease is that they are always clean and ready for use.—R. R.

USE FOR OLD RASPBERRY CANES.

SIR,—A recent suggestion dealt with the use of dried flower-stems of herbaceous perennials for supporting plants. Many owners of gardens cultivate raspberries, and I find that the old canes when cut down at the end of the fruiting season are even more serviceable for the purpose named, since they have a prickly habit which assists greatly in supporting the young plants. Particularly are the canes useful in supporting dwarf peas, the tendrils of which readily grasp the thorny sides of the canes. The

Digitized by Google

latter, once dry, are very rigid, and are not so liable to rot as some of the stems of herbaceous plants. In a garden where annuals are a feature the expense of staking is quite an appreciable item unless small twigs or branches of trees are available, and these are not always so regular in shape as raspberry canes.—LEONARD PECK, *Seaford.*

HOW TO BEAUTIFY A HEDGE.

SIR,—In my country garden there is an old yew hedge which is in full view from the windows of the house. For a long time it was a perpetual eyesore, as it showed signs of far-advanced age. Its lower branches were thin and bare, and there were large dead brown patches in various parts of it. A narrow border in front of it was quite useless. Seeds sown in it never came up and the hardiest plants dragged out a short poisoned existence and soon disappeared. Even weeds avoided it!

An aged landlord, whose gardening ideals were as conservative as his politics, refused to allow me to have it rooted up and replaced with the low stone wall garden for which my soul longed. "It had served his time and his father's before him; he didn't hold with these new-fangled gardening notions, and, anyway, you knew where you were as long as you stayed where you were." So that ugly hedge, alas! stayed where it was and troubled my gardening senses exceedingly. Your readers may care to know how I grappled with the problem and turned the unsightly nuisance into a thing of beauty.

The wall ran north and south. In the narrow border on the sunny side I sank nine 15in. flower-pots, filled with a good compost of garden soil, loam, leaf-mould and a little sand. I sank a couple of pots on the shady side in the same way.

In Nos. 1, 3, 5, 7 and 9 I planted a clematis (Jackmanni superba), Eccremocarpus scaber, a winter-flowering jasmine, a small-leaved ampelopsis and the wild black bryony. In Nos. 2 and 6 I sowed the Morning Glory convolvulus (blue) and canary creeper, and in Nos. 4 and 8 I put polygonum and Solanum crispum. In the two shaded pots I sowed the scarlet tropæolum.

The result was delightful. The climbers completely cover the hedge, and from the jasmine in the winter to the blaze of the scarlet Virginian creeper in the autumn it is a mass of foliage and blossom, and the hedge is one of the special features of my garden.—G. H., *Northampton.*

A FRAGRANT FREE-FLOWERING SHRUB.

SIR,—Abelia chinensis is a beautiful shrub—one to be possessed by all who love fragrant, free-flowering plants. True it is not strictly hardy, save in the warmest of gardens and where the soil is light. But it will thrive with the minimum of protection in the average garden—such as a practically cold greenhouse, or outside in a southern nook, given the protection of a mat hung across it or laced over with bracken fern, or such materials, in frosty weather. I grow it in the cool greenhouse, the garden here being cold and devoid of a warm corner suitable. Planting out is not essential—whether given an outside position or grown under glass—pots of 10in. diameter will grow capital plants of 3ft. 6ins. high and more, with proportionate bushiness. The recognised height of this abelia is 5ft. to 6ft., but to attain such the growing site has to be of the most favourable.

This rock abelia, as it is occasionally called, flowers in clusters at the ends of the growths, the colour taking on a pale blush tint when open a little time, while the evergreen foliage reminds one of the myrtle plant. Pruning is rarely advisable, simply a little thinning of the tiniest twigs should the shrub get too thickly packed. My biggest plant here has not been touched for three years or more and it has been, for several weeks past, laden with the sweet smelling blossoms, quite a good sprinkling of which still remain. Those who wish to do so can make this plant to resemble a climber by tying in to a trellis or wall its longest shoots; and this is quite a good way to grow this subject as distinct from bush form.

Abelia chinensis is a native of China and was introduced in 1844.—C. T., *Ampthill Park.*

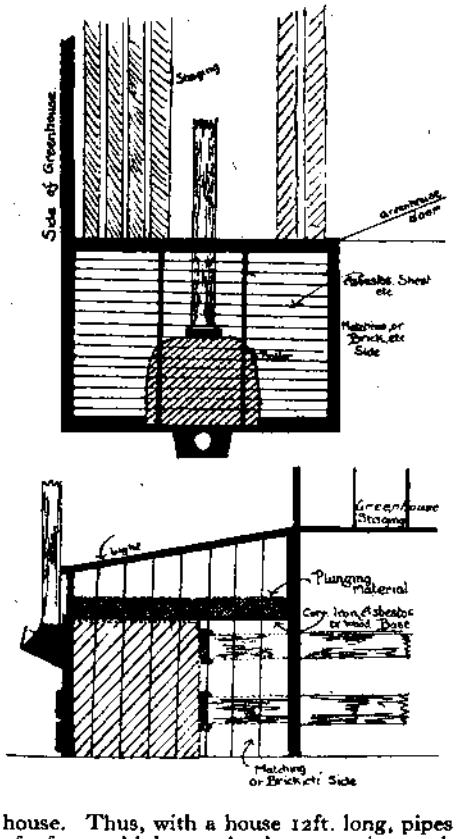
HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the Contributors.

THE HALF GUINEA HINT.

How to Make an Economical Propagating Case.

Amateurs possessing a greenhouse who intend installing a coke boiler may find the following useful. The orthodox method of installation is for the front plate of the boiler to be let in flush with the outside of the



house. Thus, with a house 12ft. long, pipes of 9ft. would be used—the expansion tank and body of boiler utilising the remaining space.

By using—for a 12ft. house—two pipes of 6ft., or one each of 7ft. 6ins. and 6ft. (for flow and return), it will readily be seen that the front of the boiler is from 2ft. to 3ft. outside the house. The sides may be filled in with matchboarding and a sheet of asbestos, etc., placed horizontally immediately over the boiler, the whole being finished off with a frame. By placing a thick layer of peat moss, kept damp, over the asbestos, a satisfactory striking pit is the result, the pots being plunged in the peat.

The obvious advantages to the amateur with limited means and only a small house are the initial cost of a propagating case, upkeep of same and saving of valuable space in the greenhouse itself.—*S. V. Redman, Surbiton.*

Young Fruit Trees.

Young fan-trained fruit trees often develop one or two branches at the expense of the remainder, resulting in unsightly, lop-sided specimens. In this case spare the knife: unfasten the branches from their supports, re-tie the weak-growing shoots in a perpendicular position, while the stronger and more vigorous ones are brought down and tied to the horizontal according to the degree of growth. The tendency is then to invigorate the weak shoots and retard the robust growths. Re-train the branches into the desired positions during the next dormant season.—J. W. H.

When Pruning Fruit Trees.

In addition to the ordinary pruning saw, I find that a joiner's panel saw is invaluable when pruning fruit trees. This has a thin blade of about 10ins. length, which screws into a pear-shaped boxwood handle. For thinning crowded fruit spurs, cutting out old wood from flowering shrubs, etc., it cannot be beaten. The thin blade will go where the ordinary pruning saw cannot be used without doing harm.—W. G. E.

Mending the Greenhouse Pipes.

At this time of the year, when the heat is being increased in the house, it is no uncommon thing for the pipes to exhibit a burst, and it may be of interest to others to know how such a contingency may be easily and effectively dealt with without running off the water or reducing the fire heat. As soon as the crack is observed, obtain a pound or two of ordinary builder's cement, and with each pound mix in a dry state 1 oz. of common washing soda. Next fix a wooden or strong cardboard box around the pipe so as to form a mould, then add a little water to the cement and soda, and after mixing it into a thick paste, pour it into the mould. This mixture will be found to set very quickly and will make a watertight joint, but to be successful it is important that the ingredients be first mixed together while dry, and that it is used as soon after the water is added as possible.—R. K.

A Binding Case for "The Garden."

As the articles and hints which appear in THE GARDEN weekly are very often useful weeks and months afterwards, it is best to keep the weekly copies of the paper in a handy form. The writer did this by making a binding case from two pieces of strawboard (same size as THE GARDEN) and a piece of binder's cloth.

The wires were abstracted from each of the issues of THE GARDEN for January-June (and then July-December), the covers and advertisement pages removed and the remaining pages of text matter were punched with two holes to take the screw binder, which could be bought from any stationers for 6d. Holes were also punched in the binding case and the screw binder passed through the case and the twenty-six issues of THE GARDEN and then screwed down. In this way each six months issues can be kept for quick reference. Additional interest can be given to the volume by cutting out the coloured illustrations off the front cover and mounting them on brown paper and inserting in the binder between each issue. The whole cost of this plan was 1s.—A. R. D.

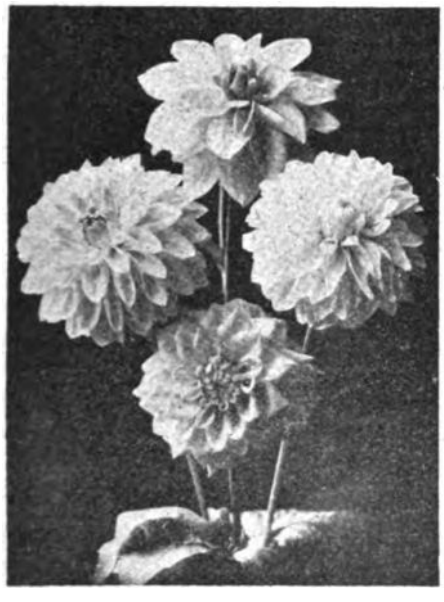
NURSERIES OF THE BRITISH ISLES.—XII

MESSRS. CHEAL AND SONS, LIMITED, CRAWLEY.

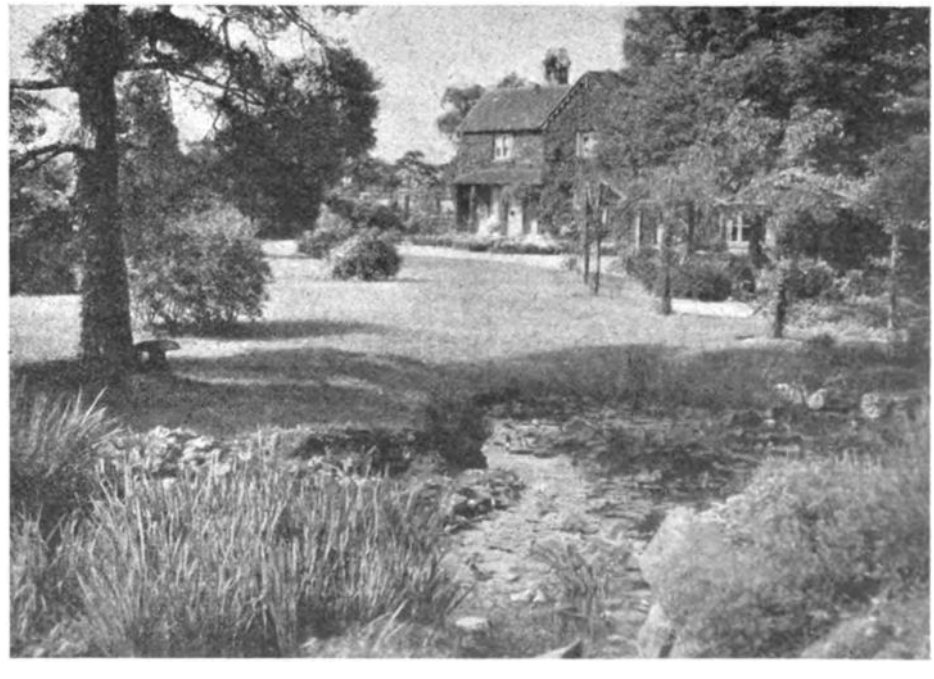
AMONG nurseries of the south, there are few which can lay claim to have established such a world wide reputation within the short space of fifty years as that achieved by Messrs. Cheal and Sons, Limited, of Crawley, Sussex. This firm is only fifty-six years old and yet within that period they have built up a reputation as fruit growers, landscape gardeners and general nurserymen that extends all over the Continent as well as in this country. The secret of their success is largely due to the initiative and enterprise that have been shown by all the members of the firm, and especially to the activities of the two original partners, Mr. Joseph Cheal, V.M.H., and Mr. Alexander Cheal, who founded the business in 1871. Messrs. Cheals is a firm that has kept abreast with the gradual changes in horticulture. They have never been slow in altering their methods to suit the changing conditions of the times and in that way have gained the respect and thanks of many thousands of customers. They have ever been eager to assist in promoting in whatever way they could the cause of gardening and horticulture in this country. They have endeavoured to specialise in certain aspects of nursery practice and in the growing of certain kinds of plants as a means to popularise these plants and bring them into public favour, and that they have succeeded in their object few will gainsay. They have contributed much to the general store of horticultural knowledge, not only as a firm, but also as individuals, and in this respect we would single out the name of Mr. Joseph Cheal, the senior member of the firm, who has done so much to promote interest in fruit growing in all gardens and also with his magnificent work in connection with the dahlia. It is to this firm that all gardeners owe many of the finest varieties of dahlias in cultivation to-day, and also the fact that they are represented in almost every garden. A flower or a plant seldom becomes popular unless many years are spent in trying to mould and fashion public taste in that direction by producing a plant that is certain to attract. It is now, when the dahlia has achieved the rank of one of our favourite garden flowers, that Mr. Cheal can see the reward of his labours.



FOUR NEW SMALL DECORATIVE DAHLIAS RAISED BY MESSRS. CHEAL THIS YEAR.
These are Belle Mauve, Omesan, Mrs. F. C. Selons and Topaz.

AMONG THE DAHLIAS AT MESSRS. CHEALS, IN SEPTEMBER OF THIS YEAR.
The double border contained thirty-six varieties of mignon dahlias.

The nurseries are situated on the main London-Brighton road, some two miles from the town of Crawley, and we know of few situations which could prove so favourable from the standpoint of attracting public attention. It is safe to say that they receive thousands of visitors a year and they welcome a visit to the grounds. When the business commenced the nursery occupied a few acres of their father's farm, and three men were employed. As the years went on and the business grew, the acreage was increased, till now they have extended on to the opposite side of the road and in all take in about a hundred and twenty acres, employing a staff numbering a hundred and forty. There were many difficulties at the beginning, but by dint of much patience and hard work these were overcome, till the nursery was in a sound position. The cultivation of fruit trees, herbaceous plants, ornamental trees and shrubs had the first consideration of the firm, but as time went on a landscape department was added: this has now become probably the most



AN ATTRACTIVE GARDEN VISTA AT THE NURSERIES, SHOWING A SMALL WATER LILY POOL WITH A PORTION OF LAWN AND ROCK GARDEN.

Digitized by Google

important side of the business. This department was for many years under the management of Mr. Joseph Cheal, who built up a splendid reputation, and his work is now ably carried on by his sons, Mr. Ernest Cheal and Mr. Arthur Cheal, who have charge of this department. They have now a wide reputation all over the country and on the Continent for important works in this department, and it is interesting to note that they have carried out some large works in remodelling old castle and mansion gardens.

The progress and development of the landscape department has led to the consequent increase in the volume of nursery work, as the two departments work hand in hand. All trees and plants that are required for use in their garden schemes are supplied either from the nurseries at Crawley or from the small nursery at Pulborough, which covers about fifteen acres and is chiefly used as a supply ground to the main nurseries to keep up the stock. All styles of landscape work are undertaken, either in laying out new gardens or in remodelling old ones.

At the time of our visit, over four weeks ago, a start was being made with the despatch of plants to meet autumn orders and we were enabled to see how well organised is this side of the business. All orders are checked and rechecked and well packed, and only the very best of material is sent out. It may interest readers to know that visitors to the nurseries can go round and make their own selection of plants. If they think one plant out of a batch better than another, they can label it and it will be sent at the proper time. This is an excellent way of doing business, since both parties are satisfied and it makes for better harmony between customer and producer.

We were much struck with the neat, trim and tidy appearance of the nursery itself, despite the very bad season for weeds. The ground is well laid out and organised. The stock is divided off into compartments, each in charge of a foreman, who has a knowledge of every plant under his charge. Each section is separated from the other by means of well furnished hornbeam hedges, which seem to thrive well in the clayey soil of Crawley. It does much better there than beech. The hedges also assist in protecting the plants from undue exposure to gales. The stock carried is a large and extensive one and is of a high standard of excellence. Every attempt is made to produce robust and healthy plants of good quality and which consequently will succeed in any garden to which they may be transferred. Some forty acres of the nursery are devoted to fruit alone, and all the leading varieties of apples, pears, plums, cherries, gooseberries, raspberries, currants, etc., are represented. The quality of the stock is excellent. The trees are healthy and well grown, while due consideration is paid to the type of stock on which the varieties are grown, in order that results may be compared and the very best material sent out. It would appear, too, that fruits, especially apples, take on a distinctly fine and rich colour, which may be possibly due to the amount of iron in the soil. The presence of salts in the soil is said not to affect the colouring of apples to any extent, but certainly at Crawley there would appear to be something in the theory.

A wide and varied collection of ornamental trees and shrubs, including conifers, is stocked, and the size and quality of several of the large batches of plants were remarkable. A particularly large stock of hybrid rhododendrons and azaleas are kept, while special interest is taken in veronicas, of which a large stock of New Zealand species is held, heaths, flowering cherries and plums and many other ornamental kinds too numerous to be detailed here. Conifers, both for ornamental purposes on the lawn and rock garden and for forestry purposes, are grown in variety and in every case the plants are of a convenient size for transferring to the garden. Many choice varieties of ornamental dwarf conifers are to be seen, and readers who are interested in conifers would find a visit interesting as well as instructive. Climbing plants and hedge plants are also to be found in variety and suitable for various aspects and soils. The flowering shrub department is a flourishing one and the stock is thoroughly up to date, embracing all the new and more modern introductions. Of interest to the amateur are the ornamental shrub borders laid out in the nursery to show how shrubs may be employed in the garden, giving ideas on how they may be grouped and the kind to use to obtain different effects. These borders, as well as lending beauty to the general lay-out of the nursery, have a definite educational value. Roses, too, are grown in variety, and it suffices to say that all kinds are grown and almost every modern variety is represented. At the time of our visit the polyantha and standard roses, grown on briar stock, were particularly good. We were informed that the use of rugosa stock for roses has practically been discontinued except in the case of a few varieties, and the chief stocks used are briar and laxa, which undoubtedly are to be preferred for all general purposes.

ONE OF THE WELL PLANTED SHRUB BORDERS IN THE CENTRE OF THE NURSERY.

A large collection of hardy plants, embracing herbaceous and alpine varieties, are grown. All the leading kinds are included and there is a wide selection from which the intending planter may draw. In the nurseries the visitor can appraise, first hand, the decorative value and usefulness of all the varieties, since they are included in herbaceous planting schemes which are on view at the nurseries and they can thus be compared one with another; also a sample rock and water garden may be seen.

It is when we come to the dahlias, however, that some of the outstanding work of the firm is noticed. Reference has already been made to the work done by Mr. Joseph Cheal in this connection, so ably assisted by Mr. Holton, who for many years had charge of this department, and how their efforts have been so successful. The type known as the mignon dahlias, now so popular for bedding purposes, were introduced by the firm more than twenty years ago. They are admirable for producing bold colour patches in beds or in borders, especially as an edging, since they only reach some 18ins. in height. Moreover, their flowering period extends from early July until the end of October. The Star class of dahlias was also raised and introduced by Messrs. Cheals about fourteen years ago now and the appearance of flowers of this type has probably added more to the popularity of the dahlia than anything else. The star dahlias in their new varieties are now general favourites. They are free-flowering and of robust habit and are excellent either for garden or home decoration. New varieties make their *début* every year and each year the new varieties seem to outdo the old. One of the novelties in this class for 1928 is Rye Star, with blooms of a coppery orange tipped with rose. This variety was recommended for trial at Wisley by the R.H.S. Floral Committee. Attention is also paid to the other types and here again Messrs. Cheals are making their interest felt by the production of numerous new varieties every year. In the camellias or small decorative class four of their novelties for 1928 are, Belle Mauve (pale mauve), Omesan (clear yellow), Mrs. F. C. Selons (salmon rose) and Topaz (a brilliant scarlet). All are over 4ft. in height, with strong, wiry stems, which carry the flowers well above the foliage and thus give the plant a handsome appearance. The charm or miniature peony, decorative, cactus, peony-flowered and collarettes are all grown, and an extensive range of varieties is offered in every case. All dahlia lovers should certainly make a point of visiting Crawley during early autumn to see the dahlia borders. This year the display was magnificent. Thirty-six mignon varieties, each in bold groups, form the foreground of a double border each side of a grass path, while the background was composed of a ribbon of Crimson Flag and the taller White Star, which made for a most effective combination. It was an object lesson in the decorative value of the dahlia in the garden.

The firm has numerous other activities and we advise all readers who may be interested to take advantage of the invitation offered by the firm to visit the nurseries in order to appreciate the pleasant lay-out of the grounds and to learn something of what Messrs. Cheals are contributing to the world of horticulture.

THE FRUIT AND KITCHEN GARDEN

A Few Hints on Pruning Young and Very Old Fruit Trees.

WHEN the weather is open the pruning of fruit trees may be done. The following hints will be helpful to inexperienced cultivators. Young specimens recently planted for training on walls or wooden fences should be left untied or unnailed until the early part of spring, so that the roots may settle down in the loose soil. If the branches are tied up too soon the roots may be suspended in the soil, the latter settling down away from them. Usually these wall specimens possess from five to nine long shoots, and it will be safe if the ends to one-third their length are cut off. Young trees planted as bushes, pyramids, espaliers or standards should be treated in a similar way as regards pruning. It will be advisable to place stakes to every one, because trees blown to and fro get very loose in the soil and root action is retarded. The stakes must be so placed that they will keep the trees steady while not hindering the due settlement of the roots in the soil. Very old trees, especially those that have been neglected, require very careful treatment as regards pruning. Injudicious cutting away of branches will result in the removal of many fruit buds. Most of the latter are borne on the ends of the extreme outside branches and careful thinning out of these branches will do a lot of good. Quite plump buds may be found on the ends of shoots, varying from 5ins. to 12ins. in length, and these shoots should be retained as the cutting off may do away with many valuable fruits. Some old, stunted trees may be greatly strengthened by rather severe cutting out of branches so as to induce the growth next year of strong shoots. These kinds of trees need some attention to their roots as well, feeding with new loam, manure and, while growing, doses of liquid manure.—CHRISTCHURCH.

Protecting Broccoli During Early Winter.

BROCCOLI are much hardier than cauliflowers, but even so in severe winters the plants may be killed or so much crippled that they soon become useless. After the recent long spell of cold, rainy weather the whole of each plant, stem, main leaves and roots too, are more tender and more sappy than usual. When in such condition hard frosts will have more effect upon them. The tenderest part of a maturing plant is that portion of the stem just below the main leaves. A covering of ordinary soil will preserve the stems. Late varieties—those plants that will "turn in" during April, May and the early part of June—must not be disturbed as regards their roots. Allow them to remain in an upright position or inclining a little towards the north while you heap up the soil so that it touches the lower leaves. Mid-winter varieties should be treated a little differently. Take out a spadeful of soil on the north side of each plant, depress the latter by placing a foot upon it if working single-handed, then drop the soil on the stem. If frost comes plants so treated will be safe. Their white heads, or curds, will not be frozen very much, or, if they are, the thaw that comes will be gradual, and discoloration will not be such as to spoil the broccoli for cooking. If any readers do have frozen broccoli, kale or any kind of winter green plant and are obliged to cut such when in a frozen state, soak in cold water in a cold place for several hours or until the frost disappears. The plant then will be quite fresh and sweet.—G. G.

Present Treatment of Maincrop Celery.

MANY fine rows of celery plants are successfully grown through the summer and autumn months and then lost in mid-winter. It is not exactly the mid-winter treatment that is at fault, but the late autumn treatment, which has not been such as to prepare the plants for withstanding the rigours of winter. The losses are greatest where the plants are grown in double rows. Inexperienced cultivators should always grow their plants in single rows and learn to manage them before they adopt the plan of growing two rows abreast in one trench. The final earthing-up should be done now. Select a dry day for the work and, also, when the soil is fairly dry, too. Reduce lumpy soil to a powder so that when placed to the rows of plants it will fit closely to the stalks near the top. Press the soil in firmly between the two rows of plants and have a rather sharp ridge of it between the rows. It is when there is a depression in the soil there that water enters constantly and freely, and this causes the sticks to rot. Earth-up so that some of the top leaves are covered; it does not matter if they are lost. Then loosen the soil between the rows and have ready at hand some dry litter in case severe frosts come suddenly.—HANTS.

Winter Care of Peaches and Nectarines.

PEACHES and nectarines, whether growing under glass or out of doors, should be looked over carefully each winter while they are dormant in case any destructive insects may be lodging about the branches. Two common sources of injury to peach trees are found in scale insect and mealy bug. By far the best time to deal with these pests is in the winter, for at that season strong insecticides can be used which at any other period would cause injury to leaves, shoots and fruits. All trees, whether infested or not, are the better for being sprayed with a caustic wash. A very suitable preparation is formed with half a pound of caustic soda, half a pound of commercial potash and five gallons of water. Keep this mixture away from the clothes. This not only kills insects, but also destroys the moss and lichen which harbour the pests. When the insects can be seen an additional step would be the brushing of the branches with a paraffin emulsion prepared in this way: Add one pound of soft soap to one quart of soft water. Boil for half an hour, take off the fire, and then add half a pint of ordinary paraffin. Dilute with eight gallons of water and stir up well when using. If desired, the mixture may be applied with a syringe, but it should be used freely to be effective. Pay special attention to the young flower-bearing shoots, as it is most important that these should be perfectly clean.—L. B.

Planting Fruit Trees.

THE best time to plant fruit trees is some time during the month of November when the soil is still warm and atmospheric conditions are favourable to root growth.

The ground for planting should be prepared several days previously, the holes for the trees being got out two spits deep, the top spit being placed on one side of the hole and the bottom spit on the other.

Upon the arrival of our trees from the nurseryman they should be unpacked in a shed, and if we are not ready to plant should be laid in the ground, covering the roots with soil until such time as planting may be done. If frosts or excessive wet intervene it is advisable to place straw or bracken over the roots, covered with soil, to act as a shield.

Choose a period when the weather appears to be settled for planting. Take the trees for planting and examine their root systems. Any roots which are damaged or bruised should be cut back to healthy tissue and the cut made so that the cut surface will be away from the top of the groud when planting. Roots such as tap roots going vertically downwards should be removed entirely, and long branch roots slightly shortened.

One great mistake often made in planting fruit trees is in not getting out a sufficiently large hole to take the roots without curling or bending them. Be sure to make your hole large enough to take the root spread out.

The ground below the bottom spit should be broken up with a fork and the bottom spit replaced in the form of a slight mound, *i.e.* rising in the centre and falling away slightly to the sides. If the soil is good soil, no additions need be made to it; but if it is poor, the addition of loam and lime rubble plus some wood ashes to the top spit will materially assist the trees.

Having replaced the bottom spit, a stake should be driven in just a little to one side of the centre. This stake is the one to which the tree will be tied, and its length will depend on the tree to be planted. It should be driven 1ft. to 1ft. 6ins. into the soil. It is a bad though common practice to stake after planting, but this is liable to injure the roots. The bottom spit should be covered with about 2ins. of prepared soil, and the tree, with its roots spread out, placed on top of this. Work the prepared soil well between the roots and take great care that the tree is not planted too deeply. As a general rule, the tree should not be planted deeper than it was in the nursery row, and the junction of stock and scion should never be covered. When the roots have been covered the soil should be firmed by treading and soil added to bring up to about 3ins. above the surface of the roots.

A light top mulching of stable manure placed on the surface of the ground materially assists the tree, as it helps to keep the soil moist and warm and is a protection against frost. The tree may be loosely tied to the stake at once if there is likelihood of much wind, otherwise it is best to leave it for a week or so until the tree has had time to settle.

Remember—never plant in wet weather, and never plant too deeply.—K.

Rhubarb all Winter.

AS soon as the stalks become soft rake them off the rhubarb crowns and dig out sufficient roots to last throughout the whole winter; do not take them inside, however, but simply turn them upside down to expose the roots, this proving, in some mysterious way, helpful to the forcing process. Take a few roots inside as soon as demand makes itself known. Place the roots close together and packed in sifted leaf-mould or soil under the stage of the greenhouse and keep out most of the light by placing mats or sacking in front. Or place them in boxes and keep these near some source of heat, the interior of the boxes being again in darkness; a warm cellar is quite all right for this, or the boxes may be laid directly over or in the middle of fresh, warm manure. Rhubarb comes away quickly when placed near heat, but care must be taken to see that the forcing process is not overdone, otherwise the stalks will be too thin and spindly. See that the roots and the mould in which they are packed are kept moist, as plenty of water is needed to keep the stalks fleshy and sweet. Introduce fresh roots whenever the first show signs of losing energy.—H. H. A.

OUR SERVICE BUREAU

All communications should be addressed to the Service Department, THE GARDEN, *20, Tavistock Street, Covent Garden, London, W.C.2. A stamped addressed envelope and the coupon, that will always be found in each issue, must be sent with the enquiry.*

We have selected the following enquiries with their answers, as being of more general interest, and therefore worthy of publication.

Dwarf Conifers for Tubs.

Being anxious to grow some of the dwarf conifers in tubs, i.e., *12in. in diameter, will you kindly give me names of some that would be suitable and the best soil, etc.?—W. L. S. L., Cornwall.*

We suggest that you grow some of the following dwarf conifers, which are suitable for your purpose: Cupressus Fletcheri, C. obtusa compacta, Picea excelsa Clanbrassiliana, P. e. Maxwellii, P. e. pygmæa, P. orientalis gracilis, Juniperus hibernica compressa, Thuya occidentalis globosa, T. Spilmannii, T. umbraculifera. The most suitable soil is a fibrous, loamy soil to which a little peat and leaf-mould with a little coarse sandy grit has been added.

Plants for a Lily Pond.

I have a lily pond in my garden and wish to grow some decorative reeds or rushes in it. Would you be good enough to advise me as to a suitable variety for this purpose?—F. P., Westcliff-on-Sea.

Some suitable aquatics for your lily pond are: Butomus umbellatus, the flowering rush. This can be grown in 1ft. of water. The leaves are 2–3ft. in length. Cyperus alternifolius, umbrella grass, can be grown in shallow water. Cyperus longus, ornamental grass like species in length. Glyceria aquatica spectabilis, an effective variegated grass. Juncus articularus, a pretty rush. Scirpus zebrinus, one of the bulrushes, and Sagittaria japonica plena, one of the arrowheads. There are many other plants that can be grown either in shallow water or at the water's edge.

Roses Attacked by Aphis.

I venture to send some rose leaves which have been badly affected this season. I am not sure if they are attacked by insects or fungi. Some trees have been so badly attacked that I have stripped off the whole of the leaves and burned them, so spoiling the appearance for this season, in the hope of stamping out the trouble. Mme. Butterfly has been one of the worst, but the blooms have been quite beautiful, and I am still bringing in buds which open well in water.—K. S., Clacton-on-Sea.

The mottled appearance of the rose foliage sent for our inspection is due to one of the plant bugs—the rose leaf-hopper—and aphis. The bushes should be sprayed periodically throughout the growing season with nicotine-soap wash. A special endeavour must be made to direct the wash to the undersides of the leaves, for it is on this surface that the insects congregate. The immature and wingless leaf-hoppers appear in early July, when spraying must be commenced as soon as their appearance is noted. The mature and winged adults are very active and fly away as soon as the bush is sprayed. Spraying for aphis must be commenced in May, using the same material.

Whitethorns from Seed.

I should like to grow whitethorns from seed, and I should be much obliged if you could give me any hints as to the best time and methods of sowing the seeds. Would it be better to raise them in a frame or in the open?—M. E. M., Redhill.

Put the fruits of the whitethorns in wet sand now to rot the fleshy portion. If only a hundred or so plants are required, sow in a box in a frame during March, or for large numbers sow outside in drills. Rub the sand and fruits through the hands to separate the outer portions. If there is not too much sand the whole can be sown; it will help in the thin distribution of the seeds.

Remedies for Apple Scab.

Would you tell me what is wrong with the enclosed apples and suggest treatment next year if the complaints are not due to the abnormal wet season with its accompanying troubles? (A) *is a Lady Sudeley, of course very small. All the apples on the trees this year, except one here and there that was sheltered, were rough in the skin like this.* (B) *is a small Irish Peach, cracked, as were most of the apples on this tree. What is the cause and remedy?—G. H. P., Beauly.*

Both the apples you send are attacked by the apple scab fungus disease. The bad season has, of course, encouraged this disease, but it is likely to appear in any year. The remedial measures to adopt are to spray the trees with Bordeaux mixture immediately before the blossoms open in spring, to spray with lime-sulphur—at summer strength—immediately the blossoming is over, and to prune out as much diseased wood as possible in winter. Diseased wood may be distinguished by the cracked and blistered bark where the fungus is present in the tissues. A quick cure must not be anticipated, for if the disease is deep-seated it may take several seasons of the above treatment to get rid of it entirely, though the spraying should keep the fruit fairly clean. We rather question if the variety labelled B is Irish Peach, though the specimen sent may have been a late fruit. Irish Peach is generally eaten in July and August, as you may know, and the apple sent was still fairly hard.

Perennials for a North Border.

Can you suggest a few low-growing plants that would be happy in the following conditions? Bed facing north, house behind it, and flagged surround to house, with slight fall towards the bed. Damp, from rainfall, draining from the flags into the soil. No trees overhead, and plenty of light and air, but scarcely any sun, owing to the house shading it. A little sun, in early morning, reaches it from the east, and a little in late afternoon from the west. Cold and windy in winter months. Grass lawn in front, trees beyond. I thought that possibly, with suitable soil, a couple of half-standard hardy roses might do at either end of bed; but what to plant between? Violas, I suppose, would find it too wet and sunless.—R. D., Oxton.

If you can raise the border a little, both violas and pansies would grow in it. For spring, wallflowers and myosotis, also a few narcissi would do well. Fuchsias and tuberous begonias would succeed in the summer. Blue-flowered vinca (periwinkle) and St. John's Wort would both form permanent occupants and succeed. Two weeping standard roses should do well, the variety Albéric Barbier being very charming as such.

Treatment of Young Peach Trees.

Last spring I planted three peach trees against a wall (6ft.) facing east. They have made a lot of growth to height of wall. Will they require pruning and when; also when is the right time to spray against leaf curl? On one of the main branches gum is oozing out from where the leaves were attached to a length of 6ins. or 8ins. Will it seal itself or must I treat it? They were disbudded at the time you recommended. Are peach trees fertile on their own, or do they rely on other trees?—R. R., Chelmsford.

The time to prune them is now. You should select the best growths to train in as main branches and shorten the young extension growths of these by about one-third. Other young shoots should be trained in wherever there is room and from these only the top inch or two of unripened wood should be cut off. As the growths have already reached the top of the wall you must bring the branches down training them out so that they extend laterally, of course keeping the trees balanced and well shaped. The time to spray to prevent leaf-curl is in February, when the buds are just swelling preparatory to "breaking" into leaf but before any sign of "breaking" shows the best mixture to use being Burgundy mixture. The gumming will probably cease of its own accord as the tree settles down, but if it is bad and the shoot can be spared, cut it clean away. It is quite possible the tree is growing too rankly. Young peach trees are inclined to make too much wood and the remedy for this is to lift the tree, prune back the roots and replant in the same hole. This can be done now—the sooner the better. Peaches are self-fertile and do not rely upon cross pollination with other varieties for good fruit setting.

Pruning Neglected Apple Trees.

I have several apple and pear trees, the youngest apparently about eighteen years old, which have evidently been badly neglected for the past ten years or so. They have made a lot of tangled growth and long, upright shoots, but fruited well this summer. Could you outline the way I should prune them during the winter?—F. C. H., Enfield.

You should get the apple and pear trees pruned as soon as possible now. The first thing to do is to cut away the tangled and crossing branches that choke the centre of the tree. This should leave the branches well spaced and the centre of each tree fairly open. When doing this thinning, be careful to cut back to a side branch or to the stem, so that no snag or stub of wood is left to die back. It would be well to pare smooth every cut made with the saw, and then cover the surface of each with lead paint. With trees some eighteen years old very little shoot shortening should be required, and beyond cutting back to two or three buds, and young shoots that are cramped for space, little further is necessary. The long growths will "spur up" and fruit well without any drastic cutting. Of course, you will aim to keep each tree shapely and balanced, but remember that very drastic pruning is likely to hamper fruitfulness, and to promote rampant growth, which is not wanted. By "thinning-out" each season you should soon get the trees into good trim again.

Celery Rust.

Could you tell me what is the matter with the celery leaf enclosed, also what remedial measures I can adopt? I have put soot, lime and sulphur, separately, and still it spreads.—H. H., Hereford.

Your celery plants are badly affected with rust. The disease is found in the seed, and you should obtain a guarantee from the firm from whom you obtain it that the seed has been treated specially by them. In your case, judging from the specimen sent, there is no cure. Next year grow the plants on fresh ground, after liming it, and spray lightly with Bordeaux mixture as soon as any sign of disease appears.

THE GARDEN

THE IDEAL GARDENING PAPER

Vol. XCI.—No. 2922 Saturday, December 3rd, 1927 Price TWOPENCE

IT is now when the thoughts of all gardeners turn to the beauties that spring will bring forth in the garden. An attempt should be made on the part of every amateur to visualise the results of his autumnal planning and planting. Nothing should be undertaken in a haphazard way. Unless the amateur knows his plants, their habits and their colourings, it is better to plan out his ideas on paper rather than to juggle with the plants *in situ*. Only professionals can do that with success. This illustration shows what may be accomplished by careful planning in a front garden. The bed of brilliant May-flowering Tulips makes a bright splash of colour in the mass. Their colours harmonise and tone in with the surroundings—for example, the Clematis montana over the doorway. The planting of all May-flowering Tulips should be completed to ensure an attractive display during next May.

THE GARDEN

VOL. XCI.—No. 2922. DECEMBER 3, 1927. PRICE TWOPENCE.

A WINTER CORNER

THE ideal "winter corner" is a nook that gets all the sunshine available and no cold winds, and is not much in evidence from the rest of the garden, for there will be a good many months of the year when it will have little to show. Its "lay-out" must, of course, depend on its size and contour, but the paths should be of brick or stone, so that one may walk dry-shod in wet weather; the beds and borders should be well raised to ensure good drainage, especially if the soil is on the heavy side; and at least part of the area should be enclosed by walls or a high, close fence. Against this should be grown Chimonanthus fragrans, the winter-sweet; Jasminum nudiflorum; Garrya elliptica; the deliciously scented Lonicera fragrantissima and L. Standishii; and Hamamelis arborea and H. mollis, with their tufts of yellow, spider-like flowers. Neither the honeysuckles nor the witch hazels require support, but they are the better for the shelter of the wall, on which may be also grown the gold and silver ivies, Hedera argentea variegata and H. angularis aurea. In front, in a narrow border, should be planted Daphne Mezereum (the white variety is prettier, but less hardy than the purple crimson type); some small gold and silver hollies (their slow growth will render them suitable for such a situation for many years), and, for the sake of their bright berries, Skimmia japonica and Pernettya mucronata, although it must be borne in mind that to the latter a peaty soil is a necessity. The very early-flowering periwinkle, Vinca Bowles' variety, which has mauve blue flowers and is of less straggling habit than the better known kinds, may form a carpeting under the shrubs, and here, too, the winter aconites, both the type and the new hybrid between Eranthis hyemalis and E. cilicica, E. Tubergenii, should be planted in quantity, as they do best in slight shade. A semi-shaded place protected from cutting winds must be also found for the hellebores, especially for the Christmas rose, H. niger and H. n. angustifolius, which are more fastidious as to their quarters and far less easy to establish than the later-flowering H. orientalis, of which there are very many varieties all worth growing and quite admissible in the winter corner, although the majority do not blossom before February.

Room must be found for that useful if commonplace and (when out of bloom) dull shrub, laurustinus, now known as Viburnum tinus; and, if the soil suits rhododendrons, the earliest flowering of them, the vivid rose R. Nobleanum, should certainly be grown, massed in a bed or in an angle of the walls, if possible. And Prunus Miqueliana is a beautiful little Japanese cherry of dwarf habit which is well entitled to a place in the corner, as it produces its rosy white flowers in November or December and continues to do so until February if in a warm, sheltered place.

Part of the plot should be laid out as a miniature rock garden, in the higher part of which—although the whole should be kept at a comparatively low elevation—should be planted the winter-flowering heaths, Erica carnea, E. mediterranea and E. carnea hybrida, the result of a cross between the two former, which blooms before either of its parents and is of a very rich shade of pink. Other little shrubs suitable for the situation are Berberis buxifolia nana and B. stenophylla nana, Cassinia fulvida (sometimes called the "golden heath," by reason of the colour of its stems and foliage); the dwarf gorse, Ulex nana; Juniperus hibernica compacta—neatest of all evergreens; the creeping juniper, J. prostrata, valuable in winter for the lovely blue-green of its leaves; and another low-growing shrub, Gaultheria procumbens, the partridge berry, the brilliant scarlet berries of which make a welcome patch of colour. In pockets in the rock garden and in little stone-edged beds at the base should be grown the winter-flowering Crocus Imperati; Cyclamen Coum; Iris stylosa (syn. unguicularis), I. reticulata, I. histrio, I. histrioides cicilica and I. alata; the latter, however, is doubtfully hardy in cold districts.

Finally, although we hesitate to suggest the introduction into a garden of that irrepressible rover, Tussilago fragrans, yet its pale heliotrope blossoms are so sweetly scented and appear when flowers are so scarce that, if its roots are confined in a sunk pot, its admission is, perhaps, worth risking. Still, even so restrained, it calls for watching.

These are a few plants that can be planted for winter decoration in the garden, and they will be found useful for brightening many a dull corner. An attempt should be made to cover up any deficiencies that have made themselves apparent now, and secure a winter display next year.

This Week's Work

For Gardens in the South and Midlands.

Start pruning all hardy fruit trees.
Finish planting flowering shrubs, roses and herbaceous plants.
Lift seakale and rhubarb for forcing.
Protect during frosty weather with mats plants in frames.
Take cuttings of perpetual flowering carnations and greenhouse chrysanthemums.
Begin all garden renovations.
Dry off fuchsias and place them under the greenhouse staging.
Bring bulbs in pots into a warm greenhouse for forcing.
Fumigate greenhouse when green and white fly are troublesome.
Lay in manure supplies for winter use.

Royal Horticultural Society's Trials at Wisley.

THE Council of the Royal Horticultural Society is arranging a trial of herbaceous veronicas at Wisley during the coming season, and invites entries of three plants of each variety, which should reach the Director, R.H.S. Gardens, Wisley, Ripley, Surrey, on or before Saturday, December 17th. The necessary entry forms may be obtained o application to the Director.

This Week's Work

For Gardens in Scotland and the North.

Protect Christmas roses with hand lights or frame sashes.
Start retarded clumps of lily of the valley into growth.
Cut down pot chrysanthemums as the plants go out of bloom.
Remove fallen leaves from alpine plants.
Repot or top-dress clivias.
Stir soil between rows of cuttings in frames.
Continue pruning fruit trees and currant bushes.
Make a sowing of dwarf peas for early cropping under glass.
Continue planting rose trees and shrubs.
Double dig site of new herbaceous border.

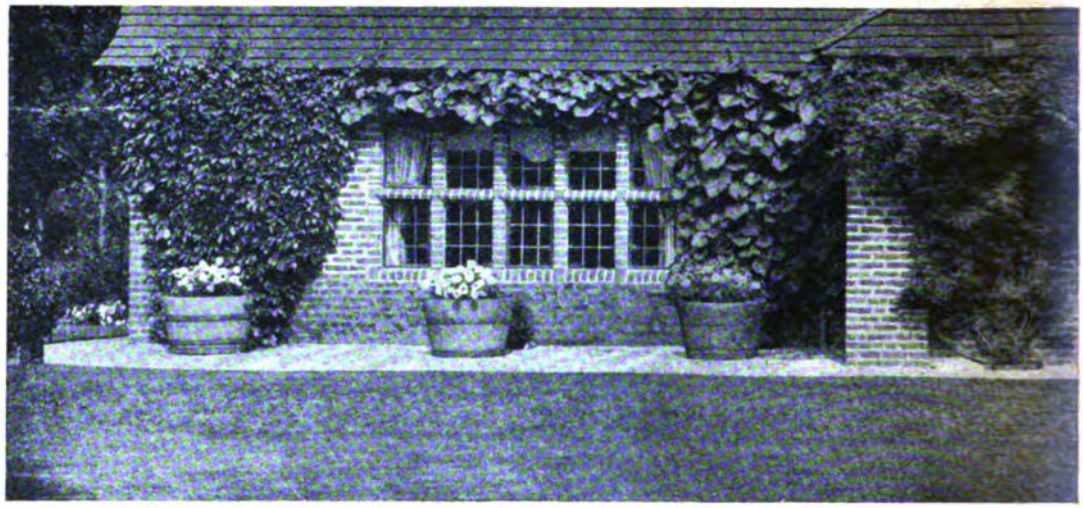
TUBS FOR ORNAMENT IN THE GARDEN

Shrubs, flowers and fruits can be successfully grown in tubs, and these should be placed at different vantage points in the garden to provide the best effects. In front of the house wall at the entrance door, or on terracing or steps, are all admirable positions.



THE POPULAR CHINA ASTERS CAN BE PLANTED IN TUBS WITH GREAT EFFECT. *They will make a bright display throughout the summer.*

FOR this attractive form of gardening it is not necessary to have special tubs made, although very excellent tubs are supplied in teak and oak. Inexpensive and good tubs may be prepared by cutting petroleum casks in half, and butter casks may be treated in the same way. The casks must, of course, be cleansed, and there is a very simple way of doing this. All that is necessary is to burn a handful or two of straw inside the cask. This should remove all future dangers of ill-effects from the oil. If the cask is not easily cleaned by means of burning straw, it should be charred inside with a plumber's lamp. After the cask has been cut in half, two iron handles should be fastened on each tub to render them easy of removal when filled with soil and plants. It is also advisable to place an additional iron hoop round each tub to strengthen it. After this the tub should either be painted green or black ("Adamantine" Garden Black is very serviceable for this purpose), or stained with "Solignum." With occasional coats of paint or stain they will last for many years.

The special square tubs—if tubs can be square—are sometimes used for orange trees, sweet bays and oleanders of large size. These tubs are constructed with movable sides, so that when necessary the roots can be examined and the soil removed. With ordinary tubs, of course, the roots cannot be examined, nor is the soil easily removed without knocking off the hoops and removing the staves, to replace which needs the skill of a cooper. It will be realised, therefore, how necessary it is to have the tubs filled with good soil that is likely to remain sweet and well drained for a long time.

Whatever form of tub is used, proper drainage is essential. This is provided by boring several ½in. holes in the bottoms of the tubs to allow water to pass freely away. The tubs should be raised off the ground by means of tiles, bricks or short legs, and they should be filled with soil in the following way: Over the bottoms put at least 3ins. of broken pots or clinkers; then, on this, some lumpy pieces of turfy loam, grass side downwards; then a layer of rough leaves; and fill up with a compost consisting of two-thirds good rich loam and the remainder of flaky leaf-soil and a suspicion of bone meal. Place the plant in such a position that when "tubbing" is completed there is about 3ins. left at the top for watering and a little surface dressing.

Most plants, from the stately fuchsia to the humble nasturtium, can be made happy in tubs. Perhaps the most popular of all plants for tub gardening is the hydrangea. With very little care and with copious supplies of water in the summer, hydrangeas will give an abundance of bloom for many weeks.

The plants should be transferred from the pots to the tubs in April. The hydrangea, unlike the bay, does not lend itself to any formal method of training, and staking only is required to assist the plants to carry their flower heads or to make them secure from damage by rough winds. The plants should be grown naturally; this will give by far the most pleasant result.

TUB PLANTS MAKE FINE SENTINELS TO A HOUSE ENTRANCE.

FERNS IN TUBS WILL IMPROVE THE SHADY CORNER.

Digitized by Google

No plant can be happier in a tub than the blue African lily, or agapanthus. Its lovely flowers are borne on stout stems thrown well above the graceful dark green leaves. There is nothing so fine for a terrace walk.

The laurustinus and sweet bay are two very popular tub plants; the former flowers well early in the year. Other plants worthy of special mention are fuchsias, camellias, the lemon-scented verbena, and ferns for shady places. This year I am trying cistuses, or rock roses, in tubs. I have never seen them so grown before, but there seems every reason why they should succeed.

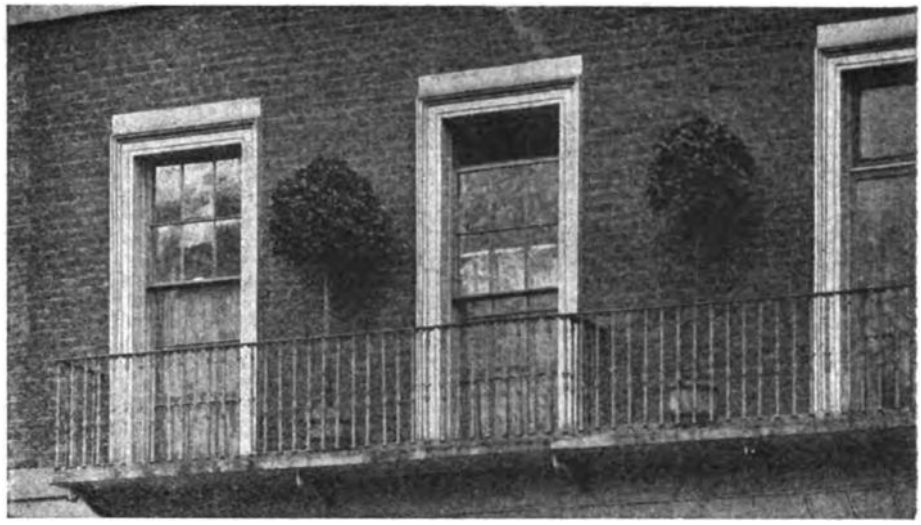
The ivy-leaved geranium is another plant which may be used with good effect in tubs, but it is best to have some fixed method of training the plants. Scented plants are welcome in all gardens, especially if arranged near seats, and as tub plants they can be placed where required. For this reason the lemon-scented verbena, the myrtle, the sweet bay, rosemary, lavender and scented geranium are worthy of a place wherever tub gardening can be carried out.

Then, again, sweet peas, columbines, campanulas and white marguerites may also be grown in tubs. These flowers are all quick growing and give a wealth of bloom in a very short time.

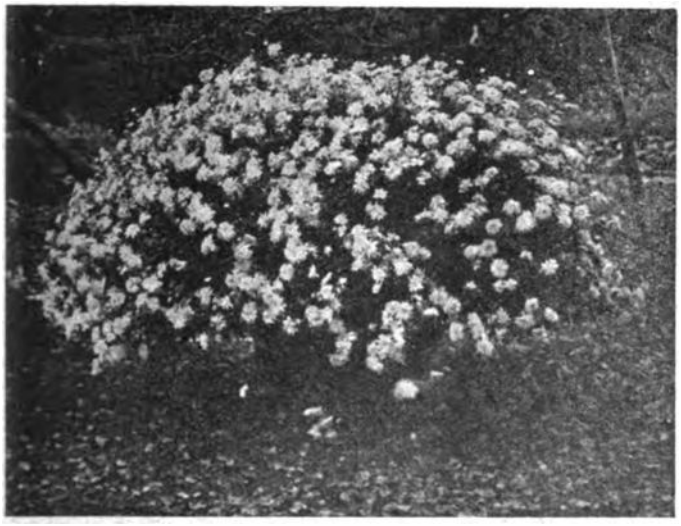
Fruit trees, including apples, cherries and plums, have produced excellent crops in tubs, but top-dressing and feeding with liquid manures is necessary in order to bring the fruits to perfection. Also, strawberries do well in barrels, planted not only in the top, but also in holes about 4ins. square made around the sides of the barrel; but to grow strawberries successfully in this way copious supplies of weak liquid manure are needed.

The most difficult problem in connection with plants in tubs is housing them during the winter. Hydrangeas and agapanthus will take no harm even if several degrees of frost touches them at times, so long as they are dry, and if, when frozen, they are allowed to thaw gradually, but it is usual with these plants to give them some protection during the winter. If they can be placed in a roomy outhouse or similar structure it will be sufficient to carry them through the winter. The same applies to half-hardy plants like the myrtle, pomegranate, oleander and orange, all of which are charming in the summer. I have known these plants to be wintered successfully in cellars, stokeholds and outhouses, but in southern gardens the sweet bay may be wintered in the open successfully. A cool greenhouse is, of course, an ideal place for wintering any tender tub plants. Geraniums are not so easily accommodated as most of the other plants mentioned, as it is not advisable to allow the temperature to fall below 40 degrees. Plants which shed their leaves, or most of their leaves, during the winter, like the fuchsia and the lemon-scented verbena, may be stored in a fairly dark place, but evergreens, such as myrtles, camellias and rhododendrons, should, if possible, find accommodation under a glass roof. The hardiest of the plants may be brought out when the first signs of activity are noticed. They may then be placed outside in a sheltered spot, so that growth may develop gradually, and what pruning is required may, as a rule, be given at that time. Occasional syringings may be necessary, especially on summer evenings, to keep the plants in fresh condition. An important point to bear in mind is that these plants require occasional top dressings with rich soil and goodly supplies of weak liquid manure in the growing season.

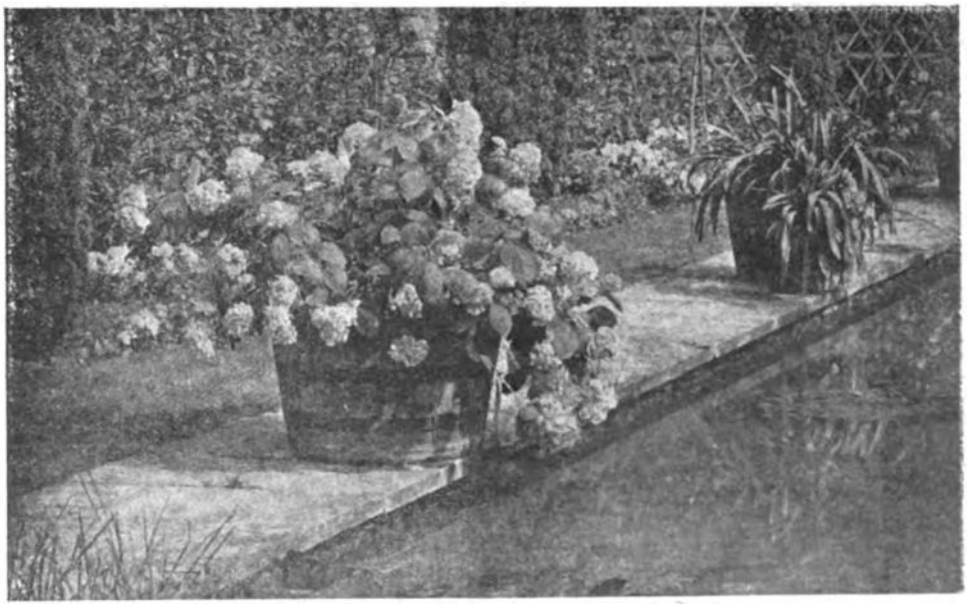
Nowadays conifers are becoming increasingly popular for use in tubs. They look particularly well when placed on terraces or at the top of a flight of steps. If well placed, they will transform many a dull corner. Before planting, place a good drainage layer of broken crocks or cinders at the bottom of the tub, with mossy fibre or well decayed manure on top, filling up with a good loam with coarse sand added. Among the conifers that may be so used are Cupressus, Golden Yew, retinosporas and junipers. With their rather formal yet feathery and graceful habit, they will provide a really attractive feature.—N.



CLIPPED BAY TREES MAKE EXCELLENT TUB PLANTS, AS DO MANY DWARF CONIFERS.
They provide fine decoration in the garden or on a balcony.



A FINE DISPLAY OF CHRYSANTHEMUMS IN A TUB.



TUBS PLANTED WITH AGAPANTHUS AND HYDRANGEAS LOOK WELL AT THE SIDE OF A GARDEN POOL.
Hydrangeas should be allowed to grow naturally. They do not lend themselves to formal training.

ROSES FOR SCOTTISH GARDENS

Failures and Successes This Year. A Novel Planting Scheme.

IN the rose world of to-day, good varieties suitable for general garden cultivation are so numerous that the selection of a small collection becomes a perplexing task. It is customary in a rose article to specify what are described as the best twelve sorts. As applied to horticultural subjects that adjective is so frequently used without regard to its significance or real meaning that its value as an expression of quality has depreciated and is apt to mislead the seeker after knowledge. The reasons are obvious. Roses that succeed in one garden may prove disappointing in another, because they are influenced by soil, situation, climate and methods of culture, all of which conditions are naturally of a very variable character. Then the personal element is a factor that has to be considered. Some rosarians are more successful than others and their superiority in the field of production can be traced to their wider experience or individual aptitude, while the ambition to be ahead of his neighbour or opponents at a local show is sometimes an incentive. At the provincial exhibition of the National Rose Society, held at Glasgow a few years ago, Mr. James Kerr, Stewarton, staged a basket of blooms of Mrs. Henry Bowles, which were the object of general admiration. The flowers were of such a high standard of quality that many amateur and professional growers were induced to cultivate Messrs. Chaplin Bros. pink novelty, but in the interval which has elapsed, nobody has been able to show it to the same perfection, while not a few rosarians have since confessed disappointment at the results obtained under ordinary bedding culture. The best guide is personal experience and in course of time the grower will learn to discard those varieties which, on trial, have proved unsatisfactory and increase his stock of successful sorts. To do so it is necessary to add a few new introductions from time to time, and as a year or two generally elapses before a reasonable price level is reached, he will be in a better position to judge of their individual merits and not rely entirely on catalogue descriptions of raisers or the significance of a gold medal award.

As a large number of roses belong to the nondescript group and new combinations of colour are being created almost every year, the difficulties associated with the formation of a colour classification scheme will be appreciated by readers, and it may better serve the purposes of this article to discuss those varieties which, on the basis of experience, observation and report, have done well during the past season.

Taking the red or crimson roses first, Etoile de Holland, General McArthur and Earl Haig, have justified their good reputation. In several parts of the country the latter sort is described as the best red rose of the autumn, and among others which have excelled in a poor season, may be mentioned Fred. J. Harrison, Hugh Dickson, Covent Garden (especially in September), Holt Hewitt, Henry Nevard (in the north), and Dr. I. Petyt (in the south-west).

Mabel Morse and Florence Izzard share the leading honours in the yellow group. Mrs. Wemyss Quin was as prolific as ever, and in gardens where Golden Emblem survived, the amateur gained in quality if he lost in the quantity of the blooms. Betty Hulton gave some perfect blooms during the mild spell in early October.

Probably white roses were more affected by the wet season than any other. Frau Karl Druschki seldom developed to the perfect open flower and Marcia Stanhope suffered severe losses. Edel "balled" badly and the outer petals discoloured readily. Strictly speaking Clarice Goodacre is not a pure white, as there is a touch of chrome in the perfectly shaped flowers, but it was the best of the lot.

Pink is a favourite and prolific colour class and embraces many popular varieties that seldom disappoint in a normal season. Mrs. Henry Morse, Caroline Testout, Los Angeles, Mme. Abel Chatenay and the indispensable Betty Uprichard are to be numbered in the catagory of the successful, and a good word may be said of Mrs. E. J. Hudson, although the habit of growth may be considered faulty. Of the newcomers, Dame Edith Helen did not come up to expectation, but Ivy May was most floriferous and took a high place among the decorative bedding roses.

The most outstanding rose of 1927 season in Scotland was undoubtedly Shot Silk. First blooms were a little variable in colour, but autumn emphasised the beauty of the flower, and having regard to its fragrance and behaviour under none too favourable conditions it should be included in every garden collection. Angele Pernet will appeal to all rosarians who appreciate the decorative value of blooms that are carried on strong, erect stems. Admiration also belongs to that class and may be grouped with Mrs. Henry Morse and Ivy May for freedom in flowering. Maud Cuming, pink shaded coral and orange, is a variety that deserves to be more generally grown, while the bushes of Ruth, orange flushed salmon, were seldom without a bloom. Among other roses of the dwarf type which deserve honourable mention are Lady Pirrie (magnificent in late autumn), Venus, Princess Elizabeth of Greece, Mrs. Alfred Tate, Lamia, Lady Inchiquin, Gorgeous, Independence Day, Emma Wright, Diadem, Benédicte Sequin, Dorothy Page Roberts, Mrs. Fred H. Howard and Duchess of Atholl.

In the accompanying plan of a rose garden there are eleven beds in various forms and sizes, which have been designed to meet the requirements of a colour scheme. The four corner beds are furnished with pink varieties, the inner quartette provides accommodation for crimson sorts, while the three circular may either be planted with roses of a yellow shade, or an alternative arrangement of a yellow bed at each end and a white bed in the centre would be equally effective. There is wide scope for individual treatment and selection and a rose garden composed of small beds is generally preferred to larger planted areas, as the former are more easily worked from the paths and offer the grower a larger field of selection. Standard roses planted on the edge of the lawn and ramblers trained on pillars or trellis and carried along as festoons on rope, complete the scheme. Roses are not to be grown, however, to the exclusion of other flowers, and space is accordingly provided in the borders for herbaceous plants, favourite things like sweet peas, dahlias, gladioli, chrysanthemums, etc., while advantage may be taken of the surrounding walls to cultivate a representative collection of hardy fruits.

ROSES THAT MAKE LARGE BUSHES

FLOWERING shrubs are very valuable in gardens where space can be found for them, and there are many gardens where these subjects make a most beautiful display. During the last few years attention has often been directed to the many lovely flowering shrubs that are available for growers who have space for them, and the names of several showy and easily grown hardy species have been recommended by many writers. But in all the articles upon flowering shrubs I have noticed that no reference is made to some of the stronger growing roses that are capable of making large bushes, and one cannot get away from the fact that several of these roses are actually flowering subjects of the highest merit and cannot be excelled by any other shrub. In gardens, therefore, where shrubs are about to be planted, attention is directed to some of the roses mentioned in this article.

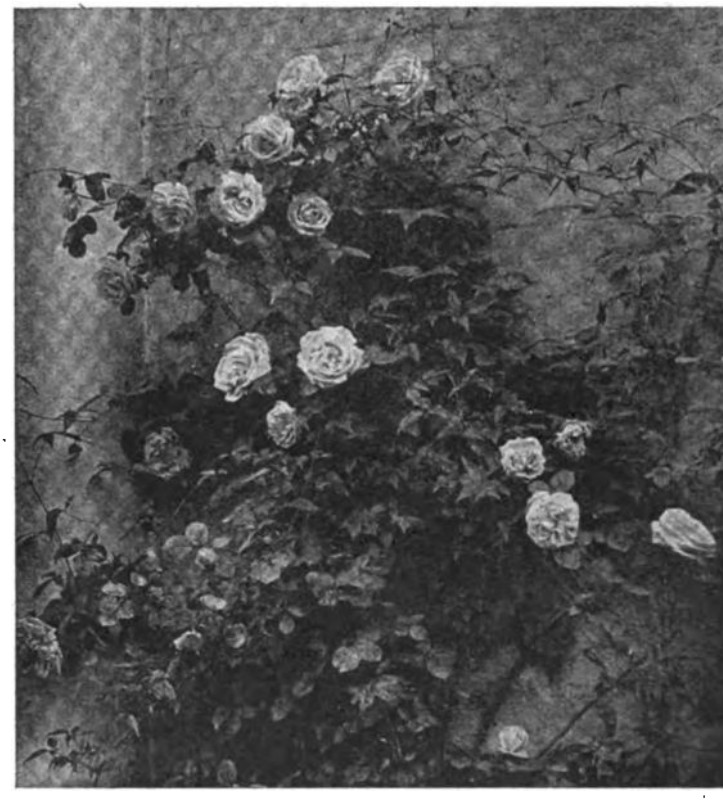
Bush roses have been neglected by raisers of modern times, and there is a good reason for this neglect. It is simply that there was and is no demand for such roses. The call is for roses that are suitable for beds and borders, and a certain height is taken as the standard for them. There are gardens, however, where, apart from beds and borders of accepted patterns, there are also spaces where it has been the practice to fill with shrubs, and no one will deny their ornamental character when judiciously placed. It is into such places that some of the following roses might be used, and they will rival any shrub that one can name. It is true, of course, that they only flower for a very limited period. Their season is, indeed, a short one, but the same may be said of rhododendrons, azaleas, lilacs and others.

To begin with, let us take as an example the old alba roses that still survive. They are rapidly passing out of commerce because nurserymen find that the demand for them is so small. Maiden's Blush is surely one of the most floriferous and sweetest of all shrubs. So, too, is the old Celestial, another of the tribe that is very fragrant. Rosa alba plena, often a sight in old cottage gardens, is surely unrivalled by any other white flowering shrub. These three roses will make bushes 7ft. in height or more, and when in full blossom are most attractive. It is a great pity that they are not more often employed in planting schemes where shrubs are part of the lay-out.

Half a century ago the Bourbon roses were reckoned as the most satisfying of all the garden roses, but with the advent and gradual improvement of the hybrid teas, they gradually dropped out of cultivation. It is a pity. I do not contend that either the Bourbons or the albas compete with our modern hybrid teas. What I do contend, however, is that if we are to plant flowering shrubs in gardens or grounds, we have some desirable things among roses, and these will compare most favourably with anything that can be named for any such purpose. The Bourbons are ideal autumn-flowering subjects, and at that season flowers are somewhat rare upon shrubs. The alba roses, of course, are practically the earliest to come into bloom.

Shakespeare, an old Bourbon variety, is a tremendous grower, and I wonder if it is still in commerce. It made a grand bush, and was a striking sight when covered with its rose-coloured flowers, borne in bunches. Bourbon Queen, deep rose, is another fine old rose. It is a good grower and a constant flowerer. Mme. Isaac Pereire, vivid carmine, flowers more or less throughout the season, but it is especially fine in autumn. Its flowers are somewhat large and lumpy, but they are very sweet. Fragrance is actually a well marked characteristic of the Bourbon roses, and no other shrub can rival them in this respect.

There has been some demand recently for Souvenir de la Malmaison and Mrs. Paul, and I should include both under the Bourbon section. The first, a clear flesh in colour, is a fine autumn rose. Mrs. Paul is a blush white. Both make excellent large bushes.



CONRAD F. MEYER, ONE OF THE MOST OUTSTANDING OF BUSH ROSES.

Yellow flowering bush roses are available in Harrisoni, Austrian Yellow and Le Reve. Harrisoni is more robust than Austrian Yellow and will thrive in places where that sort simply will not. It is very pretty with its double yellow flowers. Austrian Yellow, where it does grow, is quite a sight when in full blossom. It is well worthy of a trial. Le Reve is one of the roses sent out two or three years ago by M. Pernet Ducher, of Lyons. It makes a bush 6ft. in height or more and has golden yellow, semi-double flowers. I have seen some lovely examples of this variety. Mme. Hector Leuilliot, also raised by M. Pernet Ducher, and sent out about 1903, is another yellow rose that makes a big bush. This is a most distinct rose, and it sometimes comes almost the same colour as that of William Allen Richardson. Mention might be made here of another fine bush yellow rose named Reinhard Badeckei. It was sent out by Kordes in, I think, 1918, and I have had it 9ft. high and covered with very large, yellow flowers shaded with red. Frau Karl Druschki is one of its parents, and its flowers are most unshapely and large, but it makes a nice shrub and is quite attractive in a proper place.

George Arends, sent out by Hinner in 1910, was classified as a hybrid perpetual, but I think it really belongs to the hybrid tea section. It is a lovely rose of a beautiful shade of pink, and the shape and perfume are remarkable. It makes a fine bush, notable for its freedom of bloom, and I cannot understand why this rose has practically dropped out of commerce. The reason, I am afraid, is that it was too strong a grower and nurserymen never pushed it. Mme. Wagram, Comtesse du Turenne, an old tea rose, is another fine bush sort. It is a good companion to George Arends. The colour is a pale flesh, and it is remarkably good in autumn. Furstin Pless (Lambert) is descended from Caroline Testout and Conrad F. Meyer. I used to admire this variety very much when I grew it alongside George Arends. It reminds one somewhat of the modern Clarice Goodacre in colour. There is a decided rugosa character about it, but it is well worthy of a place where large bush roses are the concern of the planter.

Coming to the rugosa section we have one or two really good things. The most outstanding from the aspect of this article is probably Conrad F. Meyer. It makes an outstanding bush, and it is one of the first and last to flower. Its flowers, too, are very sweetly perfumed. Its only fault is its enormous spines. It requires staking owing to these, because if left unstaked the swaying of the branches in the wind results in laceration from the large thorns. Despite this little drawback it is well worthy of a place in a collection of the larger growing roses. Nova Zembla, the white form of Conrad F. Meyer, we may pass over, as it is not a free flowerer. It is a sport from C. F. Meyer, but it altogether lacks its free-flowering character. If a white is required there is nothing better than Blanc Double de Coubert, a rose that has been greatly in demand this season. It makes a beautiful bush and has semi-double flowers. Mme. Georges Bruant is another fine white rugosa with semi-double, fragrant flowers. Amelia Graveraux has deep crimson full flowers and it also is capable of forming a nice bush. Rose a Parfum de l'Hay, although not quite so vigorous as the other rugosas I have mentioned, is well worthy of notice. It is one of the most fragrant roses in commerce and has well shaped, rich crimson flowers. It is a rose which deserves wider popularity than it enjoys at present and it should appeal to everyone who likes scented flowers.

There are two moss roses which make good bushes. The old purple moss, the nearest colour to blue we have in roses, is a very vigorous grower, and I have seen plants 10ft. in height. The other variety is Cumberland Belle, with silvery rose flowers. They are both typical moss sorts.

THE BUSY MAN'S PAGE

December Reminders.

GET as much planting in the fruit garden as is possible done before Christmas, as the coming of the New Year always brings a lot of fresh work.

Attend to pruning, digging, nailing and clearing up generally.

Wash the trunks of fruit trees with a winter wash if this seems needed.

Prunings from gooseberry bushes should be burned in case they hold the spores of the American gooseberry mildew.

With gooseberries and currants it is a very good plan to syringe the bushes with a mixture of lime and soot in solution to keep away the birds.

In the vegetable garden wheel manure on to vacant land and trench it 2ft. deep. Leave the ground in a rough state until the spring, especially if it is of a retentive nature. In all cases the more fully vacant land can be exposed to the action of frost the better.

Use the hoe in dry spells among growing crops of cabbage, broccoli, brussels sprouts.

Any vegetables or salads grown in frames should be given the greatest possible amount of air in mild weather.

Outdoor lettuces may need some shelter with dry fern, etc., if the weather is severe.

Forcing operations with such plants as asparagus, seakale and rhubarb are now in full swing, and with a little scheming a succession can be maintained. Where a hot-bed is available it is interesting to start a few potatoes, which will provide some very welcome dishes in the early part of the coming year.

There is not much to be done in the flower garden beyond generally tidying up and mulching with decayed manure.

Lawns should be swept and rolled occasionally when not in too wet a state. A dressing of guano or some other artificial manure will be very helpful. About 4ozs. to the square yard should be scattered in mild rainy weather.

Deciduous ornamental shrubs that flower in the summer and autumn should be pruned by cutting now the older wood and shortening back the leading young shoots. Almonds, peaches, lilacs, winter jasmines, forsythias, etc., which flower in the spring and summer, should not be pruned now but after flowering.

Bedding plants in the cold frame should be kept from actual frost, and water should be given very sparingly.

Cinerarias and calceolarias will not need artificial heat if they can be kept frost-free. Primulas and pelargoniums require a little warmth if they are to be brought into full flower. Fuchsias can be rested off and placed under the staging, where they can be allowed to become almost dry.

In the greenhouse ventilation should be given whenever the weather permits, and only on foggy days, or when there is a keen frost, should the house be kept closed.

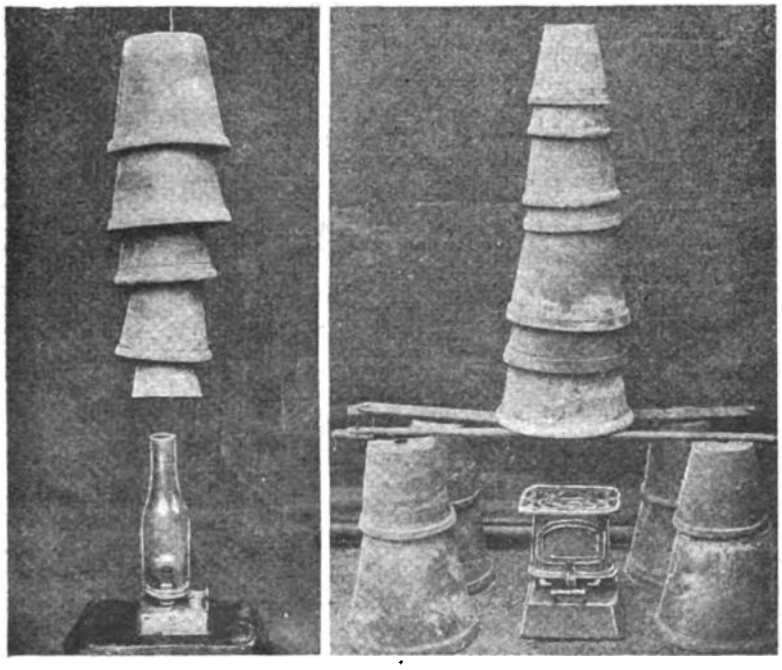
Well rooted bulbs do not require a great deal of heat to bring them into flower, and in fact, in many cases, strong forcing is harmful. It is a good plan to use water that is just off the chill and overhead sprinklings are helpful. Arrange the starting of the batches so that a good show will be available for Christmas.

Keeping Frost Away.

THERE are a good many more or less tender plants which can be wintered quite well in a cold greenhouse or a conservatory providing anything like severe frost can be kept at bay. At any time now a sharp night may come along, and it is well to be prepared for the emergency. Without any artificial heat at all much may be done to keep the frost from the plants by means of sheets of newspaper. These should be placed lightly over the plants, care being taken to cover all parts of the foliage. It is worth bearing in mind that during the winter delicate plants are much less likely to suffer from cold if they are kept on the dry side. Active growth is largely suspended, and anything like a really wet soil is sure to be harmful.

If the conditions are very winterly it is worth while placing a paraffin lamp in the house. See that the wick is well trimmed and the burner quite clean; also before shutting up for the night adjust the flame so that it is not likely to go up and smoke. The heat from such a lamp secures a better distribution if things are fixed up in this way. Stand the lamp on the floor and then on either side place bricks or boxes. These should be arranged so that the base of a large inverted flower-pot can be rested on them and so over the chimney of the lamp. To the large pot add two or three more of smaller sizes, and when the pile is complete a considerable radiating surface for the heat will have been secured. Another very effective way of heating a small greenhouse is carried out with the help of a Beatrice type of stove. On the top place a tin biscuit box which is about half-filled with fine sand. When the sand is well heated the flame may be turned to a point where it will just keep the sand hot. Oil stoves in a greenhouse should always be placed in some corner where they will be out of the draught, seeing that if the flame gets blown about it is almost sure to smoke. If liked, the plants may be grouped round the lamp, as, providing the burner is quite clean, such fumes as are given out are not harmful.

At times, even with the utmost care, pot plants do get nipped with frost, and they then present a very dejected appearance. Nine times out of ten the specimen is not really dead, although people who do not understand matters will often kill a frosted plant by giving it warm water. This tends to thaw the cell contents too quickly, with fatal results as far as the plant is concerned. A safe method is to give the soil a good soaking with water at the ordinary temperature. At the same time sprinkle the foliage with cold water and, finally, place the plant in a cool place where there is no frost. In a few hours the plant will have revived most wonderfully and be little the worse for its experience. When the soil has been soaked in this way it is most important that the plant should not again be exposed to frost.



A NOVEL METHOD OF HEATING A SMALL GREENHOUSE WITH OIL STOVES.

How to Grow Fine Mignonette.

An Annual that Requires Careful Treatment.

FEW plants are more valued than mignonette, and yet it is curious that quite often it is grown in a very indifferent manner. This is a pity, for there is no plant which pays so handsomely for careful treatment. The old idea that one could not transplant mignonette is far from being correct, for, as a matter of fact, the finest specimens are secured by a system which involves removal. Another popular error is that mignonette revels in very rich soil, but really the plant cares very little about the nature of the ground in which it grows, always providing there is plenty of lime.

The finest bed of mignonette which was noted last season was growing in a limestone district on land which had not been enriched in any way at all. Moreover, from start to finish the bed had never been watered. Therefore, on stiff, close soils it is far better to work in mortar rubbish, or anything similar, and to use no other fertiliser. This will result in finer plants which produce highly fragrant blossoms with great freedom. In the ordinary way the seed may be sown in March. After the plants have developed a little, thin out rather drastically, as crowded mignonette never does well. If some specially fine plants are needed, this is the way to get to work: Sow a tiny pinch of seed in 3in. pots about the end of March. Then remove all save one of the plants and, at the end of April, place out of doors. Prepare the holes in the ground in advance, and get the entire ball of soil from the pot so as to avoid root disturbance.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Room Plants in Winter.

DURING the summer months, when doors and windows are frequently open, indoor plants generally thrive well. As soon as fires are commenced, however, there are generally a number of casualties among the ferns and plants that are grown in living rooms. It should not be forgotten that plants dislike sudden changes of temperature just as we do, and, further, that in a warm temperature they consume more moisture than in the extreme cold. A fire in the room tends to exhaust the moisture in the soil very rapidly, and watering may require to be done more frequently. The water given should be slightly warmed, *i.e.*, to make it as warm as the temperature of the room, otherwise the plant receives a shock.

With plants that are "resting," *i.e.* ceasing to make new growth for a time, it is advisable to keep them away from heated rooms. If a greenhouse is not available, a spare box-room or shed, provided it is frost-proof, will often prove a better place in which to winter pot plants than a room which gets heated during the day and is allowed to cool rapidly during the night. But always remember that the cooler they are kept, the less water they require. A word about bulbs in bowls and pots. Very hardy bulbs like snowdrops and crocuses *must be grown in a cool atmosphere* all the time. Hyacinths, daffodils and tulips can be brought on more quickly by growing them in a warm room. Of course, all bulbs grown under the artificial conditions need keeping cool, in the dark, and well ventilated for a few weeks after planting.

The Best Form of Lime.

LIME in some form must be applied to the garden each year to maintain the correct soil condition. After a season of much rain and consequent excessive growth, the addition of lime to the soil is specially important. There is no better form of lime to apply to the garden than freshly slaked quicklime. It is obviously cheaper to buy quicklime, because slaked lime contains 40 per cent. water. Air-slaked lime is inferior to that of properly water-slaked. No more water should be used than will thoroughly wet the lumps of quicklime. Heat is produced and in twenty minutes a very fine dry powder will be obtained. Avoid using an excess of water, or a sloppy mess will be formed. It is advisable to wear old clothes when liming the garden.

Alternative forms of lime are available. Many of the limestone quarries grind the actual *limestone* without burning it at all, and this is quite as effective, only a more liberal dressing should be applied. *Ground limestone* is calcium carbonate, and *slaked quicklime* is calcium hydroxide, which eventually turns into the carbonate. *Chalk* is another form of calcium carbonate, and powdered chalk should be applied at double the quantity of ordinary lime.

Another substance which contains lime is the *acetylene waste*. But if this substance is used, it should be exposed to the atmosphere for a month before application. *Lime rubble* is a mixture of sand and calcium carbonate, and is excellent, especially for heavy soils, to which it can be applied in liberal quantities.

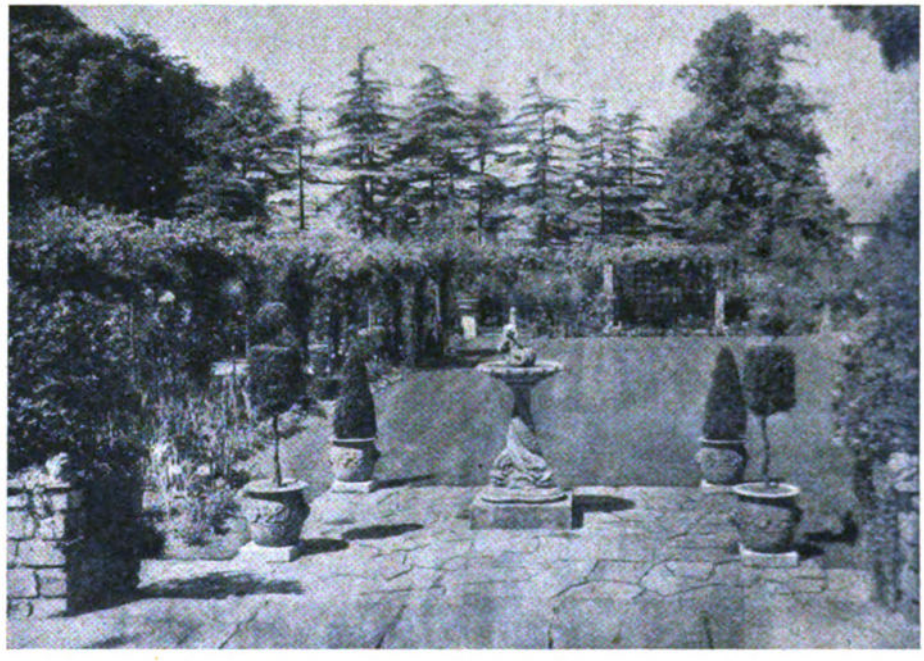
Quantities to Apply.

Apply as follows: Slaked quicklime, 2 oz. to a square yard; ground limestone, 4 oz. to the square yard; chalk (powdered), 4 oz. to the square yard; acetylene waste, 2 oz. to the square yard; and lime rubble, 6 oz to 8 oz. per square yard. These quantities are not too much to apply annually to gardens in smoky districts, but all gardens would benefit from a dressing of lime in the above proportions every two years.

The Value of a Background.

WHERE space permits, a row of conifers like the Cedrus deodara in the illustration forms an admirable setting for a garden. There is a feeling sometimes that in planting trees one is planting for posterity, but the trees in the illustration are comparatively young. After all, we have to thank many gardeners in the past for the beauties of our countryside to-day, and if, in a sense, we are planting for posterity when we plant trees it is pleasant to reflect that we leave the world a little better than we found it.

In the illustration, four box plants are grown in ornamental pots. The two in the foreground are clipped in conventional designs. An alternative would be to use dwarf conifers which give congested bushes, of formal appearance, without the necessity for clipping.



A WELL DESIGNED SUBURBAN GARDEN SHOWING THE VALUE OF A WIDE SWEEP OF LAWN AND A WELL FURNISHED PERGOLA WITH A BACKGROUND OF TREES.

Replanning an Old Garden.

THIS is the time to consider the replanning of the whole garden, so that next season any mistakes in design which have become apparent this year, may be corrected. It is opportune, too, for those who take over an old, neglected garden, to clean it up, preparatory to reconstruction work, which will be done during the winter as occasions arise.

Suppose, for instance, that you have a typical town garden, with a weedy lawn in the centre, an even weedier path round the lawn, surrounded on all sides by borders in which leggy shrubs and frowsy Michaelmas daisies run riot. It takes only a season or two of neglect to transform the best of gardens into such an untidy patch. The first thing to do is to cut back the shrubs. If they are very overgrown, you can hardly trim them back without making them unsightly for a time, but most ordinary shrubs will very quickly shoot again into healthy bushes. It may be that flowers on some kinds will be scarce next season if the pruning is very severe, but the shrubs will be all the better in the years that follow.

The next thing is to cut the grass of the lawn. If the lawn is to remain, see that the surface is fairly level. If hollows or humps are present, lift the turf carefully, level the subsoil, and replace the turf. Give a dressing of lawn fertiliser, and remove large weeds. Roll it occasionally during the winter, and by next spring it should be ready for use, and able to be kept in condition by a weekly cutting and rolling. Of course, if rain stands in puddles on the surface, or if much moss is present, it may be necessary to lift the turf in places and arrange bricks or clinkers a foot below the surface, to improve the drainage.

Now turn over the gravel paths with a fork, or put down fresh gravel if this is necessary. Cut all the tops off the dying herbaceous plants in the borders, and put them with fallen leaves and other vegetable refuse into a compost pit, sprinkling each layer with a little lime and a little soil. The contents of this pit will be used during the winter as digging is done, and will add far more value to the soil than if the rubbish were burnt and only the ashes used.

At this stage, the reconstruction of the garden must be considered. If a rockery, a water garden, or other special feature is to be introduced, this must be fitted into the most suitable part of the rock garden.

Finally, do not forget, in replanning the garden, that a simple design is best for small areas. Try to make each feature seem a necessary part of the garden. An archway should be over a path, and all paths should lead somewhere. Contrive that some pleasing feature is seen from the house windows, or from the entrance to the garden. A sundial or garden ornament seen through an archway adds apparent size to the garden. A rose screen or a few rose pillars give privacy to any part where this is desired. These features can be all constructed during the autumn, so that the garden will be in readiness for the spring planting.

NOTES ON THE FLOWER GARDEN

A Standard Hydrangea.

Hydrangea paniculata Grandiflora.

A DIFFERENT method of growth can almost transform a plant beyond recognition. Certainly few gardeners will have seen Hydrangea paniculata grandiflora, the plumed hydrangea, grown as a standard, familiar as they may be with the ordinary type of border shrub or the pot-grown plant.

In Japan it grows as a forest tree, and as n that country winter is severe, it can survive our climate better than may be supposed.

The illustration is of a fine tree grown in the garden of Mrs. Medlycott Rumsey, Dormer Cottage, Camberley. It is now more than twenty years old, and from year to year is covered with large bold blossoms nearly a foot long and 4ins. to 6ins. through.

In cultivation its requirements are few; for preference, it enjoys a site sheltered on the north and east, and a well drained situation. For fine flower display, mulch the ground in early spring and prune back the last year's growth severely in February or early March. This encourages the large panicles of creamy white blossom to form at the terminal of each shoot and keeps the round, dome-shaped tree in form.

In point of flowering period there are few shrubs that remain in blossom so long. Commencing to flower at the end of July, it tints gradually to rose colour and finally russet, until leaf and blossom fall with the first frosts.

It should certainly be grown in the standard form more commonly, and used as a specimen shrub, not included as an ordinary member of the shrubbery, where it would not be seen to advantage, and would be likely to lose its shape from overcrowding.—M. B.

Violas for the Small Garden.

IT is questionable whether any other garden flower gives a better display of colour over a long period than the viola. There is, of course, a great difference between the varieties, and it is not always wise for the novice to purchase varieties seen at exhibitions, for often the plants which produce large blooms are not suitable for border culture. The essential things for a border plant are a good tufted habit, with a quantity of blooms to each plant, and a vigorous constitution which will stand the weather.

Violas will grow in almost any soil, but the condition of the natural soil should be improved by deep digging and by certain additions according to the nature of the soil. On sandy soil, or soil of a peaty kind, cow manure is the ideal manure to use. Heavy soils should be dressed with lime, and all available strawy litter, bonfire ashes and very well rotted horse manure should be added. Wireworms and leather jackets are enemies of the viola, and if the land in which they are to be grown is infested with these pests, a good dressing of a soil fumigant is useful at this season of the year.

Late Autumn and Winter Cuttings.

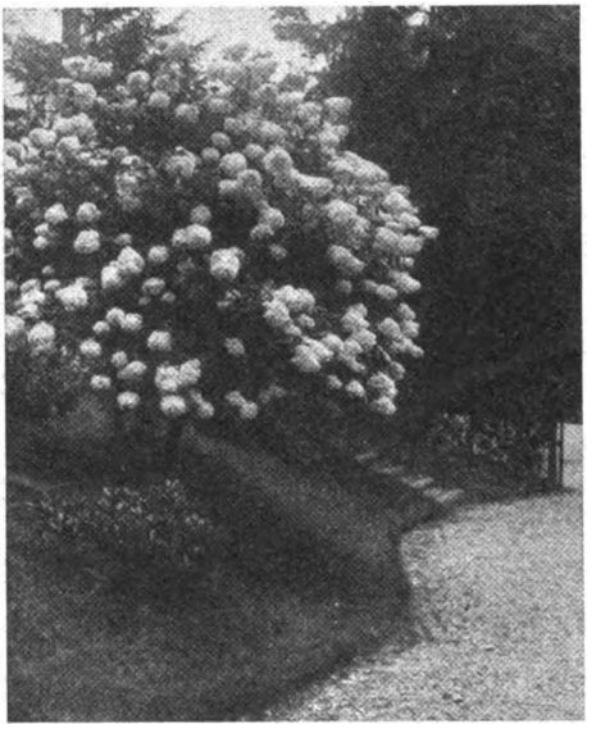
One good authority on viola culture states that he finds plants raised from cuttings taken in November, and wintered in cold frames, are almost invariably the best and most vigorous plants during the following summer. Even in December cuttings can still be taken with excellent results. Cuttings should be sturdy and short jointed. Take them from the base of the crown of the old plant, about 2½ins. in length, and insert in a cold frame in rows 3ins. apart, allowing 2ins. between each plant. The soil in the cold frame should be well mixed with sharp sand. Good cuttings cannot be made from hollow-stemmed pieces, and in each case the lower leaves on the stem should be removed before the cutting is inserted.

Where no cold frame is available, cuttings will usually root in the open, but it may be more reliable if small pieces are broken away from the base of the plants with tiny rootlets attached. This can usually be done quite satisfactorily.

Ventilation Essential.

One of the most important factors in the care of the viola in cold frames during the winter is the giving of sufficient ventilation. The plants are very hardy, and except during the most severe of frosts some air should always be given, otherwise damping off will account for many fatalities among the stock of cuttings and mildew may appear.

It is difficult to advise regarding varieties on account of the variations in tastes, but the following may be regarded as good plants for the garden border: Swan (white), Primrose Dame (light yellow), Mrs. E. A. Cade (deep yellow and very early in blooming), Archie Grant (purple), Maggie Mott (mauve), W. H. Woodgate (almost blue).



HYDRANGEA PANICULATA GRANDIFLORA AS A STANDARD MAKES A DECORATIVE SHRUB FOR A FRONT GARDEN.

A Distinctive Magnolia.

Magnolia conspicua.

THIS, the yulan or lily tree, is one of our best early-flowering shrubs. The rather low rounded trees or shrubs are about 8ft. high and about the same distance across, but I believe this tree is capable of attaining a height of 30ft. or even 40ft. It is deciduous, but the flower buds are conspicuous throughout the winter months, when, with the arrival of congenial weather in the spring, they develop into pure white fleshy blooms 6ins. or 8ins. across when fully developed. When partially open the flowers are erect and bear some resemblance to a lily, and in this stage the tree is even more beautiful than when the blossoms are flat. Nevertheless, it is a beautiful tree, quite hardy, and will thrive in most gardens. It is a native of China, from whence it was introduced in 1789, and no doubt there are now some fine examples in various parts of the country.

Propagation is effected by grafting on M. Soulangiana, and at one time M. conspicua was largely employed for forcing work. For the cool greenhouse it will be found useful, coming into flower fairly early without much fire heat.—B.

A Brilliant Blue Rock Plant.

Gentiana acaulis.

OF late years much has been written concerning the merits of recent additions to this charming genus, so much so that the merits of the above or the gentianella are apt to be overlooked. During the month of April this charming plant produces quantities of its beautiful blue tubular flowers, and no plant in the garden can excel it for sheer beauty and attractiveness at this season. It can be grown at the very front of an ordinary border: in fact, I have seen it as an edging with excellent results; while a bay in the rock garden filled with this handsome species is sure to afford pleasure, especially if the visitor meets with it unexpectedly. In such a position we have it at Castleford, Chepstow, and the best colony is one that was lifted, divided and re-planted in September. It is a native of the Alps and Pyrenees, and it is quite hardy in this country. In some gardens it will thrive and flower freely, while in others no amount of care will induce it to succeed. In spite of this, everyone with a garden should give it trial and try it in various positions and different soils before giving up the attempt. As a general rule a south-east or south-westerly aspect should be chosen, and the rooting medium consists of loam to which is added a liberal quantity of lime or mortar rubble and sand. The gentianella forms a dense carpet of short growths, and when overcrowding begins the plants should be lifted, divided and re-planted a few inches apart. Firm and deep planting is essential, and later on, when the shoots are well advanced—say the following early spring—a top-dressing of leaf-mould, loam and sand will be beneficial. This mixture is worked well between the growths, made firm by treading, and when the operation is completed the tips of the shoots will be just visible above the soil. It is also a good plan to place stone chippings over the soil, and should the weather prove dry during the spring and summer the roots must be kept well supplied with water. There are different forms of G. acaulis, including a white variety, but few are improvements on the type.—T. W. B.

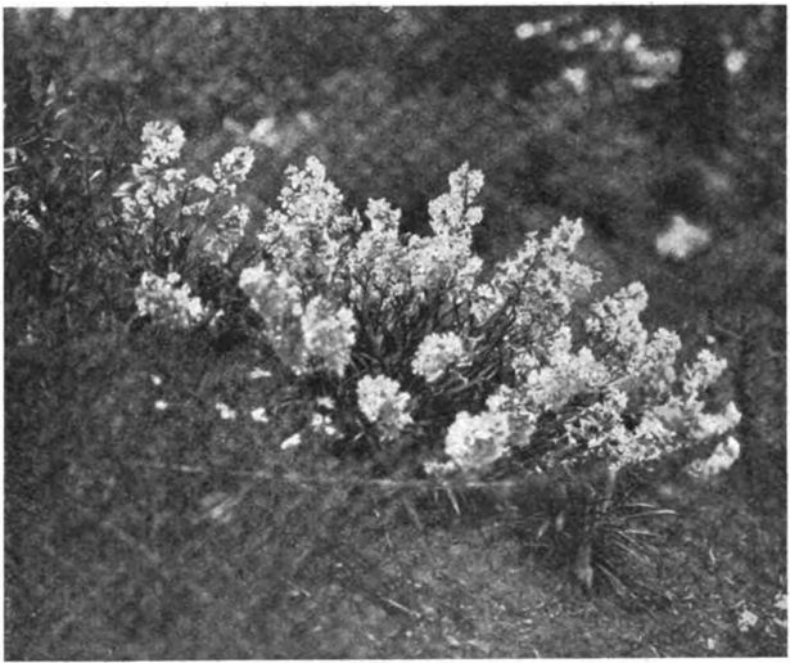
The Lychnis in the Border.

THE most popular member of the lychnis family for growing in the border is undoubtedly L. chalcedonicum (sometimes known as the Maltese—or Jerusalem—cross flower by reason of the arrangement of its petals), and a bold mass of its pure scarlet flowers has certainly a gorgeous effect, especially when seen against the background of a yew hedge, or one of the blue-grey Cupressus Triumph of Boskoop, or some brown-foliaged tree such as the copper beech or Prunus Pissardi. Like the majority of its kin, L. chalcedonicum prefers a dry, light soil;

Digitized by Google

but in a very hot and rainless season it should be well supplied with water, or its leaves will turn brown half-way up the stems in a disfiguring manner. There is a white variety which is not particularly desirable, but the double scarlet is worth growing, although it is, perhaps, scarcely an improvement on the single type; and there is also a comparatively new pink variety, L. c. Salmonea, which has its attractions; it must, however, be kept well apart from the scarlets, or the result will be horribly discordant. Lychnis fulgens, with bright red flowers, is a front row plant, as it is only 1ft. high, against the 2½ft. of L. chalcedonicum. L. Haageana, a hybrid between L. fulgens and L. coronaria, is also dwarf and red; but the colours of the newer L. Arkwrightii, said to be the result of a further cross between L. Haageana and L. chalcedonicum, range from salmon to crimson scarlet, and it is 1½ft. in height. This is a most effective border plant, but it is considerably less robust than L. chalcedonicum, and some growers find it safest to treat both it and L. fulgens as half-hardy annuals. These hybrids are rather weak in the stem and need careful support.

The Rose Campion, Lychnis (otherwise Agrostemma) coronaria, is perfectly hardy, and its rich velvety crimson flowers and silver grey leaves are very charming. The white variety is not particularly interesting; but the hybrids, L. c. Walkerii, atrosanguinea and œli-rosæ, although seldom seen, are worth growing. The native lychnis divica is only suitable for the wild garden; but its double varieties, both white and crimson, are quite good enough to be permitted in the border; and the same may be said of the double form of the indigenous Ragged Robin, L. flos-cuculi fl. pl. The best known variety of this is a bright rosy pink; but there is a paler one, and also a white. These pretty flowers, which grow about 1½ft. high, bloom in June and July, and are admirable for cutting. Lychnis flos-govis, of much the same height, has a rather longer flowering season, and its colour may be fairly described, I think, as a light shade of crimson. It seeds itself freely. Both L. flos-cuculi and L. flos-govis are good near the front of the border; but L. viscaria splendens fl. pl., the fine rosy crimson flowers of which rise on 1ft. stems from neat tufts of foliage, is a better plant for the actual edging, on account of its compact habit. It blooms from the end of May until mid-July.—R. E. H.



THE DOUBLE FLOWERED FORM OF LYCHNIS VISCARIA WITH ITS ROSY BLOSSOMS AND NEAT TUFTED HABIT MAKES A FINE EDGING PLANT.

A Good Winter-Flowering Shrub.

Viburnum Carlesii.

IN V. Carlesii we have one of the choicest introductions of recent years, and it is a plant that should be represented by one or more specimens in every garden, even if it is planted in the ordinary or herbaceous border. Since that date it has gradually but surely found favour among all shrub lovers, and a noteworthy fact concerning this exquisite plant is, it does not require a vast amount of space to develop in, thus being most suitable for gardens of small dimensions. V. Carlesii, probably the best of the viburnum family, makes a shapely bush 3ft. to 4ft. high, and the flowers are produced in terminal clusters during the months of April and May. The buds open a pale flesh pink and gradually become white as the blooms develop; these are deliciously fragrant, and reminiscent of the best of the daphnes. At first this shrub seems rather slow in growth, but once established it makes headway, and proves to be a free-flowering plant. It appears to be perfectly hardy, and is quite at home in a variety of positions. Most of the plants are grafted on the wild or common viburnum, and for this reason the base of the plant must be watched for sucker growths. These often appear during the first season or two, and must be cut out directly they are seen, otherwise the real plant will be destroyed.

V. Carlesii gives the finest results in a well drained soil such as can be found in most gardens, and where the soil is of a heavy clayey nature a liberal dressing of loam and leaf mould would be an advantage.—B.

VIBURNUM CARLESII IN FULL FLOWER IN FEBRUARY IN THE ROCK GARDEN.

A NEW PRIMULA, P. REDOLENS, SIMILAR IN HABIT TO P. FORRESTII BUT WITH PALE PINK FLOWERS WITH A YELLOW EYE.

A New Primula.

Primula redolens.

THIS species was discovered by the writer as long ago as 1911, in the gorge of the Mekong, due west of Likiang, in the province of Yunnan, China. Apparently it has never been collected since. The writer found a clump of the plant in fruit, growing on the dry cliffs, and sent seed to England. No dried specimen was collected, and the species is not represented in the herbaria of Kew or Edinburgh, unless in the latter by a cultivated plant. P. redolens is now fairly well known in big gardens. It is one of the perennial "Suffruticosa" species, ultimately forming a tangled clump of thick woody stems, bearded with the remains of old leaves, from the ends of which spring the current year's leaves, in rosettes, and the flowering stems. The Suffruticosa primulas fall into two groups—those with very short stems, the flowers nestling among the leaves (*e. g.*, P. pulvinata, P. Dubernardiana), and those with long stems which, like P. redolens and P. Forrestii, hoist the flowers well above the foliage.

The two last-named are somewhat similar in appearance, except in colour. P. redolens has flowers of a pale purplish pink or lilac pink, fading to blush cream, with yellow eye. Both leaves and flowers are fragrant, the whole plant being covered with downy glandular hairs which impart a slightly sticky feeling. The leaves are stalked and the stalk is expanded at the base, the margin is irregularly toothed, and the upper surface is slightly rough, showing deep veining. The flowers, either twelve or more, are carried in a compact head on stems 6–9ins. high. It is an exceedingly decorative plant when well grown, with its pale pink blossoms.

Like all members of the section, P. redolens likes a bright sunny position and gritty soil with sharp drainage. Most of the species require lime, and are best grown on limestone rocks. At Bodnant (Lady Aberconway's garden), where the photograph was taken, P. redolens is also flourishing out of doors on a rock wall facing west.—F. K. W.

WHY NOT GROW MORE PEARS?

A Selection of Some of the Best Sorts, with Hints on Planting and Treatment.

PEARS are not planted in the small garden to anything like the extent that apples are, and it is probably safe to say that in comparatively few gardens where they are grown do the trees behave in an entirely satisfactory manner. Possibly the complaint is that the trees grow rankly and show scarcely a blossom. Perhaps they flower freely enough but never "set" fruit, or the fruit that does "set" never "finishes" nicely; or the complaint may be that nearly every fruit is disfigured by the scab disease. Disappointments such as these seem fairly general—much more general than they should be!

It is certain that pears have pronounced "likes" and "dislikes" regarding soil and situation, and the planter setting out to grow good dessert fruit must proceed with due caution, for except in certain favoured districts pears seem the least accommodating of all hardy fruits. On the other hand, when the gardener is able to give the trees a suitable site and a soil they like, and is prepared to take pains over all cultural attentions, splendid crops of delicious pears are the rule rather than otherwise.

By some knowledgeable gardeners a warm wall or fence—facing south or west—is considered more or less essential for the growing of regular crops of well matured dessert pears. Without a doubt such shelter is a distinct advantage, greatly assisting, as it does, fruitfulness and improving the quality of the crop in a marked degree. In Northern and Midland gardens something of the sort may well be indispensable, though there is no shortage of good varieties, which, planted in the open, will ripen heavy crops of first-class pears in most reasonably sheltered gardens—especially in the warmer counties.

The fact that the trees may be easily draped with netting and protected from frost and cold winds during the blossoming period is a most telling point in favour of growing pears against the house wall or garden fence. In some gardens the blossom on trees in the open is spoiled year after year, so that the gardener despairs of ever getting good crops. In localities where this sort of thing is experienced wall trees are invaluable.

In the espalier and cordon forms of training —especially the latter—pears do remarkably well, and from these trees the finest pears will be gathered. The smallest space will take one or two of the single cordon type of tree, which trees, by the way, are best planted obliquely—at an angle of 45°—inclining preferably to the south. For the open garden pyramid and bush-shaped trees are the best choice, the big out-of-reach standards being suitable for the roomy orchard only.

When espaliers or cordons are being ordered from the nursery it is well to stress the point that trees on the dwarfing quince stock are required, the Angers quince being as suitable as any and better than most. This applies to compact bushes and pyramids also. Trees on the pear stock invariably grow rankly and are slow in coming into bearing, giving colour to the old adage that "he who plants pears, plants for his heirs," a saying which does not apply to trees on the quince stock.

For the guidance of the planter it may be mentioned that a warm, deep loam approaches the ideal for pears, and while it is a mistake to make the ground rich with manure at planting-time, unless established trees are "done" well, the quality of the fruit will suffer. If the garden soil is heavy or waterlogged, or, to go to the other extreme, if it is shallow and a mere sand, then some special preparation for the trees had best be made—certainly where trained trees are to go in. A liberal addition of turfy loam to the existing soil may suffice in the average garden, but in extreme cases the old soil should be removed to a depth of from 2ft. to 3ft. and (after laying drains, if required) replaced with an importation of fresh loam, with which is mixed mortar rubble, wood ashes and compost from the potting shed, etc. Also basic slag dug into the ground at the rate of about half a pound to the square yard cannot fail to better conditions.

Firm planting is essential whatever the nature of the ground, and the very common mistake of planting too deeply must be avoided. The depth to set the tree may often be gauged by the old soil mark on the stem, which shows the depth to plant now. But with trees on the quince stock see they are placed with the union of stock and scion just below the soil surface when planting is finished. As a rule, something like 4ins. of soil over the roots is ample.

There are numbers of good varieties, some much more "difficult" than others. This list includes just a few of the best all-round sorts likely to prove satisfactory in the average small garden:

Doyenne d'Été.—Small, yellow, with red flush; in season in July.

Laxton's Superb.—Large, yellow; August.

THE LARGE HANDSOME FRUITS OF DOYENNE DU COMICE, A PEAR OF UNEQUALLED FLAVOUR.

Souvenir de Congres.—Very large, with red cheek; September.

Dr. Jules Guyot.—Large, yellow, with red cheek; September.

Louise Bonne of Jersey.—Yellow, with a red flush; October.

Beurre Hardy.—Large, russety; October.

Conference.—*The* amateur's pear; long-necked, brownish russet; October-November.

Durondeau.—Large, long, russety; October-November.

Doyenne du Comice.—Of unequalled flavour; large, yellow; November.

Fondante de Thirriott.—Large, yellow with red flush; November-December.

Josephine de Malines.—The best "keeper"; small, yellow; January-May.

It seems seldom realised that most dessert pears cook splendidly if gathered hard, though if pears specially for stewing are required, then Bellisime d'Hiver (keeping until March) and Catillac (until April) are a good choice.

When selecting varieties to plant, it should be remembered that each variety is fit for eating over a very short season—some for a week or so only—and that several varieties must be grown to obtain a succession of dessert fruit. Rarely is a large quantity of dessert fruit required at one time—rather a few pears weekly—and to put in several trees of one sort often leads to waste. This is another argument in favour of cordon trees, which take up very little room and permit a number of varieties to be grown in a comparatively small space.

And the question of pollination must not be overlooked. Most pears are more or less self-sterile and crop disappointingly if facilities for cross-pollination are lacking. It is unwise in the extreme to plant a solitary pear in the garden—unless a close-by neighbour grows several sorts—and equally wrong is it to plant two or three trees of one variety only. Put in two or three varieties. The different sorts mostly flower at much about the same time as one another and any two or three are likely to go well together.

The pruning of pear trees once they are formed and shaped is almost a rule-of-thumb matter. Side shoots or laterals should all be cut back to two or three buds, and the leader or extension shoot at the end of each branch shortened by half or one-third, according to the vigour of the branch, the weaker the growth the harder should the leader be cut.

A mistake commonly made and one responsible for many disappointing trees of the type which, in spite of an abundance of blossom, rarely carry much fruit, lies in allowing the spurs along the branches to become too long and gnarled. If these spurs are cut back at the winter pruning to two or three plump buds, and the most crowded along the branch cut away to leave them a minimum distance of, say, 6ins. apart, almost certainly there will be much better fruit-setting and finer fruit altogether.

Fairly hard pruning—and regular pruning—is a means of checking the scab disease (which causes pears to "spot" and crack), since much diseased wood is removed; but in addition affected trees should be sprayed with Bordeaux mixture immediately before and shortly after blossoming in spring.

Finally, note that pears, especially the wall trees on quince stock, need to be well nourished. A mulch of decayed manure round each tree in late spring or early summer is extremely helpful, and this should be followed with liberal waterings with dilute liquid manure as the fruit increases in size.

FOR SCOTTISH GARDENS

Notes Practical and Critical for Amateurs, by a Scottish Expert.

REPORTS regarding the germination results of autumn-sown sweet peas are particularly good this season and indicate a high percentage in different parts of the country. At the close of my lecture at Mosspark the other night, a member of the audience related, with a pardonable degree of pride, that every one of his seeds had germinated; and later on, at Ayr Chrysanthemum Show, Mr. Currie of Barskimming Gardens, Mauchline, mentioned that he had obtained a 95 per cent. germination. Considering that the harvesting of the sweet pea seed in England was distinctly unfavourable this year, the testimony of these growers comes as a pleasant surprise, and it will be interesting to learn how other gardeners have fared.

Now that the rose trees are in process of defoliation, the leaves that have fallen from the plants should be gathered up and burned, especially when the foliage has given evidence of the presence of mildew or black spot. Although they are not visible to the naked eye, the resting spores of mildew and the eggs of the green fly may be wintering on the bushes, and it is much easier to encompass their destruction when the plants are in a dormant state than in summer, when they are clothed with foliage and flower. Bordeaux mixture, which can be safely used as a winter wash, is an effective agency if applied now, and again in February, but some growers prefer the following formula, recommended by the late Mr. Spencer Pickering as a combined fungicide and insecticide: Copper carbonate 1½oz., ammonia 16 liquid oz., and water to make up 10 gallons. After diluting the ammonia with 12 pints of water, add the copper carbonate, and when the latter substance is dissolved, make up the required quantity with water. While there is no certain known cure for black spot, this treatment of winter spraying promotes cleanliness, which is the chief factor in the prevention of disease.

The maintenance of colour for the decoration of the small greenhouse in late autumn and early winter is sometimes a puzzling problem to the amateur. Chrysanthemums, of course, are indispensable, as they are capable of providing bloom until Christmas, when the first of the daffodils, hyacinths and crocuses come into flower; but variety has its attractions and most gardeners endeavour to allocate their limited accommodation to meet the requirements of these favourite subjects in their respective seasons. To keep a greenhouse or conservatory gay during the dull days of autumn and early winter there are no more useful plants than the scarlet salvias, which, with good treatment, provide a brilliant display extending over a period of two or three months. All the varieties are easily propagated by seeds or cuttings. Plants raised from seed in February come into flower in summer, and to ensure a display in autumn the early blooms may require to be pinched in their young state. To produce stocks from cuttings cut back the old plants after flowering and keep them in a cold house or frame until spring, when they can be started into growth in the greenhouse with the object of encouraging the growth of young shoots. When these are 2ins. or 3ins. long the best should be selected and rooted in a sandy soil under moist conditions. As soon as the seedlings can be handled, transfer them to 3in. pots, and once they are established their subsequent culture involves no more attention than that usually given to chrysanthemums, provided they are never allowed to flag for want of moisture. Any of the splendens varieties lend themselves to greenhouse treatment, but Scarlet Queen is mostly favoured by reason of its tall spikes of scarlet flowers. Its popularity, however, is being challenged by a newer introduction named Harbinger, which at the time of writing is at the height of its bloom. The plants are of a dwarfer and more compact habit, and the darker foliage forms an effective setting to the vivid hue of the flowers, which are produced in profusion.

Those varieties of mid-season chrysanthemums which have finished flowering under glass may now have the foliage cut back and the pots placed in a frame or cool greenhouse to provide cuttings, by which method of propagation it is intended to provide a new stock of plants for next year's blooms. Choice varieties, such as Jean Pattison, Almirante, Dolores, La Pactale, Sanctity and the white and yellow Thorpe's and other favourite examples of the double type should all be perpetuated by that simple process, and those gardeners who are fortunate in possessing plants of the newer singles, of which Absolute, Phyllis Cooper, Susan, Raleigh and Mrs. Godfrey are typical, would be well advised to take all the cuttings they can obtain from these decorative sorts of the front rank. December is a good time to take cuttings of indoor chrysanthemums, but the work may be continued until the middle of January. Use a sandy compost in which to root the cuttings and afford protection in frosty weather.

Although the frost has gone for the time being, the weather is still unsuitable for outdoor operations in the garden. The wind has been from the east for about a week, and, as dry days are few and far between, the soil is too sodden to encourage the planting of roses, fruit trees or shrubs. Arrears of work are, consequently, accumulating, and if these are to be overtaken before the days are at their shortest, advantage must be taken to push on with the planting of any new specimens that have been received from the nursery, on every favourable opportunity. Many things are possible in the south which, if followed in our more severe climate, would be courting disaster, and for that reason it is safer to postpone the planting of roses and herbaceous subjects which cannot be overtaken before the end of the year until spring. Under the variable weather conditions that are characteristic of December the garden frame will require close attention, particularly in wet weather, as damping-off is the cause of losses among seedlings and young plants raised from cuttings. The admission of air is, therefore, essential, and this may be regulated by opening the sashes a little at the top and raising the lower end by propping it up with a piece of wood and by removing the lights completely on mild sunny days.

ST. MUNGO.

HINTS WORTH REMEMBERING

Half a guinea will be paid each week for the most useful or interesting hint sent in by a reader. Five shillings will be paid for all others published. Payment for these hints, which should not exceed 150 words in length, is made on the 7th of each month following publication. Responsibility for the accuracy of these hints must rest with the Contributors.

THE HALF GUINEA HINT.

Two Good Flower Effects.

I saw two uses of flowers in a west country town lately which I thought were well worth imitation.

The first was a nasturtium wall. The garden of a small house was bounded on one side by an unsightly bare wall quite 12ft. high. It had been wired all over and planted with nasturtiums, alternately scarlet and cream. The plants had covered the entire surface of the wall up to the coping. They were flowering in such profusion that they formed a dazzling mass which, when lighted up by the sunshine, almost defied description. There was an invariable exclamation of astonishment and admiration from passers-by on the road when they came suddenly within sight of its glory. As the nasturtium has a long flowering season it will be some time before the beauty of that wall is over.

The second was a clematis porch. It belonged to a large old house dating back to far away centuries and was built of grey stone. Clematis in four different colours had been planted on each side of the porch. The red, white, pale lavender and vivid purple had been allowed to mix freely. They were all in full blossom and the effect of the mixed colours against the cool grey background of the old house was charming.—H. G.

Seakale.

At this season of the year most gardeners will be attending to their seakale beds. One so often sees small heaps of cinder ashes which have not been removed at the proper time, and consequently the seakale has grown into long, straggling and weak crowns which, if left alone, would not produce a good crop next spring. The best method of treating these crowns is to remove all the ashes and cut off the seakale level with the ground, and give a good dressing of salt. Now cover with margarine boxes, size 13ins. by 13ins. by 14ins. deep. The lid having been removed, place bottom uppermost. These boxes may be procured from any stores at about 3d. or 4d. each. Cover the boxes with a liberal supply of leaves, and good seakale will be the result. If the boxes are given a dressing of wood preservative they will last for years.—W. H. F.

To Waterproof Working Boots.

With wet weather comes the danger of garden boots letting in the water. You may, however, prevent this by making and applying the following waterproof mixture: Put some beeswax in a jar, well cover with castor or neatsfoot oil, and stand in a warm place till the wax melts. Then stir the mixture thoroughly and allow it to cool, when it should be of the consistency of dubbin; but if too thick add more oil. To use, warm and apply while soft with a stiff brush. Then warm the boots gently and give a second coat, which will result in their being perfectly waterproof.—S. P.

A Time Saver.

Gardeners being busy people I would like to recommend a home-made screen for sifting soil, ashes, gravel, etc., which I have found effects a great saving of time. Cut some 6in. matchboard (or any piece of board about that width) into two lengths of 6ft. and three of 2ft. 6ins. Nail one short piece square on the end of the two long ones and the two others on the back to strengthen the whole, leaving the bottom end open. Then cover back with strong 1½in. wire netting, nailing a small piece of wood near the top against which to lean a prop when the screen is placed in a slanting position. The material to be sifted can then be shovelled to the top of the screen and, in falling down the netting, will be effectively and quickly dealt with.—E. G. D.

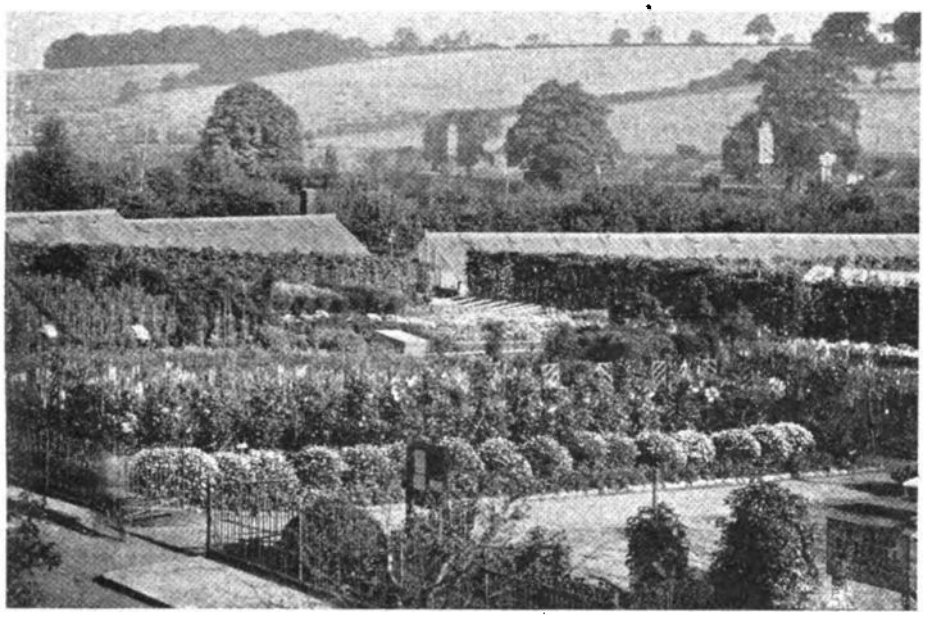
NURSERIES OF THE BRITISH ISLES.—XIII

MESSRS. LANE'S NURSERIES, LIMITED, BERKHAMSTED.

A FEW weeks ago we described under this heading a Scottish nursery firm that had over two hundred years to its credit, and it was mentioned that very few nurseries still in existence under their original name could point to such a long established record of service to the world of horticulture. Our recent visit to Messrs. Lane's, of Berkhamsted, however, has furnished us with yet another link with the past and even a stronger one. This firm had its origin away back late in the eighteenth century, when Henry Lane, the founder of the firm, set out from Uxbridge to establish a nursery business in the Duke of Bedford's country in the Chiltern Hills, which was at that time a famous gardening centre. Indeed, it may be said that that area was the birthplace of modern English horticulture, and not Surrey, as is so often claimed. Evidence points to the fact that gardeners migrated to Surrey to take advantage of the more kindly conditions, both in soil and climate, found in that county, and which, unfortunately, cannot be said of Hertfordshire and Bedfordshire. But that is by the way. The Lanes set up business at Berkhamsted and there they have remained during the last 130 years, gradually building up their business after varying vicissitudes, until it now bids fair to occupy the niche in the horticultural world that it held only some forty years after its establishment. During the early years the firm, under Henry Lane and his son, who later on became head of the business, specialised particularly in vines, roses and fruit trees and shrubs, among other things. Their old catalogues indicate the extent of their stock and the nature of their business at that time, and the old records show that they were considered to be the finest exhibitors of grapes not only in this country, but on the Continent. Their list of awards during last century is extensive and of a high standard, and is a record of which any firm might well be proud. In 1836 and 1837 the firm gained gold and silver medals for their grape exhibits at shows held under the auspices of the Royal Horticultural Society of London, while in later years, at exhibitions in London, Gand and elsewhere, they figured among the chief prize winners for their groups of vines, roses, fruit trees, rhododendrons, etc.

During last century the business passed through three generations, each seeing additions to the ground available for nursery purposes and to the stock of material. In the present century, owing to a number of causes, the firm has not figured so prominently at shows and elsewhere, but there is every sign now that under the able management of Colonel H. V. Lane, the present managing director, who only took over the business two years ago, and who, it may be said, represents the fourth generation, the firm will regain its former high position in British horticultural circles. It is interesting to mention here, also, that it is hoped that Colonel Lane's son will join the firm next year and so bring five generations into the business—a record which we think is unequalled in the annals of British horticulture.

So much for the history of the firm. It is more their present-day activities that concern us here. The real nursery at present consists of some twelve acres, situated in the town of Berkhamsted, where the offices of the firm are also situated. In this section are to be found the various glass houses, where the vines are grown and the extensive propagating frames for raising the stocks of trees, shrubs, conifers, vines, etc. At the time of our visit the majority of the glass houses were filled with chrysanthemums, in which a large cut flower trade is done,



A GENERAL VIEW OF ONE OF THE NURSERIES.

HARDENING OFF VINES READY FOR DESPATCH TO CUSTOMERS.

APPLE, LANE'S PRINCE ALBERT.
One of this firm's introductions.

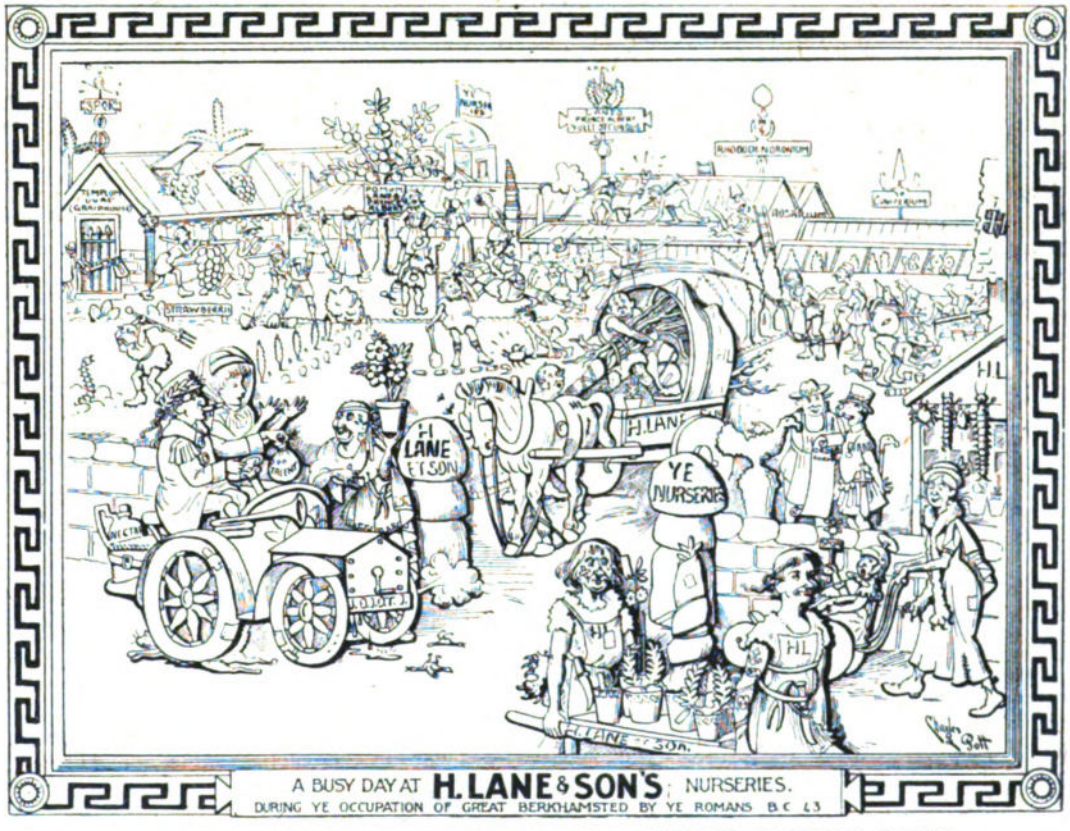
while the frames were occupied by many thousands of cuttings of conifers and different species of shrubs. The work of propagation is carried out in a systematic and methodical way. Full use is made of sand and fibre pits, in which the cuttings are rooted with a fair amount of bottom heat. Thousands of vine "eyes" are inserted annually, and from these a magnificent stock of vines, probably the finest in the country, is reared every year. The illustration of vines in pots shown on the previous page testifies to the high quality of the material sent out from the nursery. The firm is well acquainted with all the little tricks that make for success in the production of really high class vines, and the testimonies received from customers show an appreciation of their efforts. We are, indeed, pleased to note the interest that Messrs. Lane are taking in grape culture, as few firms specialise in this class of work to any extent and the tendency has been during recent years for grape culture to sink into inssignificance. Their stock of vines is large and we have every confidence in recommending those of our readers who have vineries to consult Messrs. Lane as to restocking, etc. In addition to vines, many figs are grown, and interesting experiments in propagation carried out during the last two years have resulted in the rapid increase of stock. Figs, undoubtedly, could be utilised much more freely in the majority of gardens than they are at present. In sheltered situations they are excellent plants for wall decoration and might be more employed for that purpose. Gooseberries, currants and raspberries are grown in this part of the nursery also, and judging by the fine quality of the bushes and canes the situation and soil seem to suit them to perfection. Rarely have we seen such sturdy raspberries and currants. All the leading varieties are represented and the stocks of each is large enough to supply almost any demand. Pot roses are to be found in variety, with a wide selection of herbaceous, bedding and rock plants, together with many varieties of choice flowering shrubs and trees. One of the specialities of the firm is in the growing of standard trees for street and roadside planting purposes. A wide selection of limes, poplars, maples, laburnums, thorns, etc., is offered, and we understand that the firm have entered into many large contracts for the supply of trees for planting along many of the new arterial roads that are at present being constructed.

Another part of the nursery, covering some sixty acres, is to be found at Potten End, known as The Balshaw Nurseries. These are some two miles from the town and are some 550ft. above sea level. This acreage is largely devoted to the cultivation of conifers, forest trees, rhododendrons, azaleas, hardy heaths, roses and shrubs and a variety of fruit crops, including apples, pears, plums, cherries, damsons, peaches, nectarines, etc. A feature of this nursery is the excellent health and quality of the stock, largely due to its situation and skill in cultivation. The crops are fully exposed, and consequently if they come through successfully, as they appear to do, they can be relied upon to do well in the majority of gardens from the standpoint of hardiness. For example, we noted a fine collection of standard roses grown on English briar stock which were in good condition. The reason for their success is probably the fact that the briars themselves grow in the hills around and thus take kindly to nursery conditions. The whole question of hardiness is one that is not sufficiently catered for by many nurserymen. There is little doubt that in this situation really hardy plants are produced. The soil is not over rich and the plants have little or no shelter on the exposed hillside, so that a hardy quality of material which is certain to thrive when transferred to a garden with more congenial surroundings is the result. Amateurs would be well advised to pay attention to this question of hardiness when planning additions to their gardens. It is important to make certain that plants purchased are really hardy —not only where they have come from, but where they are to be grown. It makes a difference to the ultimate success of the plant if it has been raised under somewhat inhospitable conditions in its younger stages.

A fine stock of rhododendrons, mostly hybrids, is carried, while spiræas, deutzias, philadelphus, ribes, olearias, escallonias, etc., are present in variety. In addition to these two nurseries, the firm have recently purchased another fifty acres at the lower end of the town, where next year's roses are already budded and a large quantity of mixed nursery and orchard stock has been planted up. Judging from the growth that has been made since planting, this seems certain to become a valuable piece of ground. All crops seem to thrive in it.

With fruit, the firm's name is well known. Lane's Prince Albert, of which they were the raisers, is still one of the best of our mid-late-season apples. It is interesting to mention another variety that originated a year or so after Prince Albert, but one that never became at all well known, save to those of Messrs. Lane's customers in the district who purchased it at that time. It is known as Lane's Oakland Seedling,



AN ILLUSTRATION REPRINTED FROM AN OLD CATALOGUE OF MESSRS. LANE'S.

The conifers are all of first-rate quality and the variety and stock of ornamental conifers must be one of the largest in the country. A speciality is made of those kinds that are suitable for hedging purposes, and in this connection we would direct readers' attention to the merits of such varieties as Thuja Lobbii and var. aurea, Cupressus Lawsoniana Stewartii, a fine golden coloured form, somewhat resembling Lawsoniana lutea but of a richer colour and with a more graceful habit; Lawsoniana stricta, less erect pyramidal form, with light green foliage; Lawsoniana alba spica, with white tips, and numerous others. We noticed one new variety which bids fair to become a really popular plant and one of which more will be heard about next year, when it is placed on the market. It is to be known by the name of C. Lawsoniana Lanei aurea. It has the habit of Stewartii, being upright, but brighter in colour. It should make a first-rate hedging plant.

and was first exhibited at the Temple Show on May 23rd, 1894, when it received an award of merit. About that time, however, a change took place in the management of the firm and the variety was allowed to sink into obscurity. Its merits have again been discovered. It is a fine late season dessert variety, keeping till May or even June. It is an abundant cropper and has a clean habit of growth. In size it is large, while there is a slight Cox flavour in the fruit.

Space forbids mentioning other activities of the firm. They have an active landscape garden side of the business and they have many fine gardens to their credit, while now they are engaged in developing the sundries side of the business, with great success. Messrs. Lane's is one of the old firms of nurserymen that have remodelled their house to meet the changing conditions of the times and there is every certainty that the changes which have been recently brought about will be more than justified.

THE FRUIT AND KITCHEN GARDEN

Winter Washes for Fruit Trees.

WINTER washing of fruit trees is done for the following reasons: (1) to destroy hibernating insects; (2) to cleanse the trees of mosses, lichens, etc.; (3) to destroy insects' eggs, thus preventing them from hatching and doing damage as caterpillars in the spring.

There are several kinds of winter washes recommended for fruit trees, including: (1) Hot lime wash, (2) Caustic soda, (3) Woburn winter wash, (4) Lime sulphur, (5) Tar-distillate washes.

1.—Hot Lime Wash.

The quantities of material used are: 1cwt. best lime, unslaked; 100 gallons water.

The lime should be slaked, and while still hot water added to make it liquid enough to strain through coarse sacking into the remainder of the water. Stir well and as soon as possible, but the wash should be used within thirty-six to forty-eight hours. The spray should be put on with a power spray and should be done as late as possible, just before the buds are beginning to break. Where power sprays are not available, and where the trees are small, the wash may be applied with a brush, but this is a tedious operation, especially if there are many fruit trees to cover.

One spraying every alternate year should be quite sufficient. This spray has a beneficial effect by burning off lichens and mosses, covering insect eggs so that when the insects hatch out they cannot move and are thus suffocated. It is especially useful against leaf-curling aphis, and to a slight extent apple blossom weevil, while it destroys many other insects which are hibernating or have hatched out early.

2.—Caustic Soda.

The formula for this wash is: 2½lb. caustic soda (98 per cent.), 10 gallons water.

Dissolve the caustic soda in water and the spray is ready for use. It is useful against mussel scale and is an excellent cleanser for lichens and algæ. It has no effect on insect eggs. Apply when the trees are dormant.

3.—Woburn Winter Wash.

Formula: 1½lb. of copper sulphate, ½lb. quick lime, 5 pints paraffin (solar distillate), 2½lb. caustic soda, 9½ gallons water.

Dissolve the copper sulphate in a little water and then put this into a tub containing the quick lime, after slaking, and made up to about 8 gallons with water—and make up to 10 gallons with water. Add the paraffin and stir well, finally adding the caustic soda and again stirring. Apply when the trees are dormant. This wash will destroy lichens, mosses, etc., and will help to control scale insects and also fungus diseases.

4.—Lime Sulphur Wash

Is used against scale insects on gooseberries and apples. It has little cleansing properties and, with the exception of scale insects, upon which it exerts considerable control, it is not much use as a winter wash. Lime sulphur can be bought ready made from manufacturers.

5.—Tar-Distillate Washes.

During recent years there has appeared on the market a number of carbolineum sprays or tar-distillate washes, which have been considerably advertised as winter washes for fruit trees. Carbokrimp, Chafers No. 1, Ialine Tar Oil and Mortegg are a few names attached to these proprietary brands of tar distillate wash. They are of particular use against leaf curling plum aphis, rosy apple aphis, caterpillar eggs, apple sucker eggs, lichens and mosses. The sprays should be applied at a strength of from 6 per cent. to 10 per cent., and sprayed on as late as possible, but not later than ten days before the buds commence to swell, otherwise serious injury may result from the application. One application is sufficient and this should be given not later than the middle of January. It is desirable to use water that is not too hard, as it prevents a stable milky wash being formed readily.—H. D.

Black Currant Bushes.

THE big bud mite—or the gall mite, as it is sometimes called—does a great deal of damage to the black currant bushes in many gardens. In certain soils the trouble seems to be worse than in others. Cutting down bushes to the ground level is not a permanent remedy. The resultant new shoots will be affected at an early date. Where the "big bud" is very bad, both roots and branches of all bushes affected should be burnt. The holes made during the operation of lifting the bushes should be well dressed with quicklime before the soil is levelled. In the meantime, a new plantation should be formed in another part of the garden. The place selected should be in partial shade, for preference, a north aspect border being very suitable. A heavy, retentive soil is better than a light, sandy one; but sound drainage is essential. I prefer surface liming of the soil of the new plantation directly it is dug or trenched to liming later on. Also, the bushes should be dressed with lime sulphur at least once before the spring. If any bushes are only slightly affected, cut out the branches—do not be content with the mere removal of the big buds found. Dress the bushes with lime-sulphur twice before spring.—CHRISTCHURCH.

Strawberries in Pots.

PLANTS well established in pots for forcing should be carefully examined now as the first batch of plants must be placed under glass without undue delay. Hard forcing is not necessary nor desirable. If subjected to a gentle heat the roots begin to grow steadily, and it is necessary for them to do so, or the crown leaves will not be supported by sufficient nourishment when they are developing and the flower trusses. If the pots can be plunged to their rims in a warm bed of leaves for about ten days before they are placed on shelves in the plant house, new roots will grow rapidly. Attend to the drainage and water carefully always.—HANTS.

Parsley During the Winter.

FRESH parsley is always appreciated. Although the plants thrive splendidly in some soils, it will not do so in others. Where the latter is the case, plants that are not growing satisfactorily should be lifted and re-planted in a cold frame or in new soil in a sheltered border near a wall or fence. When this is done the parsley grows freely in many instances, especially if the roots are firmly planted in old potting soil such as that in which chrysanthemums have been grown. Furthermore, it is advisable to protect parsley during very adverse weather; although frost does not kill the roots it destroys the freshness of the leaves. A temporary protection will do much good.—G. G.

Clean the Winter Greens Now.

OUR climate is variable: one week the weather may be mild, the following week frosty, and again, a third week rainy or foggy. Winter vegetables, subjected to such weather conditions, soon lose a lot of their freshness; it may be that many belonging to the savoy and broccoli families decay badly, too.

Alternate spells of frost and fog cause much decay among savoy plants and even Brussels sprouts. Carefully examine all the greens, remove any leaves that are turning yellow, place them in a heap, sprinkle salt on them and, later on, some soil, adding more leaves as they become unfit to remain on the plants. Savoys and very plump Brussels sprouts often split and then decay sets in. If the decaying edges of the leaves are stripped off in good time whole heads may be saved from actual decay. Celery, too, will decay rapidly after a spell of frost. Examine the leaves and stalks at the soil level and cut off—do not pull or twist, as any bruising in this way means rapid decay again after the stalks are frozen—any leaves and stalks found rotting; then sprinkle a small quantity of dust-dry lime on the tops of the plants. Broccoli rarely decays to any great extent. The tops of parsnips should be examined, and blackening leaf-stems twisted off close to the crowns. If left on the crowns of the roots may rot.—K.

New Varieties of Potatoes Worth Growing.

THE best varieties of potatoes for exhibition are not always the heaviest croppers. Those varieties, as a rule, yield but a poor crop, handsome to look at on the exhibition table, but do not always yield a bumper crop, while the varieties that are chiefly grown for culinary purposes are those which produce a large quantity of ware potatoes fit for the table during the greater part of the year. For instance, the amateur gardener would never think of growing Mr. Bresse, Mauve Queen, Edgecot Purple, Crimson Beauty and Cardinal for utility; they are exhibition potatoes, grown to add colour in a collection. The quality is excellent in every case, but the yield is poor in comparison with some of the newer varieties recently introduced. The number of new varieties that now exist is enormous. This is very evident when we consult the seedsmen's catalogues. No vegetable has been hybridised more than the potato. The newer varieties are all more resistant to blight, produce heavy crops and are without exception immune from wart disease.

The following are a few of the recently introduced varieties which are well worth a trial next year. The name in parentheses is that of the raiser.

Claymore (McInnes).—Introduced last spring by Messrs. Croll, Limited, Dundee. A late maincrop variety which produces large tubers, pebble shaped with shallow eyes set very close together. Flesh and skin white. Sprouts pink. Excellent quality when cooked and keeps well in the pit. The plants are strong, upright in growth, with dark green foliage and a profusion of white flowers. Very resistant to blight, which should make this potato an outstanding variety for garden purposes.

Duke of Perth (Young).—Another of the late maincrop varieties producing beautiful oval shaped tubers with shallow eyes. Flesh and skin white; sprouts blue. A strong grower branching freely above ground. Also an enormous cropper and blight resister.

Glasgow Favourite (Sutton and Sons).—This is an early maincrop, but when boxed and sprouted before planting matures as a second early. The tubers are round to oval in shape with very shallow eyes. Flesh and skin white. Excellent quality when cooked crops and keeps well. Will without doubt become a very popular garden variety. It is not a very tall grower.

Incomer (C. Brown).—Introduced last year by Messrs. Dobbie and Co., Edinburgh. A tall, upright grower, strong, robust habit, with white flowers. Broad oval shaped tubers with shallow eyes. The skin and flesh is white. Excellent flavour when cooked.

THE GARDEN

VOL. XCI.—No. 2923. DECEMBER 10, 1927. PRICE TWOPENCE.

GARDENING—A GREAT FORCE

WE are being constantly reminded of the testimony which has been left on record for our edification, that gardening is the purest of human pleasures. With this we are in full accord, but we submit it is even more than this, it is one of the most health-giving and alluring of hobbies.

Its devotees are ubiquitous, and are to be found among men and women in all walks of life. It knows no politics, recognises few limitations, as wherever land is found that can be cultivated, there gardens arise that combine beauty and utility. It has a freemasonry of its own, yet unfettered by stringent laws, and those once initiated in its cult and becoming enamoured of it seldom desert the order, but remain faithful adherents. It is the *open-sesame* to many a conversation, and has relieved the tedium of more than one long railway journey that would otherwise have been monotonous. More than once it has been responsible for a casual acquaintance ripening into personal friendship because of a talk on some particular plant or flower, or the special culture of a vegetable in which both were deeply interested. Indeed, there is scarcely any popular flower which at one time or another has not drawn gardeners together in the common bond of comradeship. One has only to think of the old society of tulip growers in the north of England, the National Rose and Chrysanthemum Societies, as well as that devoted to dahlias, and of recent origin, comparatively, the Sweet Pea and Gladioli Associations. In all these the members of the fraternity foregather to exhibit their best productions and to chat about them. Gardening has become a great force in the lives of not a few, and every year one can see how the influence continues to spread.

And there is really no finality about gardening, as in some other pursuits that could be mentioned. It is ever urging those who have once joined its ranks and have come under its spell to attempt something greater than they have done before; perhaps to strike out on new lines in the raising of fresh varieties of flowers which have long attracted them. There always remains some task to be done. We cannot say, for instance, when we think we have concluded some bit of work to our liking, "There, that is finished and done with!" As a matter of fact, the work of one day is but the prelude to some other duty in the near future which will demand our attention. We can seldom, if ever, write *finis* to our gardening operations. The ground we clear and dig and manure in the winter waits our sowing and planting in spring, and afterwards the hoeing and weeding and tending each particular crop involves, or the plants we grow, need for their full development.

The ideal gardener must ever be looking towards the future in scheming and planning and attempting work that in its season shall bring its own reward. He it is who has been described "ere one flowery season fades and dies designs the blooming wonders of the next." He it is who attends to the wants of his plants and his garden in season and out of season, under leaden skies when work is not always congenial, as well as in summer sunshine. If he cannot, through lack of space or opportunity, grow all he would like to grow, he learns to limit himself and be content with the culture of some definite subjects rather than attempt many with little success. Spasmodic gardening has no place in his thoughts; he believes in thoroughness, and that there is a time for everything; that if plants are worth growing at all, they are worth growing well!

We all know that in the early years of the war how thousands, who had scarcely handled a spade before, responded to the appeal to grow vegetables, and though when the extreme need passed away many gave up what at first they looked upon as a pressing duty it has to be said that thousands have remained loyal to their plots. Not a few of the tyros of those days who knew little or nothing about vegetable culture have by practice and determination to excel become experts, and have exhibited their produce with success. It was only natural when opportunity came that the cultivation of flowers and fruit should claim their attention, and to-day in the growing army of amateur gardeners there are to be found numbers who specialise in one thing or another. If it could be ascertained why it is that gardening continues to be taken up by fresh enthusiasts every year, we should no doubt find out that there is an impelling force which draws and wooes all sorts and conditions of folk, and such a force is contagious. You see it is abundantly demonstrated in new districts where houses are being erected. To-day the garden, as well as the house, counts, and there is a desire to make it beautiful with flowering plants at the earliest opportunity. And the bulk of the work about these new gardens is not "put out," but is undertaken by the occupiers of the dwellings, one of the healthy signs of a personal interest which will continue to grow as the years pass.

This Week's Work

For Gardens in the South and Midlands.

Prune apples and pears.

Spray fruit trees with winter washes.

Take cuttings of perpetual flowering carnations.

Clear up herbaceous borders and lightly fork over the soil.

Protect delphiniums, pyrethrums and kniphofias with sifted ashes.

Carry out all garden renovations.

Clean and prune vines.

Water bedding plants in frames sparingly and protect them during frosty weather.

This Week's Work

For Garden in Scotland and the North.

Plant hybrid lupins in the flower border.

Top-dress lawns and greens.

Plant lilacs for forcing.

Sow cyclamen seed.

Grow gooseberries and currants from cuttings.

Plant suitable trees for screens or wind-breaks.

Fumigate glass houses infested by aphis.

Complete winter planting of rose trees before Christmas.

Continue propagating Japanese chrysanthemums.

Plant laburnum, rowan and double red or pink thorns.

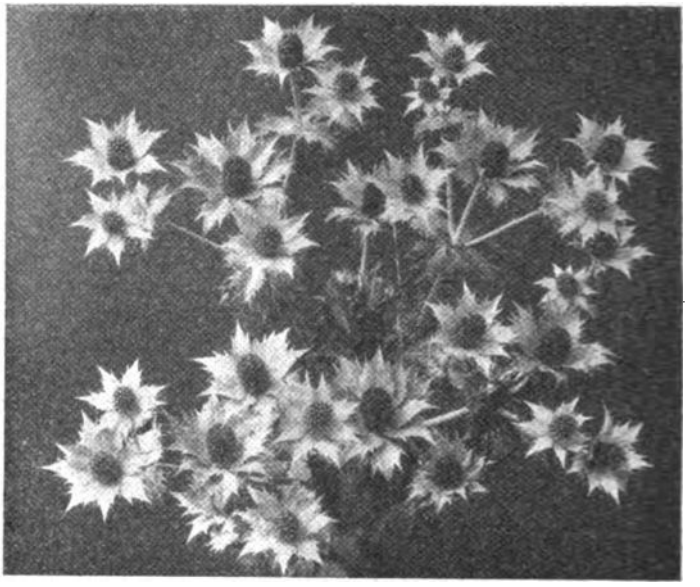
PERENNIAL PLANTS FOR DRY POSITIONS

PERHAPS the most disheartening of all borders is one in a hot, sunny part of the garden, where the soil is probably poor, baked hard in the summer and full of stones and builders' rubble. One often finds such a border at the foot of a house wall facing south, and despairs of ever growing anything satisfactorily under these conditions. It is obvious that the general run of plants will not survive; experiments will prove that the majority of perennial herbaceous plants make puny insignificant growth, and in a year or two fade away altogether. The same thing is true of most of the annuals, though it is true that some, the brilliant orange calendula, for instance, revel under such conditions.

What, then, is the proper treatment for such a border? The obvious answer is to find plants that will stand drought, and use these plants to the exclusion of all other sorts. Before talking about plants, however, it will be well to say a few words about soil preparation. Of course, it is desirable to provide as good a soil as possible, and to this end the ground should be deeply dug and afforded a generous—though not *too* rich—dressing of manure. Even more important in a stony soil is humus, the natural food of plants. This may be provided in the form of rotted leaves, which enrich the soil and at the same time hold moisture for the roots of the plants. Where tall plants are grown, it will be possible to provide a summer mulch of, say, lawn mowings, which will also conserve moisture, though one cannot advise this where small plants are grown, owing to the somewhat unsightly nature of the mulch. A common mistake is to pick out all the stones when digging the border. This is not necessary; the larger ones, of course, may be removed, but stones in themselves hold moisture, and also prevent the soil from becoming caked after copious waterings.

As regards plants to grow, there is no dearth of material; planting may be carried out at the present time, thus ensuring that they shall be well settled in by next summer. Taking the larger plants first, we have Delphinium nudicaule, one of the most striking of the perennial larkspurs. All preconceived notions of this family are upset in this plant, with spikes of clear scarlet blossoms. A deeply dug soil is specially appreciated by this native of California, and it will also respond to an extra dressing of well rotted manure.



THE IVORY THISTLE ERYNGIUM GIGANTEUM IS AN ADMIRABLE PLANT FOR A DRY BORDER.

Among the sea hollies (eryngium) are numbered many attractive plants, all having steely blue flower stems, surmounted by spiked thistle-like blossoms. Some of the most handsome species are alpinum, amethystinum, and giganteum (silver white), one of the finest of all. These flower during the summer months and retain their characteristic iridescent colours over a long period if cut and carefully dried.

It is surprising how neglected are the sun-roses, varieties of our native Helianthemum vulgare. These form low spreading bushes, studded throughout summer with brightly coloured blossoms, which are individually short lived, though produced with reckless prodigality. There are many named sorts to be had, both double and single; *e.g.*, (doubles) roseum multiplex, rose; venustum plenum, crimson; tigrinum plenum, salmon pink; Jubilee, yellow; and album plenum, white; singles are Fireball, red; Yellow Standard; Lemon Queen; oculatum, white; Flambeau, rich rose; and Garibaldi, pink.

Another neglected plant is the Californian fuchsia, Zauschneria californica splendens. Despite a thoroughly alarming name, this plant is of vivid beauty, with long downy leaves, ablaze in autumn with a mass of vivid scarlet trumpet-shaped flowers. Though reputedly of shrubby habit, the shoots usually die down to the ground in autumn, thus affording one a chance of applying to the crown of the plant a winter protection of sharp cinders or light litter.

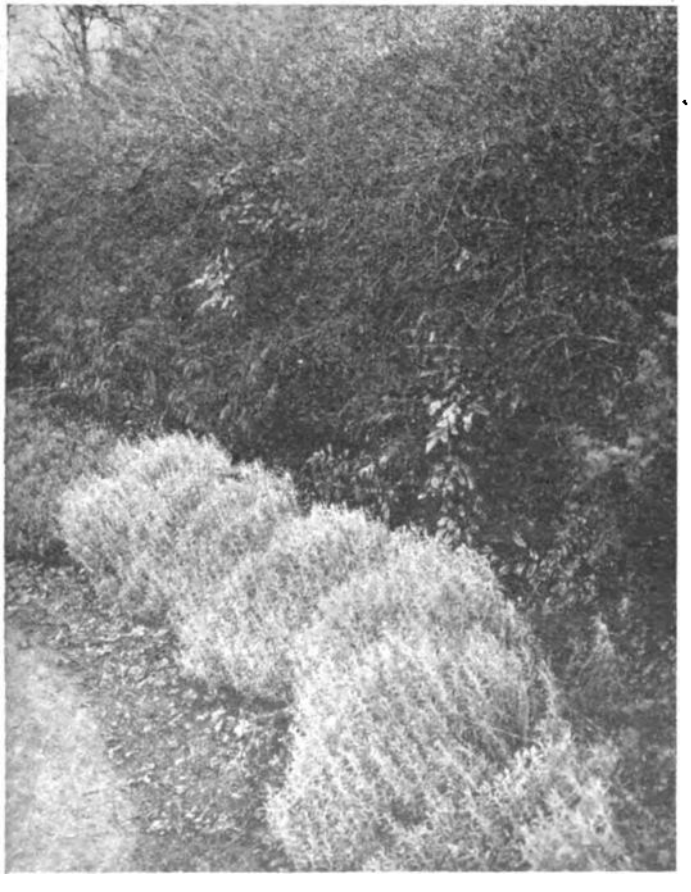
Among the daintiest of all garden flowers are the flaxes, revelling in a dry soil, with which may be admixed a liberal dressing of lime or rubbly mortar. Linum perenne is the commonest form, with a profusion of pale blue flowers throughout the summer months. Finer in every respect, however, is L. narbonense, with larger and richer coloured blossoms, and this should be grown in preference. A white flax is L. p. album, and in L. flavum we have a delightful yellow variety.

A native plant that deserves to be far more widely grown is Malva moschata. This forms a large, bushy plant, each shoot terminating in a cluster of glistening pink mallow flowers. Even more charming is its white variety, M. m. alba, with large clusters of satiny white flowers. It is difficult to understand from whence this plant derived its popular name of "musk mallow" the original species may have been fragrant, but like the modern musk, our garden musk mallow has little or no scent.

Many of the perennial campions will succeed on a dry border, three of the most suitable sorts for the purpose being Lychnis chalcedonica, with compact heads of bright scarlet blossoms during summer; L. viscaria splendens fl. pl., a fine double pink; and alba plena, bearing large double flowers, which are deliciously fragrant.

Though perhaps not particularly showy, the erodiums or heron's bills, are useful, as they flower continuously throughout the summer and have elegantly cut fern-like foliage. The two best for border cultivation are manescavi, purplish red, and macrodenum, pale violet, with darker markings, the latter species being quite dwarf (6ins.).

There is quite a number of evening primroses from which to choose, including some rare and strikingly beautiful sorts. The first of these is Œnothera cæspitosa (or eximia) with large white flowers during July and August. The blossoms are of exquisite fragrance, and produced very freely under favourable conditions. Œ. fruticosa major has deep yellow flowers; while Œ. Wm.



THE SHRUBBY SANTOLINA WITH ITS SILVERY FOLIAGE IS WELL WORTH GROWING AS AN EDGING.

Digitized by Google

Cuthbertson is a semi-double variety of much charm. Œ. speciosa, with light sprays of fragrant satiny-white flowers, is a sort that should not be omitted; two trailing species for the front of the border are Œ. macrocarpa, citron yellow; and Œ. taraxacifolia, bearing huge white flowers, changing to a delicate shade of pink as they age.

A shrubby plant that might be included is the French lavender, Santolina incana, with aromatic silver-grey foliage, and small yellow flowers, though the latter are of little decorative value. This shrub may be kept in bounds by clipping it back to the desired height in spring; the closer it is clipped, the denser becomes the growth, and as a consequence the beauty of the plant is much enhanced.

Having disposed of the taller growing plants, there remains a number of dwarf, creeping species, which are useful for edging purposes, or for planting in a very narrow border. Alyssum saxatile compactum is a popular plant, with hoary grey foliage, and masses of bright yellow flowers during spring. A. saxatile fl. pl., double yellow; and A. s. citrinum, lemon yellow, are two pleasing varieties.

Another popular group of plants, the armerias or thrifts, form compact mats of deep green "grass," with tight heads of pink or white blossoms during summer. A collection of the best sorts would include A. cephalotes rubra, rich red; A. cæspitosa, soft rosy pink, extra fine; A. maritima, silvery pink, and its white variety, A. m. alba.

Almost all the pinks may be grown in the border, including the beautiful border pinks, of which the white Mrs. Sinkins may be taken as a typical example. Of true species, Dianthus deltoides, bright pink; D. fragrans, white; and D. cæsius, pale rose, can be recommended.

Allied to the pinks, Saponaria ocymoides splendens is a showy, creeping plant that will succeed well in a dry border. This plant it smothered in bright pink flowers throughout the summer, and is very close and compact in growth, if shingled over with the garden shears during autumn.

Other dwarf plants are Antennaria hyperborea, rosy pink blossoms and thick woolly foliage; arabis, of which the double white form is the finest; and Cerastium tomentosum, with masses of snow white flowers and pretty silvery foliage.

Another method of treating the dry border is to plant entirely with low-growing shrubs, of which may be specially recommended, lavender, santolina and rosemary. Borders planted thus cause the minimum of trouble, and look neat the whole year round, to say nothing of the fine winter foliage effects of the shrubs suggested. B. D. S.

NEW SWEET PEAS

A Selection of Novelties for Garden Decorations. Seeds can be Purchased Now and Sown in February Next Year.

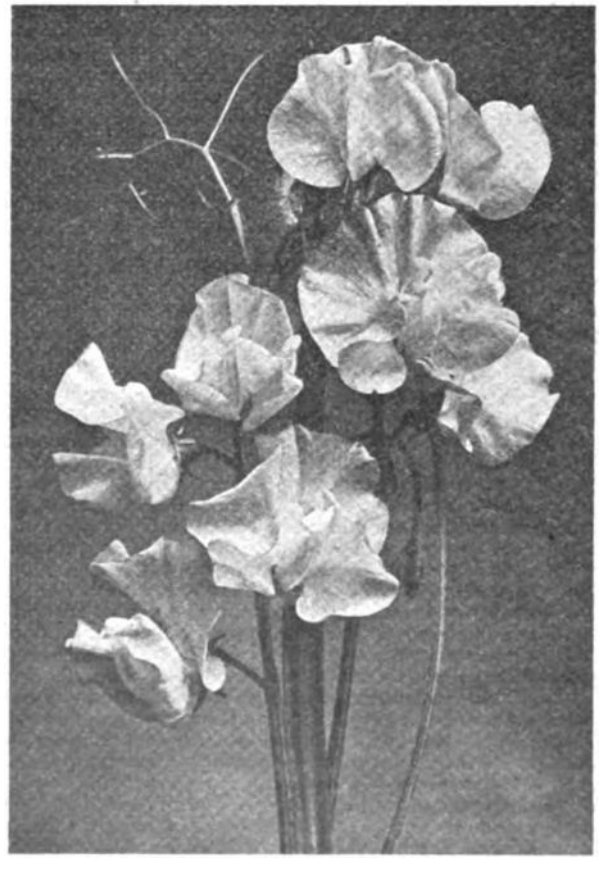
VERY probably greater public interest is taken in new sweet peas than in novelties of any other one flower. The question of cost may be partly responsible, for when one compares their price (usually 1d. or 1½d. per seed) with the cost of a new rose, gladiolus, carnation or dahlia, it is reasonable to surmise that sweet pea novelties are available to a much larger number of growers immediately they are introduced. Even so, initial outlay is not by any means the only reason; demand for novelties is simply an indication of the wonderful popularity of the flower.

Modern sweet peas have reached a high standard of perfection, judging them from the point of view of beauty and general usefulness, and their colour range is very wide indeed; yet we shall undoubtedly obtain more pleasing colour tones as well as many more new shades. Again, there is still ample scope for further improvement in other directions, such as vigour and form. As in every other popular flower, a percentage of novelties fails to become popular and quickly disappear from commerce; some of them may be quite distinct from any other variety, yet they fail to win general approval. On the other hand, among the twenty or thirty new sweet peas which are annually introduced, there are certain to be some which are destined to become popular and to remain favourites until, sooner or later, superseded by better ones.

Here is a list of most of the new sweet peas for 1928, arranged in alphabetical order for convenience. The name of the introducer is given in parenthesis in each instance:

Adorable (Messrs. Atlee Burpee and Co.).—This gives us a new and quite distinct shade in sweet peas. The colour is described by the raisers as a clear salmon cerise on a cream ground, with a suspicion of bronze around the edge of standard and a bronzy-suffused reverse. While neither the flower is as large nor the growth as vigorous as one might wish, the colour is charming and should alone make Adorable one of the most popular of all sweet peas for decorative purposes, both by day and by artificial light. I warmly recommend it as a perfectly distinct and pleasing novelty.

Boy Blue (Thomas Cullen and Sons–Alex. Dickson and Sons).—I saw this pea at the N.S.P.S. 1926 Trials at Twickenham, where it was the winner of the challenge cup for "the Sweet Pea exhibiting the greatest improvement in rich blue colouring until the gentian blue is attained." Nothing is lacking in size of flower, form or habit of growth, and the colour is certainly fine, a deep rich blue somewhat similar to Bluebird. Although I have not had the opportunity of comparing Boy Blue with other mid blues, I believe it will be found an improvement. Really first-class medium blues are few and for colour alone, Sapphire and Heavenly Blue are the best at present, but these have not the size or vigour of the two more popular and better known kinds, Mrs. Tom Jones and Bluebird. One hopes that Boy Blue may combine the best characteristics of the four.



THE BEST NOVELTY IN SWEET PEAS.
The rich cerise pink Mrs. A. Searles.

Brilliant Rose (Atlee Burpee and Co.).—This novelty obtained a certificate of merit at the 1926 Scottish N.S.P.S. Trials. As the name suggests, it is a bright and glowing rose self, distinct from any other variety of its colour. To a large extent, the popularity of this colour-class has diminished as that of the bright cerises and orange cerises has increased, but nevertheless, I feel sure that Brilliant Rose will find many admirers, both among exhibitors and ordinary growers. If it will only retain its brightness when cut, its popularity is assured.

Challenger (R. Bolton and Son).—For a "fancy" coloured variety, this is decidedly pleasing. As exhibited, it appeared to be a cream ground fancy, flushed with a distinct tone of rose, described by the raisers as "a new note of Rose du Barri of a lustrous and lively shade." The broad ivory margin to both standard and wings gives the bunch a very uncommon appearance. The flower is very large indeed, and although I have not seen it growing, I understand nothing is wanting in vigour.

Corona (Thomas Cullen and Son).—This gained a certificate of merit at the 1927 Scottish N.S.P.S. Trials. A very robust-growing pea, with large, perfectly formed flowers placed on long stems. The colour may not be every one's fancy, but for a carmine, Corona is really good and will probably head the carmine colour class. It should make a first-class exhibition variety. The colour is described as richest carmine rose on a glistening, pure white ground.

Dainty Lady (W. J. Unwin).—Of late, Messrs. Unwin have given marked attention to the striped and flaked colour class. They introduced Lady Gay a few years ago, which was a distinct "break" in stripes, and I understand several of their more recent introductions, including three this season, are the result of crosses made with Lady Gay. As the name would suggest, Dainty Lady is a pretty pea, uncommon and pleasing. The ground colour is deep cream, lightly marked and picoteed bright rosy pink. The picotee edge is not the same as one associates with the picotees, Youth, Jean Ireland, etc., but is as well defined as some border carnations. The pink markings do not fade as the flower ages. Dainty Lady makes a very attractive bunch.

Fire King (F. C. Woodcock).—This is a bright orange scarlet, somewhat

Digitized by Google

after the same tone of colouring as the older variety Sensation. The raiser describes it as "a brilliant scarlet flame." While, like other varieties in the orange scarlet colour class, it is not sunproof, yet I understand it stands the sun wonderfully well; but for exhibition purposes one would advise growers to adopt the precaution of light shading.

Fluffy Ruffles (Atlee Burpee and Co.).—This is an American variety to which a very glowing description has been given. It is claimed to be the highest achievement yet attained in sweet peas, a new type, duplexed and frilled, in the raisers' words, "the first of the ruffled sweet peas." Apparently the extra frilly standards of the flowers are duplexed and triplexed to a degree not hitherto found in sweet peas. I must hesitate to pass a definite opinion until I have seen it growing. The colour is rich rose pink, slightly suffused salmon on a cream ground.

Freda (J. Stevenson).—A delicately tinted novelty somewhat after the colouring of Dainty Maid and another 1928 novelty, Greta. The colour is white, lightly tinted pink. It has size and vigour in its favour and should become a favourite with those who admire the delicate tones.

Glorious (J. Stevenson).—Another novelty which gained a certificate of merit at the 1927 Scottish N.S.P.S. Trials. Of recent years, an unusually large proportion of cerise shades has been introduced. For a long time the colour "cerise" in sweet peas had been associated with lack of vigour and smallness of flower; now many of the largest and most vigorous of all varieties are to be found in this colour section. Glorious has the same strong constitution as Charming, while its flowers are slightly larger and the colour is a good deal richer; it appeared to me to be even richer than Coralline. I have no hesitation in warmly recommending this pea as first-class for every purpose.

Greta (A. Ireland and Hitchcock).—Another blush pink on a white ground. It is a strong grower with long stems and large flowers, and gained an award of merit at the 1926 N.S.P.S. Trials.

Happiness (Atlee Burpee and Co.).—A charming shade of coral pink on a cream ground. The wings are slightly deeper than the standard, and there is a light suffusion of salmon to the whole. A very pretty decorative pea which one feels confident will meet with general approval; although it may not be found quite large enough in the flower for keen competition, the colouring is attractive.

Harlequin (W. J. Unwin).—Another of the Unwin stripes (see my remarks under *Dainty Lady*). The colouring immediately attracts attention, whether in the bunch or growing on the plant. It is deep cream, heavily marked and picoteed scarlet on the upper side of wings and back of standards, while the front of standards and under side of wings is almost pure cream, wire-edged scarlet. The whole colour effect is most unusual, yet decidedly attractive, and I recommend it to all who wish to grow something quite out of the ordinary run. In vigour and size of flower, Harlequin is well up to exhibition standard.

Hero (C. C. Morse and Co.).—Awarded a certificate of merit at the Scottish 1927 N.S.P.S. Trials. It is almost too near Glorious in colour for both to find a place in the same collection. The raisers claim that it is an entirely new shade of brilliant, clear cerise. Perhaps one can best convey it as a warmer-toned Daventry. It will be found excellent for exhibition purposes and for all decorative work, particularly under artificial light.

Huntsman (E. W. King and Co.).—A clear, vivid scarlet, perfectly sunproof, which was given an award of merit and reserved for the gold medal at the N.S.P.S. 1927 Trials. As seen growing at the Trials, it appeared to be somewhat similar in shade to that vivid-coloured variety 2 LO, introduced by Messrs. King a year or two ago. Most growers admire the bright, decided colours, particularly if they are sunproof, so that the popularity of Huntsman is already assured.

Jack Hobbs (E. W. King and Co.).—A novelty which excited a good deal of favourable comment as exhibited by the raisers this past season. The flowers are very large, exceptionally broad in the standard, frilly and frequently duplexed, while the colour is a charming shade of salmony shell pink on a cream ground. As seen in the bunch, it is very beautiful and quite distinct from any variety in commerce.

Jessie (R. Bolton and Son).—Received an award of merit at the 1926 N.S.P.S. Trials. On referring to my notes made there, I find that the colour impressed me favourably. It is a perfectly distinct shade of salmony china pink on a cream ground. It struck me, too, that the colouring might fade in bright sunshine, but on this point I may be incorrect. It should be given good culture for exhibition purposes.

Jessie Collingridge (W. J. Unwin).—A clear, warm, bright pink, probably best described as cherry pink. It reminds one somewhat of Messrs. Unwin's older variety, Mrs. Horace Wright; but the colour of this novelty is brighter, while it is a self and not flushed like Mrs. Horace Wright. One would place it as midway between the latter variety and Del Monte. Jessie Collingridge is vigorous, large-flowered and should become popular.

Marjorie Stevenson (J. Stevenson).—A rich, deep carmine of a tone not previously found in sweet peas. Like Corona, it will not appeal to all, but has the undoubted merit of distinctiveness, size and vigour. It will undoubtedly find many admirers.

Mrs. A. Searles (R. Bolton and Son).—In my opinion, Messrs. Bolton would be perfectly correct in describing this as the best novelty of the year. I have heard nothing but praise of it from all who have seen it growing or exhibited. It gained a first-class certificate at the N.S.P.S. 1926 trials, a silver medal at the Scottish N.S.P.S. 1926 Trials and the gold medal at the latter 1927 Trials. The colour, as one would expect, is superb, a rich, salmony cerise pink, lighter and much warmer than Charming and perfectly sunproof. It leaves nothing to be desired as far as vigour, size of flower, length of stem and placement are concerned, and will be found excellent for any purpose. It is equally effective when grown out of doors or under glass, and should not be omitted from any first-class collection of varieties.

Mrs. J. B. Hobbs (E. W. King and Co.).—In habit of growth, size and form of flower, this closely resembles Jack Hobbs, but the colouring is described as soft coral pink; it is lighter in tone than the description, perhaps, conveys. An excellent decorative pea.

C. H. A. S.

(To be continued.)

HOW TO PRUNE APPLES AND PEARS

Established trees should now receive their winter pruning.

THE majority of amateurs who grow fruit trees are apt to neglect the systematic pruning of the trees in summer and winter. Such neglect leads to poor crops. If good shapely trees are desired, bearing abundant crops every year, then pruning, both in the summer and in the winter, must be attended to with every care.

Both the apple and pear produce their fruit buds for the greater part on spurs, though some fruit buds are found as axillary buds on shoots of one year's growth, as terminal buds on short, whippy growths of the same age and as terminal buds on leading shoots. The tendency to produce fruit buds at the tips of whippy growths and as lateral buds on one year's growths is more marked in some varieties than in others, so that a knowledge of the habit of fruiting of a particular variety is very essential to the successful pruning of that variety.

In this article it is assumed that the tree to be pruned has attained its required size and shape and we are only concerned with the pruning of the established tree, for this process varies considerably from the pruning of a young tree, where the development of a well balanced framework for the subsequent bearing of fruit is of primary importance, whereas in the pruning of the established tree we are concerned only with the maintainance of growth and the production of fruiting spurs.

It is as well to point out here that the pruning given in winter will in no way affect the character of the buds present, *i.e.*, change leaf buds into fruit buds or *vice versa*, in the ensuing season. Fruit bud differentiation takes place in summer and therefore at winter pruning we cannot change the character of our bud. Winter pruning regulates the number of fruit buds on a tree, thus preventing overcrowding, acting as a preliminary thinning, enables long spurs to be shortened, and worn out spurs to be removed with the minimum amount of risk to the tree. It is to a large degree restrictive and must be carried out in relation to the differentiation of fruit buds the following summer. Thus, when one states the primary object of winter pruning is the production of fruit buds, one refers to fruit buds which will bear fruit eighteen to twenty-one months hence.

It is necessary to be able to distinguish between fruit buds and leaf buds when pruning. The former are round and plump, while the latter are usually narrow and pointed, with the exception of terminal leaf buds, which are often round, but can be distinguished from fruit buds by being more pointed at the apex, fruit buds being typically blunt.

As a preliminary procedure to all pruning proper, the first operation should be the removal of dead or decayed growths, crossing or rubbing branches and the thinning out of overcrowding growths. The pruning of established trees resolves itself into two classes of treatment (1) the treatment of one year old growths, (2) the treatment of spurs.

One year old growths may be again subdivided into (*a*) leaders, (*b*) lateral growths. Leading growths should be just tipped to cause the buds on the lower portions to break. If weak growing, they may be cut back one half. Laterals required for extension purposes should be treated as leaders. Other laterals should be cut back to two to five buds, according to the variety to induce the formation of spurs subsequently, or if they are very vigorous, removed entirely. Short, whippy growths bearing fruit buds at their tips may be left unpruned.

Spurs, generally speaking, require no pruning, but in the case of a spur which has grown too long, it may be cut back hard, leaving one twig bearing a bud to carry on development. When pruning leaders always cut to a bud pointing in the direction you wish the shoot to develop. Generally speaking, prune spreading varieties to an inside bud, upright growing varieties to an outside bud. The cut should be as near horizontal as possible and not long and slanting.

Apples.—Varieties producing fruit on one year old wood:—Lane's Prince Albert, Early Victoria, Stirling Castle, Grenadier, Gladstone and Worcester Pearmain. Varieties producing fruit at the end of twiggy lateral growths: Worcester Pearmain and Allington Pippin. Lane's Prince Albert and Stirling Castle are examples of trees with a spreading habit;

Digitized by Google

prune to an inside bud. Worcester Pearmain has an upright habit.

Pears.—Vigorous growers: Beurre d'Amanlis, Clapp's Favourite, Marguerite Marillat. Medium growers: Dr. Jules Guyot, Louise Bonne de Jersey, Doyenne du Comice.

Weak growers: Emile d' Heyst, Marie Louise d' Uccle. Most pears will bear a few fruit buds on one year old growths. The fruit buds of the pear are even more readily distinguished by their shape and size than those of the apple. H. D.

PYRETHRUMS for the EARLY SUMMER BORDER

These are Among the Most Decorative of Our Early Summer Border Flowers.

THE pyrethrum is truly worthy of the many praises bestowed upon it, for it is without doubt Queen of the Border during the late spring months. Not only this, but it is also invaluable for cutting, possessing the three greatest merits for this purpose—long life, long stem and wide range of colouring. To these advantages may be added the wonderful grace of the flowers, the singles in particular, and the beautiful "feathering" of the flower-stems.

As regards the plant itself, it is perfectly hardy, a sure "doer," and one that will thrive in almost any soil. It has its preferences, of course, and one would advise, as a counsel of perfection, a rich well drained soil, a sunny, sheltered spot, and abundance of moisture during the summer months. Under these circumstances perfect results should be obtained, so these are the conditions to be aimed at as far as possible. At the same time, in ordinary soils, enriched, of course, with well rotted manure, very fine flowers are obtained, even in a slightly shady position. One thing, however, heavy clay soils are anathema to pyrethrums, and such should be lightened by the addition of vegetable matter, strawy manure, or even coarse cinders or gravel sand.

The question of obtaining stock resolves itself into this: Pyrethrums are easily raised from seed, but out of a large number of seedlings probably very few will prove themselves worthy of retention. On the other hand, named sorts, though comparatively expensive, are true pedigree flowers, and taking into consideration the time and labour spent upon seedlings, it is probably cheaper in the long run to start with named varieties. Pyrethrums are also increased by division of the roots in spring, and, of course, this is the manner by which all choice sorts are propagated. As a matter of fact, it is very desirable that all clumps be divided after three years' growth, even if no increase of stock be desired, for they soon form large stools, and produce such a wealth of blossom that quality is sacrificed for quantity. There is a practice among growers of this plant to cut down the old flower-stems immediately the blossoms have faded, and by feeding and constant watering to encourage a second crop of blossom in the autumn. Whether this is a good plan or no it is hard to say. The secondary crop I consider is rarely of any great decorative value, and also comes when there is a glut of flowers in most gardens, while such feeding must undoubtedly have a detrimental effect on the following season's display. There is one very important point in the cultivation of pyrethrums which I find I have omitted, namely, that of staking. Carelessness in this respect will lead to much disappointment, for the long-stemmed blossoms are sadly bent and draggled by wind or heavy rain, and in this state are more of an eyesore than a decoration in the garden. Three canes should be provided to each clump, bands of raffia tied round these affording the necessary support, and at the same time not destroying the natural grace and beauty of the subject under consideration.

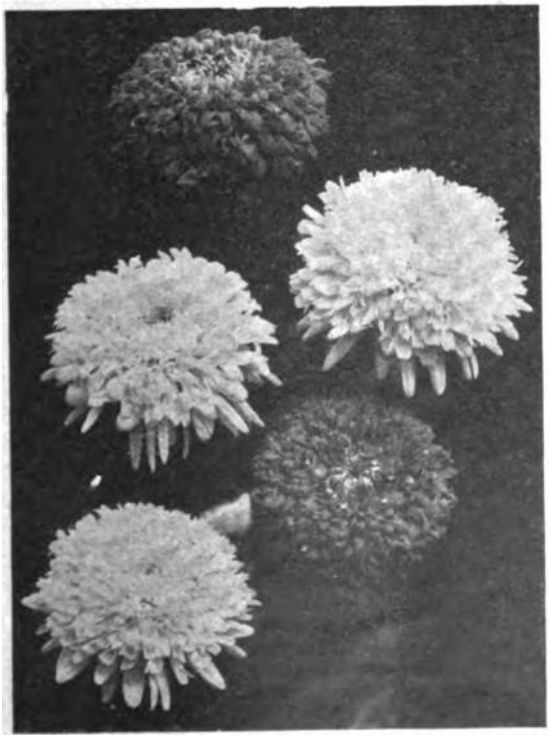
When planting pyrethrums for border decoration, they should be placed in clumps of three or five—unless the border be very narrow—allowing a space of 12 to 15ins. between the individual plants. Where they are grown in a plot for cut flowers, a proportionately greater space should be left between the rows to allow of hoeing and other general details of cultivation, as well as to give one space to get among the plants when cutting.

There are two types of pyrethrums, double and single, and it is purely a matter of personal taste as to which is considered the best. I prefer the singles as being of greater elegance, but it cannot be gainsaid that a really good double is a magnificent flower, and will last much longer in water than a single.

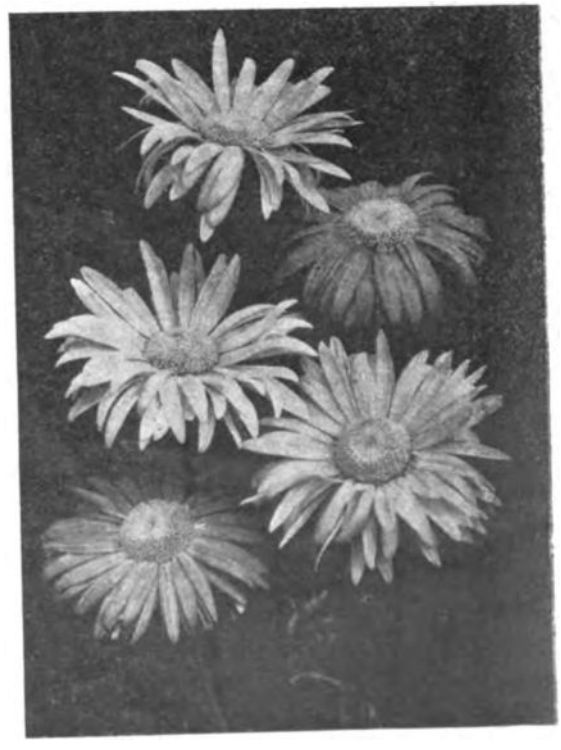
Among the single forms, the new Eileen May Robinson must take pride of place. It is indisputably the finest pink, bearing large flowers of a bright rich pink shade, and is, moreover, a vigorous-growing sort. Previous to this Agnes Mary Kelway was considered the best pink, and it is still a variety to be reckoned with. A real pure white is somewhat of a rarity among the singles, but in White Lady the want is satisfied, and Snow White and Starlight can also be recommended in this class. Perhaps the most gorgeous of all pyrethrums is James Kelway, with splendid scarlet crimson blossoms, the petals having a wonderful velvety texture. Two others of strikingly brilliant colouring are Langport Scarlet and General Gaselee, the latter being the more suitable for general planting. In varying shades of pink are Apollyon, a persistent bloomer; Lord Milner, Pinkie and Hamlet. One of the best late-flowering sorts is General French, with rich telling maroon-crimson flowers; while three exceptionally early varieties are Comet, bright carmine; Mrs. Bateman Brown, rich purple crimson; and Princess of Wales, of a lovely flesh pink colour.

Coming to the double varieties, Queen Mary is one of the leading sorts in this section, very free to flower and bearing salmon-pink flowers. Mont Blanc is another free-flowering sort, with white flowers, as also have Aphrodite and La Neige. The earliest of all whites is Carl Vogt, with extra large and pure white blossoms. With brightly coloured flowers, Capt. Nares, bright crimson; Lord Rosebery, scarlet; J. N. Twerdy, deep maroon; and Melton, deep crimson, are all sure to find favour, while others will be found in a good trade list.

Two singles which represent a distinct and very attractive break in their class are Kenneth Kelway, rose pink; and Mrs. James Kelway, bright pink, both having the curiously twisted "cactus" petals that have rendered so popular certain types of dahlia and cineraria. B.



A SELECTION OF DOUBLE-FLOWERED VARIETIES INCLUDING THE DEEP MAROON J. N. TWERDY.



THE SINGLE-FLOWERED VARIETIES WITH THEIR BRIGHT COLOURS ARE FULL OF GRACE AND CHARM.

Ferns for Room Decoration.

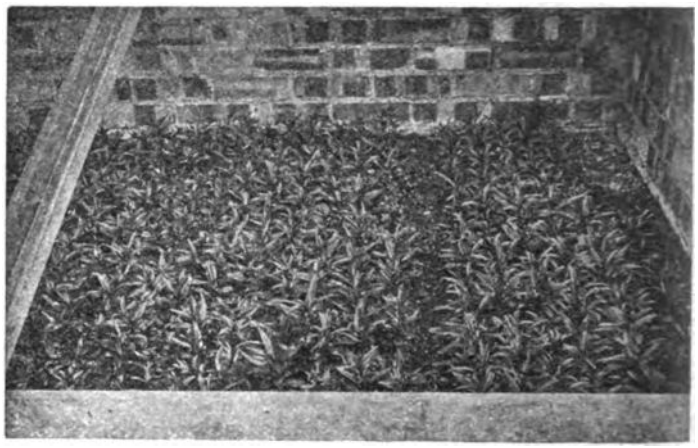
WELL grown ferns in pots are undoubtedly attractive and decorative, and people are tempted to adopt them for the embellishment of rooms and halls inside the house. Not all are a success, as every grower of ferns can guess, but many of the sturdy, robust kinds do exceedingly well under the trying circumstances. For example, the ribbon ferns or pteris kinds can be first-class table plants, and they do not deteriorate if treated on commonsense lines; the species cretica and some of its varieties, like Wimsetti, Childsii and so on are really fine, while the other species tremula and serrulata also do very well. The popular maidenhair ferns are not, as a rule, satisfactory, although Adiantum Mariesi has frequently been quite satisfactory. Asplenium bulbiferum and the hardy Cyrtomium Fortunei may be grown in pots or baskets inside, and even the robust Polypodium cristatum and P. aureum become really decorative inside a drawing room or entrance hall. In baskets Platycerium alcicorne, the stag's horn, and Davallia canariense, the hare's foot, prove interesting and attractive, and to complete the dozen we might add Asplenium Frizelli or one of the fine scolopendriums.

Overhauling the Garden Frame.

THE time of the year is close upon us when it will be necessary to consider utilising garden frames for winter; and in the meantime it is well to take stock of them, see what repairs (if any) are needed, and let the work have attention.

Exposed to all weather, frames ought to be overhauled at least once a year, and those not on a brick foundation receive a coat or two of paint at least every other year.

There is nothing lost in keeping frames well painted. Where glass has become broken, repairs will require to be made good and possibly puttying will be necessary to make water-tight other squares of glass. Too often one notices, where the box holding the lights is constructed of wood, that it is placed on the ground, and, unless kept well painted with good oil paint, rot soon sets in. One may lengthen the life of a frame considerably by placing the framework on a layer of bricks, or—if procurable — sleepers, the latter being given, every two years or so, a thorough dressing of carbolineum or similar mixture made from tar, which is a good preservative in which insect pests cannot live. If the frame is simply used for wintering plants in pots, all that will be needed after painting will be to renew the bed of ashes for them to stand on. If, on the other hand, it is intended to plant cuttings in a bed within the frame and the present soil has been there some time, it may be in that state commonly called "sour." In these circumstances it will be best to remove it and substitute fresh material as, for instance, loam and sand, with possibly leaf-mould added, according to what needs to be put in. The glass itself should be thoroughly cleansed from grime, so that it will not impede light. Work of this description undertaken now is better than deferring it to the last moment.



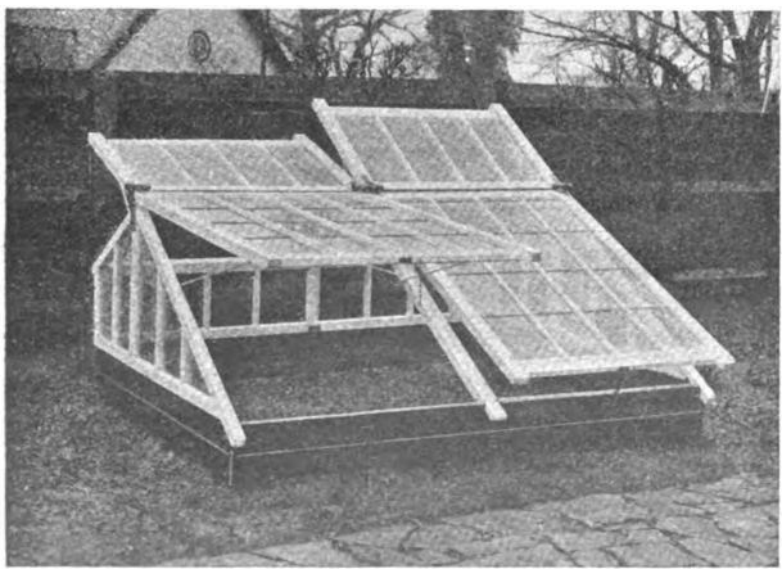
PROTECTION SHOULD BE GIVEN TO BEDDING PLANTS IN FRAMES.

A Useful Material for many Garden Purposes.

SAND is essential in the garden for lightening and draining soils. In pots or boxes sand keeps the soil in a compact state (a point of great importance where cuttings are concerned), and yet renders it porous enough for drainage. Another thing that sand does is to prevent the contact of cuttings or the roots of tender plants with fermenting material or strong manures in the soil. Sand always makes a heavy loam lighter and brings it into a better state for practically all kinds of plants. For pot-work silver or white sand is generally favoured, and this should be used in as coarse a condition as possible. Very fine sand is useful as a surface for cutting pots, but it is not good for mixing with the soil, as it tends to check free drainage. Clean road grit is a coarse quality of sand, and this is extremely useful for working into land that is on the heavy side. River and coast sand may also be used, though the latter should first of all be washed and exposed to the weather to get rid of the salt. Red sand contains too much iron to make it suitable for potting purposes, but by repeated washings it may be freed of the excess. When most of the red colouring has gone, the sand will prove as useful as any other kind.

Destroying Colt's Foot.

PROBABLY the most troublesome of all weeds to eradicate from a garden is the colt's foot (Tussilago Farfara). The rootstocks of this plant branch below the surface of the ground and extend to a considerable depth. It is practically impossible to uproot the colt's foot by ordinary digging and trenching, and to dig up the plants entirely would involve a prodigious amount of labour. By far the best plan is to keep on hoeing out the shoots of the plant whenever these appear. Quite the best time to do this is in the spring when the flowers are out and before they have actually started to set seed. In this way the trouble arising from the scattering of the seeds will be avoided and, if the hoeing is done with vigour, many of the leaf-buds on the rootstock just below the surface will be damaged, and possibly destroyed. Repeated hoeing down of the leaves, and not only in the spring but also in the latter part of the year, will so weaken the plants that they will eventually die out altogether.



A USEFUL FRAME FOR WINTERING TENDER PLANTS.

Petunias: Fine Window Plants.

ONE of the best window plants is the petunia, which makes a fine show in pot or box. The seed may be purchased next month and sown thinly on a nice even surface in a well drained, shallow box filled firmly with fine sandy soil in February or March. Cover the seeds lightly with sand. Water and place in a close frame near the glass, or place inside the window and cover with a sheet of glass or paper. Give air when the seedlings appear. When the third leaf has formed, the seedlings will be ready to prick into small pots. When the plants have filled the pots with roots they may be shifted into larger pots. They may be grown in a cold frame or window in a room, and hardened off as gradually as possible towards the end of May. They will be ready to plant into the outside window boxes in the opening week of June. Water as required to keep the plants in growth or bloom. The flowering period extends to about the end of September.

GARDENING IN TOWN AND SUBURB

BY R. SUDELL, *Organising Secretary of the London Gardens Guild.*

Rose Planting.

THE gardener's adage, "Plant when the sap is on the move," is a good guide for all hard-wooded plants. November and December are the ideal months for rose planting. The roots have then time to become established, and the pruning can be done at the correct season—the following spring.

How to Plant.

It pays to spend a little time in preparing the soil. Just to cut a hole in hard soil is to invite disaster. Roses must have plenty of root run. A hole should be made where the rose is to be planted. The under layer should then be well broken up, and lime and decayed manure (leaves or any decomposed organic substance will do) worked into the soil. This should be covered with a little fine soil, and the hole is then ready for the plant.

Place the rose in position, and carefully cut away any broken or bruised roots with a sharp knife. Spread out the roots well, and cover them with soil. The depth to plant can be seen by the previous soil mark.

Clay Soil Suitable.

I am often asked if clay soil is good for roses. It is quite good—that is if the land is well drained and the soil well dug before the planting is done. The finest roses I ever saw—at Latham Hall, in Lancashire—were growing in a stiff clay soil. The essential thing is that it should be well dug, for in this, as in many other things, it is the spade work that counts.

These hints on planting apply to all roses, but in the case of standard roses, a strong stake, standing the same height as the main stem, is necessary. The stake should be put in before the roots are covered, and a little extra treading to firm the soil after planting is advisable. Standard roses are excellent for small gardens, as they allow many other plants to be grown beneath them—for example, pansies, alyssum, etc.

Choice of Plants.

Varieties of roses become more and more numerous, and it is not easy to advise which to grow. There are actually more than a hundred different species, but only a few have entered into the parentage of our garden types. Even among those under cultivation, there is a world of difference between some that are good show types, and those suitable for the amateur's garden. You might choose one such as "Dainty Bess" on the show table, and perhaps you would find it had a "fit of sulks" in your own garden. It is far better to select only kinds that are fairly sure to succeed, especially if you have a town or suburban garden, and some which will give satisfaction, even under such conditions, are these:—

Climbing Roses.—Excelsa (red), Albéric Barbier (creamy white), Dorothy Perkins (pink), Gloire de Dijon (yellow salmon), American Pillar (pink), Blush Rambler (blush) and Hiawatha (crimson).

Bedding Roses.—General McArthur (crimson), Ophelia (flesh pink), Mme. Abel Chatenay (salmon), Sunburst (yellow), caroline Testout (pink), F. K. Druschki (white).

Fragrant Roses.—Mrs. J. Laing (rosy pink), La France (silvery rose), Hugh Dickson (crimson), George Dickson (crimson).

Winter Protection.

Tea and hybrid roses are sometimes injured by the frost, particularly in the north of England and Scotland. A few evergreen twigs, bracken, or strawy litter placed round the stems during severe weather will prevent this damage. No pruning should be done until spring.

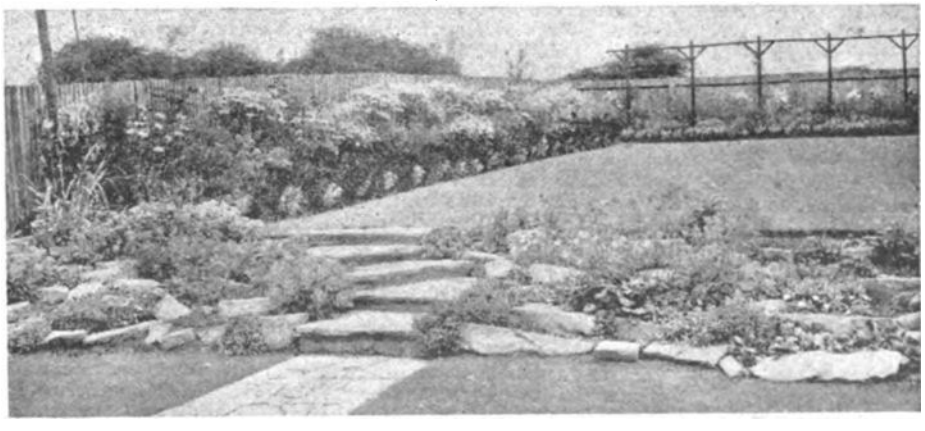
DECEMBER in the TOWN GARDEN.

WHAT TO DO THIS MONTH.

1.—*Clear tops from herbaceous borders, and fork over the soil.*
2.—*Roll lawns occasionally.*
3.—*Examine bulbs in store, such as begonias, gladioli and dahlias. Remove unsound specimens.*
4.—*Put a handful of fine ashes over the crowns of delphiniums.*
5.—*Pyrethrums to protect from slugs.*
6.—*Prune and nail wall trees.*
7.—*Spray fruit trees with caustic wash (caustic soda at the rate of 1lb. to 10 gallons of water).*
8.—*Burn any twigs or leaves attacked by fungoid diseases.*
9.—*Keep grease bands sticky.*
10.—*Draw a little soil around young cabbages.*
11.—*Complete earthing-up celery and leeks.*
12.—*Examine onions, potatoes, etc., in store.*
13.—*Lift parsnips and Jerusalem artichokes as required.*
14.—*Cut down asparagus tops, and top-dress beds with manure.*
15.—*Overhaul tools, and grease blades of lawn mower.*
16.—*Sharpen pea and bean sticks.*
17.—*Prepare labels for seed sowing in spring.*
18.—*Wash the glass of cold frames and greenhouses, using a disinfectant soap.*
19.—*All garden structural alterations should be completed.*
20.—*Order seed and plant catalogues. (Advertised goods are best.)*

Novel Steps.

THE treatment of a garden with different levels calls for much ingenuity on the part of the designer. Nothing is better suited for retaining a bank than this form of rockery. In the example illustrated, the steps are given a twist to the left, as a change from the usual. The feature is quite in keeping with a garden used solely for pleasure; but between, say, two large stretches of lawn, the straightforward type of steps would be more suitable. Now is the best time for effecting changes in the structure of the garden, and especially for constructing rockeries which need to settle down before being planted in spring.



A LOW ROCKERY RETAINING BANK USED TO ADVANTAGE TO BREAK THE LEVELS IN THE DIFFERENT PARTS OF THE GARDEN.
The steps, giving a twist to the left, are a pleasant feature of the bank.

Flower Pots, New and Old.

FLOWER pots vary in size from 2ins to 22ins. in diameter, and in depth from 2ins. to 18ins. Convenient sizes for the small greenhouse are 3½ins. in diameter, known as 60's in the trade; 5ins. in diameter, known as 48's; 7ins. in diameter, known as 28's; and 10ins. in diameter, known as 12's. Of course, there are sizes in between these. New pots should always be soaked in water and then allowed to dry before use; otherwise the roots cling to the sides and cause trouble when it is desired to knock the plant out of the pot.
